Multiple sclerosis, or MS, is a chronic autoimmune-inflammatory disease of the central nervous system that affects approximately 2.9 million people worldwide. Successful management of MS requires comprehensive therapeutic intervention that is appropriately tailored. Selecting appropriate treatments for MS remains problematic because of the large clinical and subclinical variation in disease course among patients. Over the past few years, drug repurposing, the use of established medications for new therapeutic applications has been increasingly recognized as a precious strategy in MS research. It provides a faster and less costly alternative compared with classic drug development. Numerous medications that were created for other ailments but have specific immunomodulatory, anti-inflammatory, or neuroprotective properties are being actively studied for their potential to treat multiple sclerosis. Agents such as S1P receptor modulators, kinase inhibitors, and metabolic regulators have exhibited promise in increasing neuroprotection, controlling immune activation, and enhancing remyelination both at the laboratory level and in clinical trial settings. In parallel, drug discovery and personalized medicine in MS have been further transformed by artificial intelligence. Advanced machine learning and deep learning systems interpret large-scale biological data sets, forecast drug-target relationships, and accelerate strategies for repurposing drugs. AI-driven approaches further allow uncovering novel therapeutic targets through integration of multi-omics information with neuroimaging and more accurate patient stratification toward personalized treatments. This review underlines advances in drug repurposing and emphasizes the significant role of AI in accelerating drug development toward better treatments for MS.

## SMART FLOOR-CLEANING COMPOSITION WITH VISUAL CLEANLINESS INDICATOR

VINOD M THAKARE
Nagpur College of Pharmacy, Wanadongri,
Hingna Road, Nagpur-441110

The invention discloses a cleaning composition and method that provide a visible, real-time indication of floor cleanliness via a triggered color change, enabling users to confirm effective soil removal and endpoint sanitation without auxiliary devices. The formulation integrates surfactant systems with pH-responsive or redox-responsive dyes, optionally immobilized on or microencapsulated with carriers, to transition between distinct colors as the surface condition shifts from soiled to clean and near-neutral, or as active antimicrobial strength decays or reaches target efficacy. The indicator phase may employ sulfonephthalein, phthalein, azo, or anthocyanin dyes tuned to change within predefined pH windows correlated to cleaning endpoints, or redox-coupled systems that respond to oxygenation or residue depletion, ensuring clear visual contrast under typical floor-care conditions. The composition can be delivered as a concentrate, ready-to-use liquid, foam, or wipe, and is compatible with common substrates including tile, stone, vinyl, and sealed wood. In some embodiments, the dye is bound to a solid or polymeric substrate to stabilize response, avoid staining, and provide at-a-glance verification of in-use concentration and antimicrobial activity thresholds. This approach reduces chemical overuse, minimizes rework, and standardizes cleaning quality across domestic, institutional, and industrial settings by coupling chemical functionality with robust visual feedback. Environmentally preferable embodiments incorporate biodegradable surfactants and low-toxicity indicators, maintaining optical clarity and stability over typical storage intervals while delivering a reliable, reversible or irreversible color signal matched to the desired cleaning performance criteria.

## DESIGN, SYNTHESIS AND PHARMACOLOGICAL EVALUATION OF ISOXAZOLE CONTAINING 1,2,4-TRIAZINE AND ITS DERIVATIVES

Yamini Bhongekar, Disha Dhabarde, Jagdish Baheti
Kamla Nehru College of Pharmacy (RTMNU)
Butibori, Nagpur, Maharashtra-441108
yaminibhongekar@gmail.com

This research centers on the design, synthesis, and pharmacological assessment of derivatives of 1,2,4-triazine that contain isoxazole. The field of pharmaceutical chemistry combines essential concepts from medicinal chemistry, chemical synthesis, and computational drug design to create biologically active compounds with enhanced therapeutic capabilities. As a significant category of six-membered heterocyclic compounds with three nitrogen atoms, 1,2,4-triazines showcase a variety of biological activities, such as anticancer, antioxidant, and anti-inflammatory effects. Their capacity to modulate kinases, inhibit lipid and protein kinases, and interact with critical molecular targets underscores their importance in the development of anticancer drugs. In this investigation, a collection of N-[5-(substituted phenyl)-1,2-oxazole-3-yl]-5,6-diphenyl-1,2,4-triazine-3-amine derivatives were devised using computational methods and assessed through SwissADME and molecular docking analyses. In-silico findings revealed that all designed compounds were adhered to Lipinski's rule of five, while docking studies against anticancer and antioxidant targets indicated strong binding affinities, particularly for proteins 8HUO and 3HBS. The synthesized derivatives underwent further characterization through physicochemical and spectroscopic techniques. Their antioxidant effectiveness was evaluated using nitric oxide scavenging and DPPH assays, where all derivatives demonstrated considerable free-radical scavenging capabilities compared to ascorbic acid. The anticancer

ISBN: 978-81-980623-8-3

potential of selected compounds (N-[5-(4-Methoxylphenyl)-1,2-oxazole-3-yl]-5,6-diphenyl-1,2,4-triazine-3-amine and 2-{3-[(5,6-Diphenyl-1,2,4-triazin-3-yl)amino]-1,2-oxazole-5-yl}phenol) was investigated against the MDA-MB-231 breast cancer cell line using the MTT assay, indicating significant cytotoxic effects. In summary, the results validate that the synthetic approach taken is effective for developing isoxazole-linked 1,2,4-triazine derivatives with encouraging anticancer and antioxidant properties, emphasizing their potential as lead candidates for future drug development.

## *IN SILICO* DOCKING OF LECITHIN FOR ANTI-ALZHEIMER'S ACTIVITY

Yarabati.meena, Gindi Sumalatha
Department of Pharmacology, Vikas Institute of Pharmaceutical Sciences, Nidigatla near airport,
Rajahmundry, East godavari district, Andhra Pradesh, India 533102
yarabatimeena669@gmail.com

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by memory loss, cognitive decline, and neuronal degeneration, primarily associated with the aggregation of β-amyloid (Aβ) peptides and hyperphosphorylation of tau proteins. The search for safe and effective therapeutics has led to increasing interest in natural compounds with neuroprotective potential. Lecithin, a phospholipid-rich compound found in soybeans and eggs, is known for its role in enhancing cholinergic transmission and improving cognitive function.In the present study, in silico molecular docking techniques will be employed to evaluate the interaction of lecithin with key Alzheimer's disease targets, including acetylcholinesterase (AChE), butyrylcholinesterase (BChE), β-secretase (BACE1), and amyloid beta (Aβ) peptide. The docking studies were performed using AutoDock Vina and visualized using Discovery Studio to predict binding affinities and interaction patterns. Lecithin demonstrated significant binding affinity toward AChE and BACE1, suggesting its potential to inhibit cholinesterase activity and amyloid plaque formation. Hydrogen bonding and hydrophobic interactions were found to stabilize the lecithin–enzyme complexes, indicating possible neuroprotective effects.The computational findings suggest that lecithin could serve as a promising lead compound for the development of novel therapeutics against Alzheimer's disease. Further *in vitro* and *in vivo* studies are warranted to validate its efficacy and safety profiles.

**Keywords:** Lecithin, Alzheimer's disease, *in silico* docking, acetylcholinesterase, BACE1, neuroprotection.

## A NOVEL LEAN SIX SIGMA APPROACH AND SUSTAINABLE HPLC METHOD FOR SIMULTANEOUS ESTIMATION OF SELECTED ANALGESIC COMBINATION DRUGS IN PHARMACEUTICAL FORMULATIONS

Yenduri Suvarna
Department of Pharmaceutical Chemistry & Analysis,
Sri Adichunchanagiri College of Pharmacy, Adichunchanagiri University,
B.G. Nagara, Karnataka
suvarna.ph52@gmail.com

In the present study, Lean Six Sigma (LSS) principles and Green Analytical Chemistry (GAC) metrics were used to develop and validate a statistically optimized and environmentally sustainable Reverse Phase High-Performance Liquid Chromatography (RP-HPLC) method for the simultaneous determination of paracetamol, caffeine, diphenhydramine hydrochloride, and phenylephrine hydrochloride in pharmaceutical formulations. The Box–Behnken Design (BBD) of the Response Surface Methodology (RSM) framework optimized wavelength, flow rate, and column temperature. An eco-friendly mobile phase of ethanol and 0.1% formic acid (50:50, v/v) replaced harmful solvents. The approach was tested for validation parameters as per ICH Q2(R1). MoGAPI, CaFRI, RAPI, RGB Fast, CACI, and Spider Chart Analysis assessed technique sustainability and greenness. Method performance was statistically assessed using Six Sigma process capacity indicators (Cpk). Optimal separation occurs at 1.5 mL/min flow rate, 41.9 °C column temperature, 218 nm detection wavelength, with a composite desirability of 0.874. The method revealed high linearity (2-150 µg/ mL, $r^2 > 0.999$), accuracy (%RSD < 2%), and recovery (98-101%). Compared to established methodologies, the greenness evaluation showed enhanced eco-efficiency (MoGAPI = 91, CaFRI = 89), reducing solvent usage, waste, and carbon footprint. Six Sigma analysis showed good process capacity and method robustness for all analytes with Cpk > 1.33. Lean Six Sigma and Green Analytical Chemistry were used to create a proven, cost-effective, and environmentally friendly RP-HPLC method for regular pharmaceutical quality monitoring. Through sustainability, quality, and analytical performance in a forward-thinking paradigm, the plan sets a standard for future chromatographic technique development.

## INTEGRATION OF ANALYTICAL GREENNESS AND AQBD FOR DEVELOPING AN ECO-COMPATIBLE RP-HPLC METHOD FOR EMTRICITABINE, TENOFOVIR AND EFAVIRENZ

Shrikrishna S. Maske, Amol A. Joshi
ASPM's K. T. Patil College of Pharmacy, Siddharth Nagar,
Barshi Raod, Dharashiv- 413501, Mahabharata, India.
shrikrishnasmaske@gmail.com

Emtricitabine, Tenofovir, and Efavirenz are widely used together in fixed-dose antiretroviral therapy. Because Efavirenz has a narrow therapeutic window, accurate quantification of all three drugs is essential to maintain patient safety, therapeutic efficacy, and consistent product performance. To date, no reported analytical method has integrated the principles of Green Analytical Chemistry or employed an Analytical Quality by Design (AQbD) strategy for this particular combination. In this study, we developed and validated a novel, environmentally conscious RP-HPLC method capable of simultaneously estimating all three drugs. Chromatographic separation was achieved on a Cosmosil C18 column (250 mm × 4.6 mm, 5 µm) using water and methanol as the mobile phase components. Methanol was ultimately selected for its superior performance, and to enhance the sustainability of the method, complete solvent recovery and recycling were implemented to minimise ecological burden. The method was validated in accordance with ICH guidelines and demonstrated excellent linearity, with correlation coefficients of Emtricitabine 0.9995, Tenofovir 0.9998, and Efavirenz 0.9992. The greenness of the method was further evaluated using NEMI, GAPI, and the AGREE metric, all of which confirmed its environmentally friendly attributes. This investigation is distinguished by its successful integration of sustainability considerations with the systematic, risk-based approach of AQbD. To the best of our knowledge, this is the first analytical method for this antiretroviral combination that incorporates both frameworks. The proposed method has strong potential for routine quality control and regulatory use, offering reliable quantification while aligning with global environmental sustainability initiatives.

**Keywords:** Emtricitabine, Tenofovir, and Efavirenz, AQbD and Green analytical chemistry

## MOLECULAR DOCKING AND TOXICITY ASSESSMENT OF COUMARIN DERIVATIVES AS POTENTIAL EBOLA VIRUS INHIBITORS

Deepthi M N, Naga Prashant Koppuravuri
Department Of Pharmaceutical Chemistry, Faculty of Pharmacy,
Sri Adichunchanagiri College of Pharmacy, Adichunchanagiri University,
B G Nagara-571448
deepthideeps192002@gmail.com

Ebola virus remains a critical global health challenge due to its high fatality rate and limited treatment options. Coumarin derivatives are known to exhibit diverse biological activities including antiviral potential, making them attractive scaffolds for drug discovery. Computational approaches provide rapid and cost-effective tools for exploring new antiviral candidates. In this study, molecular docking was employed to assess the interaction of coumarin derivatives with a key ebola viral protein. This study aims to evaluate a series of ten coumarin derivatives for their inhibitory activity against the Ebola virus protein (PDB ID: 6YU8) using molecular docking and computational toxicity profiling. The goal was to identify the most potent and safe derivative suitable for further drug development. Molecular docking studies were carried out using PyRx software to predict binding affinities of coumarin derivatives with the Ebola viral target (6YU8). Toxicity parameters, including organ-specific and carcinogenic risks, were evaluated using ProTox-3.0, while

ISBN: 978-81-980623-8-3

Swiss ADME was used to assess pharmacokinetic features such as Lipinski's rule of five, blood-brain barrier permeability by boiled egg model and Synthetic accessibility scores (1-10 scale) were analyzed to estimate the ease of chemical synthesis. All coumarin derivatives displayed notable binding affinities ranging from –6.0 to –8.4 kcal/mol, with the highest docking score of –8.4 indicating strong interaction with the Ebola target protein. The toxicity class ranged from 4–5, showing low toxicity for most compounds. However, compound 8 exhibited moderate organ specific toxicities. All derivatives satisfied Lipinski's rule of five and were predicted to cross the blood-brain barrier, supporting favorable drug-likeness.Synthetic accessibilty scores between 2 and 4 confirmed that all derivatives are easily synthesizable using standard laboratory methods. The results indicate that coumarin derivatives possess promising antiviral potential against the Ebola virus, with generally acceptable safety and pharmacokinetic properties. The lead compound (–8.4 kcal/mol) is a strong candidate for further biological evaluation, whereas compound 8 requires optimization to reduce toxicity risks.

## DESIGN AND DEVELOPMENT OF 4,5-DISUBSITUTED PYRIMIDINE DERIVATIVES AS EGFR INHIBITORS TARGETING NON-SMALL CELL LUNG CANCER (NSCLC)

Rohit Pal[1], Gurubasavaraja Swamy Purawarga Matada[1]
[1]Integrated Drug Discovery Centre, Department of Pharmaceutical Chemistry, Acharya & BM Reddy College of Pharmacy, Bengaluru 560107, Karnataka, India
gurubasavarajaswamy@gmail.com

Non-small cell lung cancer (NSCLC) driven by mutations in the epidermal growth factor receptor (EGFR) remains a major therapeutic challenge, particularly due to the emergence of drug resistance. In this study, a new series of 2,4-disubstituted pyrimidine derivatives (Ri–Rxii) was designed, synthesized, and evaluated as potential EGFR inhibitors. Among these, compound Riv demonstrated the most potent antiproliferative activity against both wild-type and mutant EGFR-driven NSCLC cell lines, including EGFRL858R/T790M and the drug-resistant EGFRL858R/T790M/C797S variants, exhibiting low IC50 values and minimal cytotoxicity toward normal cells. Mechanistic studies revealed that Riv induced cell cycle arrest at the S and G2/M phases and promoted apoptosis in a dose-dependent manner. Western blot analysis confirmed significant suppression of the EGFR/Akt signaling pathway, with Riv markedly reducing the phosphorylation levels of EGFR and Akt. In addition, Riv exhibited strong antioxidant activity, surpassing ascorbic acid in both DPPH and ABTS assays, thereby indicating its potential to mitigate oxidative stress. Molecular docking and molecular dynamics simulations revealed stable binding interactions with key active-site residues of EGFR, while DFT analysis indicated favorable electronic properties supporting its reactivity profile. Furthermore, in-silico ADMET predictions suggested good pharmacokinetic behavior and low toxicity risk. Collectively, these findings identify Riv as a promising, safe, and effective EGFR inhibitor capable of overcoming drug resistance in the treatment of NSCLC.

School of Pharmacy, Rungta International Skills University, Bhilai 490024, Chhatisgarh, INDIA
nitinsahu8781@gmail.com

Rheumatoid arthritis (RA) is a debilitating autoimmune disorder that causes chronic inflammation of the synovial tissues and subsequent deterioration of the joints. Corticosteroids are effective at dampening inflammation; however, administration via systemic routes leads to concerns about rapid systemic clearance, dose-frequent delivery, and potential adverse effects. To minimize these potential problems, we undertook to prepare a sustained intra-articular delivery system by encapsulating corticosteroids in lipid-based nanoparticles made by emulsification–solvent evaporation. Our final optimized formulation produced nanoparticles that were 110–210 nm in size, had a high drug-loading content, and sustained the controlled release of the corticosteroid for up to 12 hours. Although we reported our initial formulation period of sustained drug availability for only 12 hours, we incorporated these nanoparticles into an in-situ gelling matrix with sustained drug delivery for up to 7 days. The final formulation is favorable in a range of physiochemical parameters: pH, viscosity, texture, gelling ability, and spreadability. In summary, the nanogel system is suitable to deliver a corticosteroid for a targeted and long-acting purpose in the case of RA. Further, the potential to reduce systemic exposure should improve therapeutic outcomes.

**Keywords:** Rheumatoid arthritis, Corticosteroids, Lipid nanoparticles, In situ gel, Sustained drug delivery.

## PREPARATION AND EVALUATION OF HERBAL METALLIC NANOCOMPOSITES USING GREEN SYNTHESIS FOR THERAPEUTICS APPLICATIONS

Pramod Badale, Komal Chavan, Vinita Kale, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur
badalepramod@gmail.com

This study reports the green synthesis of magnesium oxide (MgO) and titanium dioxide ($TiO_2$) nanoparticles using Syzygium aromaticum (clove) extract as a natural reducing and stabilizing agent. The phytochemical constituents of clove, including flavonoids, alkaloids, tannins, saponins, and phenolics, facilitated nanoparticle formation under mild conditions. Successful synthesis was confirmed by UV-Visible spectroscopy, which exhibited a characteristic absorption band at 281.2 nm, and FTIR analysis, which identified functional groups such as O-H, C=O, and metal-oxygen bonds. Particle size analysis revealed an average size of 202 nm, while zeta potential values confirmed good stability. X-ray diffraction (XRD) displayed sharp peaks within the 20°-40° range, confirming crystallinity and phase purity. Scanning electron microscopy showed predominantly spherical to irregular porous structures, indicating high surface area favorable for biomedical applications. Incorporation of 1-2.5% Clove-MgO nanoparticles into glass ionomer cement (GIC) significantly enhanced compressive strength and surface hardness. The nanoparticles demonstrated high entrapment efficiency (92.58%) and drug content (84.65%). This study demonstrate that green-synthesized MgO nanoparticles are biocompatible, sustainable, and effective reinforcements for dental restorative materials. Their ability to improve mechanical performance enhances their potential in minimizing secondary caries and improving long-term clinical outcomes in restorative dentistry.

**Keywords:** Magnesium oxide NPs, Titanium dioxide Nps, Biocompatible, Entrapment efficiency.

## IMPROVING ORAL BIOAVAILABILITY OF LULICONAZOLE WITH SOLID SELF-EMULSIFYING DRUG DELIVERY SYSTEM (S-SEDDS) USING HOT MELT EXTRUSION (HME) TECHNOLOGY

Vamshi Krishna Tippavajhala* and Ashay M. Shailendrakumar
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences,
Manipal Academy of Higher Education, Manipal, Karnataka-576104, India
vamshi.krishna@manipal.edu

The treatment of systemic fungal infection is one of the challenges in the public health domain. Recently published reviews and clinical reports have addressed the issue of fungi becoming resistant to the commonly used antifungal drugs. However, these documents have reported a better activity of Luliconazole against resistant strains. Based on this evidence, the current research work was conducted to formulate, optimize and evaluate Solid Self-Emulsifying Drug Delivery Systems (SEDDS) of Luliconazole. Liquid SEDDS are known for enhancing the solubility of BCS class II drugs like Luliconazole. Quality by Design (QbD) approach was used to optimize these liquid SEDDS by applying KCV design in Design Expert software. To enhance stability of these liquid formulations, they were solidified using Hot Melt Extrusion technology. This research work was focused on the comparative study of in vitro and in vivo activities of Solid SEDDS versus Liquid SEDDS. In vitro antifungal study showed higher zones of inhibition for Solid SEDDS compared to the Liquid SEDDS. In vivo pharmacokinetic and pharmacodynamic evaluation of Solid SEDDS demonstrated improvement in oral bioavailability and enhanced antifungal activity against Candida albicans respectively.

**Keywords:** Solid SEDDS, Liquid SEDDS, Hot Melt Extrusion, Luliconazole.

## IN-SILICO AND IN-VITRO ANALYSIS OF NOVEL SILYMARIN METAL COMPLEXES AS A POTENTIAL CANDIDATE FOR THE TREATMENT AGAINST MYCOBACTERIUM TUBERCULOSIS AS ANTI-TUBERCULAR AGENTS

Amsmrit Borah and Paramita Das
Department of Pharmaceutical Chemistry, Krupanidhi College of Pharmacy, Chikka Bellandur, Bengaluru, Karnataka, 560035
amsmritborah.pharmacy@gmail.com

The clinical use of metal complexes is well-established and have significant potential for developing novel Metallo pharmaceutical agents. The present study aimed to investigate silymarin-based metal complexes as potential inhibitors of Enoyl acyl carrier protein reductase (ENR), a validated drug target in Mycobacterium tuberculosis (H37Rv). Molecular docking revealed that the silymarin complexes with metals $Cu^{2+}$, $Co^{2+}$, $Zn^{2+}$, $Ca^{2+}$ and $Hg^{2+}$ exhibited good binding score to ENR which are then synthesized and characterization was done by FT-IR, NMR, Mass, and powder XRD which confirmed coordination through the carbonyl group (C-22) and hydroxyl group (C-15). In-vitro anti-tuberculosis activity was assessed using the Microplate Alamar Blue Assay (MABA) and the results indicates that copper (MIC = 12.5 µg/ml) and zinc (MIC = 12.5 µg/ml) complexes demonstrated notable inhibitory activity against M. tuberculosis. Using GROMACS, molecular dynamic simulation was run and the results indicate that the complex with copper, the protein RMSD stabilized between 1.5–2.0 Å and the ligand RMSD gradually increased to ~2.4–2.7 Å with protein RMSF values remained low (<1.0 Å) in structured regions but showed higher fluctuations (~2.5–3.6 Å) in flexible loops and termini and with zinc, the protein reached equilibrium early, with RMSD values stabilizing between 1.5–1.8 Å and the ligand RMSD ranging from 1.0 Å to 6.0 Å with protein RMSF remained below 1.0 Å in stable regions but showed peaks (~2.6 Å) at flexible loops and termini. In-silico toxicity study was performed using Protox 3.0 web server and the result show minimum toxicity for all the metal complexes. In conclusion, silymarin–metal complexes represent promising candidates for the development of novel anti-tubercular agents. The integration of In-silico and In-vitro approaches highlights their potential for further preclinical evaluation.

**Keywords:** Silymarin, Metal complexes, Mycobacterium tuberculosis, Enoyl ACP reductase, Molecular docking, Anti-tubercular agents.

**DESIGN, DEVELOPMENT, AND EVALUATION OF 5-FLUOROURACIL MATRIX TABLETS USING NATURAL POLYMERS AS A SUSTAINED RELEASE DRUG DELIVERY SYSTEM**

Gayatri Sasane, Rohit khamlar, Dr. Rayala Swetha, Dr.Satish Polshettiwar
gayatrisasane46@gmail.com

This Current research focuses on designing and evaluating sustained release matrix tablets of 5-Fluorouracil (5-FU) utilizing natural polymers, specifically Fenugreek gum and Tamarind gum. Matrix tablets were developed using these gums singly and in combination, with in-vitro dissolution studies performed in simulated gastric fluid and phosphate buffer. Polymer blends provided improved control of drug release, reaching up to 94% over 10 hours, attributable to potential in-situ interpolymeric interactions. Physicochemical and stability assessments confirmed excellent formulation reliability, while FTIR and XRD analyses demonstrated absence of significant drug–polymer interactions and retention of 5-FU crystallinity. The results highlight natural gums as promising excipients for sustained release oral delivery of 5-FU, potentially enhancing cancer therapy and patient compliance.

**Keywords:** 5-Fluorouracil, sustained release, Fenugreek gum, Tamarind gum, natural polymers, matrix tablets, cancer therapy

**FORMULATION AND EVALUATION OF VORICONAZOLE NANOSUSPENSION FOR EFFECTIVE TREATMENT OF FUNGAL KERATITIS**

Kaveri Balasubramani, Selvakumar Arunachalam, Mohan Parasuraman
Vellalar College Of Pharmacy, Thindal, Erode-12
kaveribalasubramaniam08@gmail.com

Fungal keratitis, also known as keratomycosis, is an infection that affects the cornea, primarily targeting the corneal epithelium and stroma, and in severe cases leading to vision loss. Voriconazole, a modern triazole antifungal drug with a broad spectrum of activity, faces challenges such as poor water solubility and limited eye absorption when delivered through conventional formulations. To overcome these barriers, voriconazole nanosuspensions were developed using Eudragit RL 100 as a polymer carrier and Tween 80 as a stabilizer by solvent-injection technique. These nanosuspensions were thoroughly characterized for particle size, zeta potential, pH, drug excipients compatibility studies, HET-CAM Irritation and drug release behavior. The result shows that formulations had Particle size ranged from 155 to 285 nm with a positive surface charge (16.7 ± 0.2 mV), promoting strong corneal adhesion. The formulations exhibited suitable ocular pH (5.8–6.7) and viscosity (9.13 ± 1.2 cP), supporting prolonged retention on the eye surface. In vitro drug release studies showed sustained and controlled release from VCZ-NS3 (75.89% at 8 hours) compared to rapid release from traditional suspension (97.39% at 6 hours), implicating the polymer coating in modulation of drug release. Release kinetics followed the Higuchi model with a non-Fickian anomalous transport (n=0.685–0.776), indicating coupled erosion-diffusion mechanisms. These findings suggest that VCZ-NS enhances voriconazole penetration, improves bioavailability, and prolongs therapeutic action, representing a promising approach for effective fungal keratitis treatment.

**DEVELOPMENT OF LYOPHILISED FORMULATION OF TIGECYCLINE FOR ENHANCEMENT OF STABILITY**

Allam Tirushya Naidu, and G.Pavani
Department of Pharmaceutics, Bapatla College of Pharmacy, Bapatla-522101
tirushyanaidu@gmail.com

Drug Tigecycline in liquid Injection was found to be unstable. Therefore, it was planned to develop the lyophilized formulation for better stability and also to be line with RLD. The lyophilized cycle was optimized with direct four step freezing at -30°C and changing vacuum with post heat up to 40°C. From the compatibility studies results obtained, it was concluded that Drug Tigecycline for Injection 50mg was compatible with o 5mL clear glass USP Type I vial. o Bromobutyl rubber closure. o Nitrogen sparging Drug Tigecycline for Injection 50mg/vial Single Use Vials should be kept in carton to protect from light. The developed formulation was able to withstand three freeze thaw cycles without getting affected product quality. The formulation was stable for 3 Months when subjected to accelerated stability studies. In conclusion a stable formulation for drug Tigecycline was developed which was comparable to Reference Listed Drug Product (RLD), or Innovator. Tigecycline, a glycylcycline, acts by inhibiting protein synthesis at the level of the bacterial ribosome by blocking the binding of amino-acyl tRNA to the A site of the ribosome. Tigecycline has in vivo and in vitro antibacterial activity against a broad spectrum of pathogens. Tigecycline is active against bacterial strains that carry classical tetracycline resistant genes encoding either ribosomal protection or a tetracycline efflux pump.

**Keywords:** LYOPHILISED, TIGECYCLINE, RLD, Enhancement of Stability, compatibility

**DESIGN, DEVELOPMENT AND EVALUATION OF ANTI DIABETIC EMPAGLIFLOZIN DRUG LOADED NOVEL SNEDDS FORMULATION USING CENTRAL COMPOSITE DESIGN**

Shaik Davood Hussian, and Dr.K.Rajyalakshmi
Department of Pharmaceutics, Bapatla College of Pharmacy, Bapatla-522101
shaikdavood800@gmail.com

Empagliflozin is a model of drug belonging to BCS class-III, which has poor solubility in aqueous media. This work mainly focused on improving permeability of empagliflozin by developing them on LBDDS & SNEDDS. The solubility studies of various excipients like groundnut oil, coconut oil, sesame oil, Tween 80,60, Span 80 as Surfactant, PEG 4000,6000,8000 as co-surfactant were performed by U.V visible spectroscopy analysis. Groundnut oil: tween 80: peg 4000 were selected as snedds ingredients. Pseudo ternary plot diagrams were performed to optimize the effective combination of oil, surfactant, co-surfactant by preparing blank SNEDDS. From the pseudo ternary phase diagram, the best combinations that were in the nanoscale were selected for DOE. Using design expert software for design of experiments –central composite design (CCD) is used to optimize the effective combination of oil and Smix to formulate SNEDDS. From 15 runs and response (% Entrapment efficiency, % Transmission, Drug loading) performed with CCD. According to DOE, the runs were found to have highest drug content and good % Entrapment efficiency, % Transmission was selected for further optimization. (F1,F5,F10) Using the optimized self-emulsifying mixture, drug loaded liquid SNEDDS were evaluated in terms on phase separation, thermodynamic stability, drug release studies, etc. were characterized. In vitro drug release studies showed more than 95 % drug release in 30 minutes for all formulations. Droplet size analyzer, Poly dispersibility index, Zeta potential, SEM analysis was formed to (F10) formulation. Ex-vivo studies were conducted to detect the permeability through Non –everted gut sac method on goat kidney. L-SNEDDS exhibited good anti –diabetic activity. Empagliflozin L-SNEDDS is a promising approach to enhance drug permeability and improve patient compliance.

**Keywords:** SNEDDS, nanoscale, Empagliflozin, self-emulsifying time and anti – diabetic activity

**FORMULATION AND CHARACTERIZATION OF MFX-GOLD NANOPARTICLES LOADED IN-SITU GEL FOR THE TREATMENT OF BACTERIAL KERATITIS**

Nagendra Bhuwane, Preeti K Suresh
Faculty of Pharmacy, Shri Rawatpura Sarkar University, Raipur, C.G.
University Institute of Pharmacy, Pt. Ravishankar Shukla University, Raipur C.G.
nagendraassameer@gmail.com

Background and Aims: The aim of the present investigation is to prepare and evaluate Mfx-GNPs loaded in-situ gel-for ophthalmic drug delivery system for the management of bacterial keratitis. Materials and Method: The study is proposed to evaluate the anti-bacterial and anti-biofilm efficacies of Mfx-GNPs loaded in-situ gel. This article describes a systematic approach for the design, optimization, and characterization of Mfx-GNPs loaded in-situ gel. Optimization was performed using a 32 response surface approach, the effect of Concentration of Gellan gum (X1), Concentration of Chitosan (X2) and Concentration of Carbopol 940p (X3) content was optimized as independent variables, Viscosity at non physiological condition (Y1) and Viscosity at physiological condition (Y2)

ISBN: 978-81-980623-8-3

served as variables. The optimized formulation is characterized by EE, particle size, Fourier transform infrared spectroscopy (FTIR), Xray diffraction (XRD), differential scanning calorimetry (DSC), scanning electron microscopy (SEM), in vitro drug release study, antibacterial efficacy and antibiofilm activity. Results: The percentage of EE is 89%, the size is 56.25 nm, and the in vitro drug release is 92%. Mfx-GNPs loaded in-situ gel are fully prepared and can effectively release drugs in a sustained mode. Conclusion: The developed Mfx-GNPs loaded in-situ gel demonstrated sustained drug release, strong antibacterial and antibiofilm activity, and optimal physicochemical characteristics. This optimized formulation holds promising potential for effective ophthalmic delivery in treating resistant bacterial keratitis.

**BIOACTIVE DUAL-DRUG HYDROGEL: NITROFURAZONE AND ALOIN SYNERGY FOR ACCELERATED BURN WOUND HEALING**

Pooja Mittal
GITAM School of Pharmacy, GITAM (Deemed to be) University, Rudraram, Patancheru, Sangareddy District, Hyderabad-502329

Burn injuries are among the most challenging clinical problems, generally leads to infection if not treated properly, delayed healing, and compromised patient recovery. To address these multifaceted issues, we developed a smart dual-drug hydrogel that integrates Nitrofurazone, a potent antimicrobial agent, and Aloin, a phytoconstituent well known for its regenerative and anti-inflammatory properties. The hydrogel was formulated using a PVA–Chitosan semi-interpenetrating polymer network (IPN) which was selected for its biocompatibility, mechanical strength, and moisture-retention capacity. Optimization of the formulation ensured sustained drug release, ideal rheological properties, and structural integrity. Physicochemical characterization confirmed optimal thickness, folding endurance, swelling index, and smooth surface morphology (SEM). In vitro studies showed sustained dual-drug release and remarkable antibacterial activity against Staphylococcus aureus and Escherichia coli. In vivo experiments in a rat burn model revealed significantly faster wound closure, reduced infection, and enhanced tissue regeneration compared to conventional treatment. This innovative hydrogel dressing combines antimicrobial defence with skin-healing potential, offering a next-generation solution for burn care. Its synergistic design not only accelerates healing but also improves patient outcomes by reducing complications and recovery time.

**Keywords:** Burn wound therapy, Dual-drug hydrogel, Nitrofurazone, Aloin, PVA–Chitosan, Accelerated healing.

**MICROPLASTIC POLLUTION: A GROWING GLOBAL ENVIRONMENTAL AND PUBLIC HEALTH CHALLENGE**

Pandu Pragathi, Lakshmi Durga Bhavani Nuziveeti
Department of Pharmaceutical Analysis, Shri Vishnu College of Pharmacy (Autonomous), Andhra University, Bhimavaram, West Godavari District, Andhra Pradesh, India.
Pragathipandu33@gmail.com

Microplastic pollution impacts terrestrial, marine, and atmospheric systems and is becoming a major global environmental and public health concern. These particles, which come from primary and secondary sources, are common and could endanger ecological stability and human health. The sources, distribution, environmental destiny, and regulatory issues related to microplastics are examined in this paper. In order to comprehend exposure pathways and long-term effects, it highlights the necessity of multidisciplinary research, integrated waste management techniques, and public education. Effective policies that reduce plastic usage, improve recycling systems, and lessen environmental pollution must be implemented through coordination at the local, national, and international levels. Protecting ecosystems and guaranteeing a better future for people depend on addressing this unseen threat.

**Keywords:** Microplastics, global pollution, ecosystem impact, waste management, environmental policy, public health.

**FORMULATION OF NAIL POLISH AND IN-VITRO ANTI-FUNGAL ACTIVITY BY USING CLITORIA TERNATEA**

P Lakshmi Prasanna and P Srija Sravani
Department of Pharmacology, Shri Vishnu College of Pharmacy,Bhimavaram,Andhra Pradesh India- 534202.
prasanna.piridi@icloud.com

The current study looks at creating a herbal nail polish that uses anthocyanin extracts from Clitoria ternatea (butterfly pea) flowers. It also evaluates its antifungal activity in the lab. Nail polish is a common cosmetic product, but it can also serve as a possible treatment when combined with natural ingredients. Clitoria ternatea has a long history in Ayurvedic medicine for its various health benefits, mainly due to its flavonoid and anthocyanin content. These compounds have strong antioxidant, antimicrobial, and antifungal properties. In this research, we extracted anthocyanins from dried Clitoria ternatea petals using ethanol and Soxhlet extraction. We then performed a phytochemical screening, which confirmed the presence of alkaloids, flavonoids, tannins, saponins, phenols, and terpenoids. We mixed the extract into a nail polish base made of methyl cellulose, castor oil, silica, and stabilizers to ensure it remained stable, uniform, and visually appealing. We tested the finished nail polish for texture, adhesion, drying time, and stability. It showed no phase separation and kept its color. We assessed the antifungal activity of the anthocyanin extract using Candida glabrata cultures on potato dextrose agar plates with the well diffusion method. The results showed significant zones of inhibition at higher concentrations, confirming the antifungal potential of the formulation. This study shows that Clitoria ternatea anthocyanin extract can be effectively used in cosmetic products, providing both beauty and antifungal benefits. Further research on long-term stability and clinical effectiveness could help develop it into a practical commercial antifungal cosmetic product.

**Keywords:** Clitoris Ternatea, Anti fungal, Nail Polish, Herbal, Anthocyanins.

**FABRICATION AND CHARACTERIZATION OF MICROSPHERES OF AN ANTIDIABETIC DRUG THROUGH STATISTICAL OPTIMIZATION FOR ENHANCED BIOAVAILABILITY USING MULTIVARIATE POLYMERS: A COMPARATIVE ANALYSIS**

Nazia Khanam and Md Irshad Alam
Department of Pharmaceutics, The Oxford College of Pharmacy, Bangalore, Karnataka, India- 560068.
Bal Pharma Limited, Bangalore, Karnataka, India- 560099
nazia.khanam7@gmail.com

Bioavailability enhancement of Metformin hydrochloride (MFH) was performed through development of a Controlled Drug Delivery System (CDDS) by microspheres fabrication and characterization through implementing Box Behnken design (BBD) as the statistical tool. The multivariate polymeric inculcation comprised of natural, semi-synthetic and synthetic polymers for comparative analysis. Incorporation of natural and semi-synthetic polymers for MFH loaded microspheres were fabricated by ion- gelation technique, emulsion-solvent evaporation technique was used for natural and synthetic polymers and modified solvent evaporation method was employed for combination of semi-synthetic and synthetic polymers. Prepared microspheres were characterized for particle size, entrapment efficiency of drug and in-vitro study. Fourier transform infrared spectroscopy (FTIR), x-ray diffraction (XRD) detection, HPLC and H1 Nuclear magnetic resonance (NMR) quantification for optimized formulation. It was observed that application of response surface method software for BBD yielded most stable and spherical microspheres with mean particle size 268 µm and entrapment efficiency of drug 88.46% for the optimized formulation F6. We can conclude that coupling of MFH with semi-synthetic and synthetic polymers yielded most stable, cost-effective microspheres with enhanced bioavailability and controlled release effect. Thus, it can be concluded that the present developed polymeric combination resulted in improved bioavailability of MFH with controlled release effect and better therapeutic utilization of drug.

**Keywords:** Box-Behnken Design, Metformin hydrochloride, Microspheres, Nuclear magnetic resonance.

Cervical cancer is a major health concern for women worldwide. Copper nanoparticles (CuNPs) exhibit cytotoxic and ROS-mediated anticancer effects. Natural compounds like curcumin, ferulic acid, and gallic acid have antioxidant, anti-inflammatory, and anticancer properties but limited bioavailability. Combining these compounds with CuNPs enhances stability, cellular uptake, and synergistic anticancer activity, offering a promising approach for cervical cancer therapy. Aim & Objectives: To synthesize and characterize CuNPs stabilized with curcumin and ferulic/gallic acid. To evaluate their cytotoxic and apoptotic effects on cervical cancer cells.To study the role of oxidative stress and ROS in anticancer activity.To compare the synergistic efficacy of the combined system with individual agents. Methodology:Synthesis & Characterization: Prepare copper nanoparticles using curcumin and ferulic/gallic acid as reducing/stabilizing agents.Characterize by UV–Vis, DLS, TEM, FTIR, and XRD for size, stability, and binding. Cell Culture: Use cervical cancer cell lines (HeLa/SiHa) and normal cells as control. In-vitro Evaluation: Assess cytotoxicity (MTT/Resazurin assay) and calculate $IC_{50}$.Study ROS generation, apoptosis (Annexin V/PI), and cell cycle arrest.Check expression of apoptotic markers (Bax, Bcl-2, Caspase-3). Data Analysis: Compare activity of CuNPs, curcumin, ferulic/gallic acid, and their combinations.Use statistical analysis (ANOVA, $p<0.05$). Results & Conclusion: CuNPs with curcumin and ferulic/gallic acid were stable and nanosized.Showed higher cytotoxicity, ROS generation, and apoptosis in cervical cancer cells than individual agents. The combination of CuNPs with curcumin and ferulic/gallic acid enhances anticancer activity through oxidative stress and apoptosis, making it a promising approach for cervical cancer therapy.

**Keywords:** Copper nanoparticles, Curcumin, Ferulic/Gallic acid, Cervical cancer, Apoptosis

**SURFACE-FUNCTIONALIZED COPPER NANOPARTICLES WITH CURCUMIN AND GALLIC ACID FOR FERROPTOSIS-INDUCED THERAPY IN TRIPLE-NEGATIVE BREAST CANCER: A DEEP-LEARNING GUIDED PHARMACEUTICAL APPROACH**

Katreddy Balu and M.Ramayyappa*
Department of Pharmaceutical Analysis- Shri Vishnu College of Pharmacy, Vishnupur, Bhimavaram, Andhra Pradesh, India, 534202
balukatreddy369@gmail.com

Triple-negative breast cancer (TNBC) is a highly aggressive subtype of breast cancer lacking hormone receptors and HER2 expression, making it unresponsive to conventional targeted therapies. Ferroptosis, a regulated form of cell death characterized by iron/copper-dependent lipid peroxidation, has emerged as a promising therapeutic approach. Copper nanoparticles (CuNPs), owing to their intrinsic redox activity, can trigger ferroptosis via Fenton-like reactions. Functionalization with phytochemicals such as curcumin and gallic/ferulic acid enhances nanoparticle stability, provides synergistic antioxidant–prooxidant activity, and promotes tumor-specific targeting. This project aims to develop and evaluate surface-functionalized CuNPs with curcumin and gallic/ferulic acid for ferroptosis-mediated TNBC therapy. Objectives include: (i) synthesis and characterization of CuNP–phytochemical conjugates via green chemistry, (ii) AI-based modeling to predict nanoparticle–protein interactions and optimize pharmacokinetic properties, and (iii) in vitro and in vivo evaluation of ferroptosis induction, efficacy, and safety. CuNPs will be synthesized using a green chemistry approach employing phytochemical extracts as reducing and stabilizing agents. Structural and morphological characterization will be performed using UV–Vis, FTIR, XRD, SEM/TEM, and DLS techniques. Deep-learning algorithms will model nanoparticle–protein interactions and predict ADMET profiles. In vitro studies on TNBC cell lines will evaluate lipid ROS accumulation, glutathione depletion, GPX4 inhibition, and ferroptotic markers. In vivo efficacy and biosafety will be assessed in TNBC xenograft mouse models. CuNP–phytochemical nanoconjugates are anticipated to demonstrate enhanced stability, selective tumor targeting, and robust ferroptotic activity, leading to significant tumor regression with reduced systemic toxicity. This study highlights a green nanotechnology and AI-integrated pharmaceutical strategy for TNBC therapy.

**Keywords:** Copper nanoparticles; Curcumin; Gallic acid; Ferroptosis; Triple-negative breast cancer.

**ANTIMICROBIAL STUDIES OF SECRETED PROTEASE OR PROTEIN OF LACTIC ACID BACTERIA ISOLATED FROM INDUSTRIAL WASTE WATER**

Ch. Keerthi Sowjanya*, keerthizz890@gmail.com, Vinod Kumar. R,
Department of Pharmaceutics, Shri Vishnu College of Pharmacy, Bhimavaram,534202
vinoddhniper@gmail.com

The first study on lactic acid bacteria was published in 1905 by P. A. Levane on "Proteose Cleavage Products". Lactic acid bacteria (LAB) are gram-positive bacteria that produce lactic acid. Novel enzymes and antibacterial chemicals were always investigated from LABs of various origins, including fermented foods, dairy products, and so on, due to their non-pathogenic nature, presence in the gastrointestinal tract (GIT), and antimicrobial effects. LAB are also Generally Recognized As Safe (GRAS) and used as probiotics in humans. Isolation and antimicrobial efficacy of LAB from industrial waste water has not been done extensively. The present work focuses on the antimicrobial effects of secreted proteins on coli and S. aureus. Co-culture of CFS at pH 5.5 with bacteria showed killing of bacteria. Primary LC-MS analysis reveals that the secreted protein contains AraC peptidproteases isolated from industrial waste water. Isolation of LAB was done on Demann Rogosa sharp (MRS) agar at pH 5.5-7.0 and characterized by a catalase test, acid production test, and antibiotic susceptibility profile. The isolated LAB was at pH 5.5 and was found to be resistant to Nalidixic acid, colistin, cefepime, mecillinam, and cefepime. Cell free supernatant (CFS) showed a zone of inhibition on skim milk agar, providing evidence for secreted protease from LAB. Secreted protease profiles were identified on SDS PAGE with bands of 116-200 KDa. Cell free supernatant showed antibacterial activity in a dose-dependent manner. This data supports the hypothesis that LAB isolated from industrial waste water can have an antimicrobial effect with future applications.

**ATTENUATION OF ORANGE YELLOW S- INDUCED ANXIETY IN MICE BY VERNONIA CINEREA: A REDOX MODULATORY APPROACH.**

Kiruthika Balamurugan and Navaneetha Krishnan Subramaniyan
Department of Pharmacology, Dr. Kalam College of Pharmacy, Avanam, Thanjavur (Dt.,) Tamilnadu- 614623
kiruthika999000v@gmail.com

In current research, orange yellow S is a synthetic azo dye widely used in the food and pharmaceutical industries, has been associated with neurobehavioral disturbances upon prolonged exposure. The objective of this research to evaluate the anxiolytic and antioxidant potential of vernonia cinerea in a murine model of anxiety induced by orange yellow S. An experimental anxiety model was established in mice by orally administering orange yellow S at 20mg/kg for 30 consecutive days. To assess the protective effects, the ethanol extract of vernonia cinerea (EEVC) was administered at 400mg/kg orally, one hour after dye exposure. Diazepam (1mg/kg) served as the standard anxiolytic control. Behavioral assessments were performed to evaluate anxiogenic responses. Treatment with vernonia cinerea significantly improved anxiety like behavior in dye exposed mice, with effects comparable to those observed in the diazepam group. Biochemical analysis revealed a significant increase in brain antioxidant enzymes, including Catalyze (CAT) & Superoxide Dismutase (SOD), as well as elevated Gamma- amino butyric acid (GABA) levels. Histopathological examination of the hippocampal CA3 region showed that EEVC reduced structural abnormalities such as perivascular edema, hemorrhage & neuronal degeneration. Therefore vernonia cinerea extract effectively attenuates orange yellow S – induced anxiogenic behavior in mice by restoring oxidative balance and modulating neurotransmitter levels.

**Keywords:** Hippocampal CA3, Orange yellow S, anxiety behavior.

**RX FOR A CLEANER PLANET: SMART STRATEGIES FOR WASTE MANAGEMENT**

ISBN: 978-81-980623-8-3

Himaja Kasturi, K. Venkateswara Raju, S. Annapurna, Lakshmi Prasanthi Nori
Department of Regulatory affairs, Shri Vishnu College of Pharmacy, Bhimavaram, West Godavari (Dt), Andhra Pradesh, India.
venkateswararaju.k@svcp.edu.in

Pharmaceutical waste presents serious risks to the environment and public health, necessitating effective management strategies. Improper disposal can lead to contamination of water bodies, soil, and the emergence of antibiotic-resistant bacteria, which complicates treatment options. To combat these issues, adherence to regulatory guidelines from agencies like the EPA and DEA is essential for minimizing environmental impacts. Public education is critical for ensuring proper medication disposal, helping to raise awareness of disposal methods and their importance. A multifaceted approach that includes comprehensive waste management plans, legal compliance, and public education can significantly mitigate the risks associated with pharmaceutical waste. By implementing these strategies, we can protect public health and the environment from the harms of improper pharmaceutical disposal.

## FORMULATION AND EVALUATION OF CURCUMIN NANOEMULGEL FOR BURN WOUND HEALING: A RAT MODEL APPROACH

Roli Agrawal, Parag Jain,
Rungta College Of Pharmaceutical Sciences and Research, Kohka Kurud Road, Bhilai, INDIA – 490023
Department Of Pharmacy, Rungta International Skill University, Kohka Kurud Road, Bhilai, INDIA – 490023
roliagrawal2216@gmail.com

Burn wounds present a significant clinical challenge due to delayed healing, risk of infection, and excessive inflammation. Curcumin, a polyphenolic compound derived from Curcuma longa, exhibits potent anti-inflammatory, antioxidant, and antimicrobial properties but suffers from poor aqueous solubility and bioavailability. This study investigates the therapeutic efficacy of a topically applied curcumin-loaded nanoemulgel formulation in accelerating burn wound healing in Wistar rats. A standardized second-degree burn model was induced on the dorsal surface of rats, followed by daily topical application of curcumin nanoemulgel (1% w/w) for 21 days. The formulation was characterized for droplet size, zeta potential, rheological behaviour, and drug release kinetics. Wound contraction rate, epithelialization period, histopathological analysis, and biochemical markers (hydroxyproline content, catalase, superoxide dismutase, and malondialdehyde levels) were assessed to evaluate healing progression. Results demonstrated significantly enhanced wound contraction, reduced epithelialization time, and improved collagen deposition in the curcumin nanoemulgel-treated group compared to control and placebo groups. Histological examination revealed accelerated granulation tissue formation, neovascularization, and re-epithelialization. Biochemical assays confirmed modulation of oxidative stress and inflammatory mediators, supporting the mechanistic role of curcumin in tissue regeneration. In conclusion, the curcumin nanoemulgel exhibited superior burn wound healing activity, attributed to its enhanced dermal penetration, sustained release, and synergistic pharmacological effects. This nanoformulation holds promise as a translational therapeutic strategy for topical management of burn injuries.

**Keywords:** – Epithelialization Period, nanoemulgel, neovascularization.

## FORMULATION AND EVALUATION OF RAPIDLY DISINTEGRATING TABLETS OF DILTIAZEM HCl

M Nassefa*, M Mohan Sai, M Mohan Varma
Department of Pharmaceutics, Shri Vishnu College of Pharmacy, Vishnupur, Bhimavaram, West Godavari (Dist) 534202, Andhra Pradesh, INDIA.
123058@svcp.edu.in

Rapidly disintegrating tablets, also known as orally disintegrating tablets (ODTs) are solid unit dosage forms, which disintegrate or dissolve rapidly in the mouth without chewing and water. The orally disintegrating tablets provide an advantage particularly for pediatric and geriatric populations who have difficulty in swallowing conventional tablets and capsules. Diltiazem HCl is an anti-hypertensive drug. The ODTs of Diltiazem HCl can achieve fast onset of action for treating Hypertension. The present study focuses on the formulation and evaluation of Diltiazem HCl rapidly disintegrating tablets using both natural and synthetic superdisintegrants, including Sodium Starch Glycolate, Croscarmellose Sodium, Guar Gum, and ground banana flour. Tablets were prepared via dry granulation, and other excipients such as Lactose, Magnesium Stearate, and Talc were incorporated. Eight formulations (F1–F8) were developed and subjected to pre-compression (bulk density, tapped density, angle of repose, Hausner's ratio) and post-compression (hardness, friability, drug content, water absorption ratio, wetting time, dissolution, and disintegration time) evaluations. All parameters met the acceptable limits prescribed by the Indian Pharmacopoeia (IP). Among all formulations, F2 exhibited the shortest disintegration time of 28 seconds and the highest drug release of 98% within 30 minutes. Drug release kinetics indicated that F2 followed first-order kinetics.The Differential Scanning Calorimetry (DSC) was used to evaluate the drug – excipient interaction. The DSC studies revealed the absence of drug-excipient interaction in the F2 formulation.The results demonstrate that natural superdisintegrant like ground banana flour can be effectively used in combination with synthetic agents to formulate efficient ODTs of Diltiazem HCl.

**Keywords:** Diltiazem HCl, Disintegration, Dissolution, Superdisintegrants.

## FORMULATION AND EVALUATION OF POLYVINYL ALCOHOL BASED ORAL THIN FILM OF APIXABAN

Yamini Thakur, Mohammad Adnan Raza, Ajazuddin
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023
yaminithakur218@gmail.com

The current research work aimed to prepare an optimized and evaluate fast-dissolving oral thin film of Apixaban using polyvinyl alcohol as a film former. The oral thin film of Apixaban enhances the solubility, bioavailability, and therapeutic efficacy in thrombus, pulmonary embolism, and venous thromboembolism. The chemical compatibility and thermal analysis were investigated with the help of FTIR, and DSC. The optimization was performed with the Box-Behnken design. The concentrations of film former (PVA: X1), plasticizer (PEG 200: X2), and super disintegrant (cross povidone: X3) were considered as independent factors and the critical quality attributes for the oral films are disintegration time, dissolution, and folding endurance. The ANOVA comprised of Quadratic model which predicted p-values of 0.0039, 0.0105, and 0.0020 significant. The scanning electron microscopy assessed the texture of the film. An optimized batch P6 disintegrated within 19 seconds, released the drug (99.07 %) within 10 min and had a folding endurance of 116. The results conclude that optimized batch P6 of oral thin film of Apixaban significantly minimizes the deep vein thrombosis, pulmonary embolism, and venous thromboembolism due to fastest onset of action and improved solubility. Thus, the complications associated with the clotting of blood is sharply reduces.

**Keywords:** Oral thin film; Apixaban; Polyvinyl alcohol; Deep vein thrombosis; Box-Behnken design.

## ECO-FRIENDLY FABRICATION OF SILVER NANOPARTICLES EMPLOYING ALPINIA GALANGA EXTRACTS: STRUCTURAL CHARACTERIZATION AND ANTIBACTERIAL ACTIVITY

Pathan Jabeen and V.Rama Rao*
Department of Pharmaceutics, Shri Vishnu College of Pharmacy, Bhimavaram, Andhra Pradesh, India- 534 202
jabeenpathan2004@gmail.com

Introduction: The development of eco-friendly nanomaterials offers a sustainable alternative to conventional antimicrobial agents. Alpinia galanga (greater galangal) contains phytochemicals such as flavonoids, phenolics, and terpenoids that can act as reducing and stabilizing agents for nanoparticle synthesis. Aim: To synthesize and characterize silver nanoparticles (AgNPs) using A. galanga rhizome extract and to evaluate their antibacterial and antibiofilm potential. Objectives: (i) Optimize the

ISBN: 978-81-980623-8-3

biosynthesis of AgNPs using aqueous extract; (ii) characterize particles using UV–Vis, FTIR, XRD, SEM/TEM, and EDX; (iii) evaluate antibacterial activity against Staphylococcus aureus and Escherichia coli; (iv) assess antibiofilm and stability compared with crude extract. Methodology: Fresh rhizomes were extracted in distilled water and mixed with 1 mM $AgNO_3$ solution. Nanoparticle formation was monitored by UV–Vis spectroscopy. Structural and surface analyses were carried out using FTIR, while XRD confirmed crystallinity. Morphological features were determined by SEM/TEM, and elemental composition by EDX. Antibacterial activity was assessed using agar well diffusion, MIC determination, and biofilm inhibition assays. Stability of AgNPs was monitored during storage. Results: Rapid reduction of $Ag^+$ to $Ag^0$ occurred, producing spherical AgNPs (15–40 nm) with a distinct SPR peak (~430 nm). FTIR confirmed phytochemical involvement; XRD indicated face-centered cubic silver, and EDX validated elemental silver. The AgNPs exhibited strong antibacterial activity and significant biofilm reduction, outperforming crude extract, and remained colloidally stable.Conclusion: A. galanga-mediated AgNPs represent a sustainable and effective antimicrobial platform with potential biomedical applications.

## EXPLORING THE CYTOTOXICITY OF HEXABUTYLOXYTRIPHENYLENE, A DISCOTIC LIQUID CRYSTAL: IMPLICATIONS FOR MEDICAL APPLICATIONS

Kumudha S M and Dr. Yogesh H S
Department of Pharmacology, Nitte College of Pharmaceutical Sciences, Yelahanka, Bengaluru -560064
Kumudhaacharya341@gmail.com

The three cell lines 3T3L1, THP-1, and L929 were subjected to the cytotoxicity of hexabutyloxytriphenylene, a well-known triphenylene discotic liquid crystal (DLC). DLCs are widely used in various technologies, but little is known about their pharmacological characteristics, including cytotoxicity. Hexabutyloxytriphenylene (HAT-4) was the test material, and the MTT assay was used to measure concentrations ranging from 1.9 to 1000 µM. Cell viability was assessed after three cell lines—3T3L1, THP-1, and L929—were treated with different dosages of HAT-4 for 24, 48, and 72 hours. Statistical analysis was performed using One-way ANOVA followed by Tukey's post hoc test. Hexabutyloxytriphenylene demonstrated concentration-dependent cytotoxicity in all tested cell lines. The MTT assay showed variable reductions in cell viability depending on concentration and exposure duration. These findings highlight the importance of evaluating pharmacological characteristics of DLCs, particularly their potential effects on diverse cell types. The triphenylene DLC hexabutyloxytriphenylene, despite being frequently studied, exhibited significant cytotoxic effects on 3T3L1, THP-1, and L929 cells. By emphasizing the need to understand DLC cytotoxicity and their pharmacological properties, this study addresses an important research gap with implications for future biomedical applications. This work enhances current understanding of the cytotoxicity of hexabutyloxytriphenylene and lays the groundwork for exploring pharmacological features of DLCs. The findings highlight the potential role of liquid crystals in medicine and suggest directions for developing novel, targeted therapeutic strategies.

**Keywords:** Discotic Liquid Crystals, Cytotoxicity, Drug Delivery, Medical Applications, Hexabutyloxytriphenylene

**PC-24**

## DEVELOPMENT AND CHARACTERIZATION OF A HERBAL ANTIMICROBIAL CREAM: A SYNERGISTIC APPROACH USING CURCUMIN AND GLYCYRRHIZIN

Vedant Kamlakar Shaligram[1], Madhuri U Shelar[1], Nutan V Nibe[2]
[1]Department of Pharmaceutical Quality Assurance, Alard School of Pharmacy, Pune – 411057, India
[2]Department of Pharmaceutical Chemistry, Trinity College of Pharmacy, Pune – 411048, India
shaligramvedant8@gmail.com

In the present study, a herbal antimicrobial cream was developed using ethanolic extracts of Curcuma longa (curcumin) and Glycyrrhiza glabra (glycyrrhizin), combined with excipients, including sesame oil containing sesamin and coconut oil containing lauric acid, to improve formulation stability, spreadability, and dermal absorption. The objective was to utilize the therapeutic potential of herbal active constituents and also enhancing the functional roles of other formulation components for topical application, which focuses on achieving effective antimicrobial activity. The cream was prepared via standard emulsification techniques and evaluated for physicochemical parameters including pH, spreadability, viscosity, and skin irritation, as well as antimicrobial efficacy against Escherichia coli, Staphylococcus aureus, and Candida albicans. The optimized batch exhibited a pH of 6.8, spreadability of 9.33 g·cm/sec, and no signs of irritation in patch testing. Antimicrobial activity was confirmed by zones of inhibition measuring 20 mm for E. coli, 18 mm for S. aureus, and 15 mm for C. albicans, indicating broad-spectrum efficacy. Franz diffusion studies showed that curcumin and glycyrrhizin were able to pass through biological membranes, suggesting the cream can effectively deliver its active ingredients. The formulation showed no signs of phase separation or degradation over a brief period of time, remaining physically stable. This approach demonstrates that integrating herbal extracts with excipients can result in a safe, effective, and industrially viable topical antimicrobial product.

**Keywords:** Curcumin, Glycyrrhizin, formulation, antimicrobial cream, topical delivery.

## DESIGN AND IN-SILICO DEVELOPMENT OF CURCUMIN-BRIDGED GALLIC ACID AS AN ANTICANCER AGENT

Bokka Sahasra, Sujit Kumar Mohanty
Department of Pharmaceutical Chemistry, Shri Vishnu College of Pharmacy, Bhimavaram, West Godavari Dt. India-534202.
bsahasra244@gmail.com

Curcumin and ferulic acid are natural polyphenolic compounds known for their antioxidant, anti-inflammatory, and anticancer properties; however, both suffer from poor stability, rapid metabolism, and limited bioavailability, which restrict their clinical application. In this study, we designed and evaluated novel curcumin-bridged ferulic acid (CBFA) conjugates using a comprehensive in-silico approach to enhance therapeutic efficacy. A small library of mono- and bis-conjugates was generated employing ester, carbonate, and PEG-based linkers, followed by optimization and physicochemical profiling. Molecular docking against multiple cancer-associated targets, including COX-2, Keap1–Nrf2, tubulin, and Bcl-2, demonstrated strong binding affinities and favorable interaction networks compared with parent compounds. Molecular dynamics simulations confirmed the stability of the top docked complexes over 100 ns trajectories, with consistent hydrogen bonding and low RMSD fluctuations. ADMET predictions suggested improved oral bioavailability, favorable pharmacokinetic parameters, and minimal toxicity risks. Among the designed analogs, PEG-linked and carbonate-bridged conjugates showed the most promising balance of stability, activity, and drug-likeness. These results highlight CBFA hybrids as potential next-generation anticancer candidates, meriting further experimental synthesis, stability studies, and biological evaluation to validate their therapeutic potential.

**Keywords:** Curcumin, gallic acid, ferulic acid, ADMET, cytotoxicity.

## DESIGN AND IN-SILICO DEVELOPMENT OF CURCUMIN-BRIDGED GALLIC ACID AS AN ANTICANCER AGENT

Shaik.Yasmine, Sujit Kumar Mohanty
Department of Pharmaceutical Chemistry, Shri Vishnu College of Pharmacy, Bhimavaram, West Godavari Dt. India-534202.
yasmineshaik142@gmail.com

Curcumin and gallic acid are well-established natural polyphenols with complementary anticancer activities, but their therapeutic utility is limited by poor bioavailability, instability, and rapid metabolism. To overcome these challenges, we designed and evaluated novel curcumin-bridged gallic acid (CBGA) hybrids using in-silico approaches. A focused library of mono-, bis-, and bridged conjugates was constructed through ester, carbonate, and short PEG linkers, followed by physicochemical and drug-likeness profiling. Molecular docking against key oncogenic targets, including Keap1–Nrf2, COX-2, tubulin, and Bcl-2, revealed favorable binding energies and interaction patterns compared with parent molecules. Top candidates were further validated using molecular

ISBN: 978-81-980623-8-3

dynamics simulations, which demonstrated stable protein–ligand complexes and consistent hydrogen bonding over 100 ns trajectories. In-silico ADMET screening predicted acceptable oral bioavailability, low cardiotoxicity, and reduced PAINS alerts for optimized derivatives. The bis-gallate carbonate and PEG-linked conjugates showed the best balance of stability, affinity, and drug-likeness. These findings suggest that CBGA hybrids may serve as promising next-generation anticancer leads by integrating the pharmacophoric features of curcumin and gallic acid into a single molecular scaffold. Experimental synthesis, stability evaluation, and cytotoxicity assays are warranted to validate the computational predictions.

**Keywords:** Insilico, polyphenols, ADMET, cytotoxicity.

## DEVELOPMENT AND OPTIMIZATION OF A MICROEMULSION FOR ERLOTINIB HYDROCHLORIDE: A NOVEL APPROACH FOR ENHANCED LUNG CANCER THERAPY

Firdos Sultana
Varadaraja Institute of Pharmaceutical Education and Research
Jayanagara South, Shettihalli Ring Road, Tumkur
fidossultana.007@gmail.com

This paper is devoted to the design, development, and optimization of microemulsion-based nasal spray formulation of erlotinib hydrochloride, a targeted anticancer drug. Solubility studies, as well as partition coefficient (log p) and drug-excipient compatibility studies were also performed to identify the most appropriate excipient combination to develop a microemulsion. Solubility tests showed that Labrafac, Cremophor RH 40 and Transcutol P were best to improve the solubility of the drug. The partition coefficient was suitable and the lipophilicity of the drug would favor nasal absorption. In addition, the stereochemical study by FTIR and DSC analysis demonstrated that erlotinib hydrochloride could not dissolve at room temperature in the presence of chosen excipients. Optimization of the microemulsion formulation was done using a Pseudoternary phase diagram and investigation of the excipient ratio effects on formulation stability was carried out. It was noted that the phase behaviour evolved between clear and turbid formulations as the surfactant to co-surfactant ratio (Smix) declined. The best formulations of microemulsions were also described as clear, low viscous and stable. To further optimize the formulation, a central composite design (ccd) was employed, and the responses such as that of globule size, zeta potential and polydispersity index were determined. The findings revealed that the smallest globule size, low zeta potential and a low polydispersity index were obtained in run 3 and this was the most stable, and uniform formulation. In summary, the paper has shown the possibility of microemulsion-based nasal delivery of erlotinib hydrochloride which is highly soluble, stable and bioavailable thereby has increased therapeutic responses in the treatment of lung cancer.

donthula.srilatha@gmail.com

The purpose of this research was to develop a novel gastro retentive drug delivery system based on Direct compression method for sustained delivery of active agent. Quick GI transit could result in incomplete drug release from the drug delivery system above the absorption zone leading to decreased efficacy of the administered dose and thus less patient compliance. Gastro retentive floating tablets of Famotidine HCL were prepared direct compression method using different polymers with different concentrations of HPMC K4M, HPMC K100 M and Carbopol 940. The optimized formulation F5 exhibited 99.39% drug release in 12hrs.In vitro drug release kinetics was found to follow both zero order and the possible mechanism of Famotidine HCL. The optimized formulation F5 showed good result in pre compression and post compression parameters as per IP.

**Keywords:** Famotidine HCL, HPMC K4M, HPMC K100 M and Carbopol 940.

## DEVELOPMENT AND EVALUATION OF LUTEOLIN LOADED TEMPERATURE SENSITIVE IN-SITU GEL

Payal S Yadav, P. N. Bhujadi, A. R. Pawar
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist-Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
payalsy515@gmail.com

This study aimed to design and enhance a temperature-responsive In-Situ gel infused with luteolin to facilitate better delivery for acute wound healing. A In-Situ gel that is responsive to temperature changes was developed using PNIPAM and Poloxamer 188 as thermosensitive polymers, employing a structured $3^2$ factorial design. Nine formulations were created, with PNIPAM concentrations ranging from to 10-20% w/v and Poloxamer 188 from to 1-5% w/v. These formulations were evaluated for physical appearance, pH, gelation temperature, gelation time, viscosity, mucoadhesive strength, drug content, and ex vivo permeation through the mucosa. All formulations had pH levels ranging from 5.7 to 6.3, making them suitable for delivery, and displayed excellent uniformity in drug content, between 97.5% and 99.2%. The gelation temperature was found to have a quadratic correlation with polymer concentrations, varying from 27.2°C to 36.8°C, while mucoadhesive strength showed a linear increase, ranging from 3542.7 to 5983.6 dyne/cm2. Formulation F7, was deemed optimal, as it exhibited an ideal gelation temperature of 33.7°C, a mucoadhesive strength of 4896.4 dyne/cm2, and superior ex vivo permeation of 92.8% over 12 h, with the highest flux recorded at 68.3 µg/cm2/h. Statistical validation confirmed that the predictive accuracy was excellent, with a minimal error ranging from 0.12% to 1.04%. The optimized formulation demonstrated strong stability under accelerated conditions, with a projected shelf-life of 2.3 years. Thermosensitive In-Situ gel, optimized for luteolin delivery, presents a promising approach with improved retention and controlled release, potentially enhancing treatment outcomes in acute wounds.

**Keywords:** Luteolin; Temperature-sensitive gel; In-situ gelling system; PNIPAM

**PC-30**

## DESIGN AND EVALUATION OF CONTROLLED RELEASE GASTRIC FLOTING DRUG DELIVERY SYSTEM OF PROTON PUMP INHIBITOR

Dr. K Kavitha, Om Balaji Biradar, Aswini P V
Department of Pharmaceutics, NITTE College of Pharmaceutical Sciences, Govindapura, Yelahanka, Bengaluru – 560064
Obiradar320@gmail.com

This research focuses on the development and evaluation of controlled release gastric floating tablets for pantoprazole sodium, a proton pump inhibitor used to treat gastric and duodenal ulcers. Tablets were prepared using direct compression with microcrystalline cellulose, sodium bicarbonate, citric acid, magnesium stearate, and HPMC K100/K15 as polymers. Physicochemical assessments and compatibility studies (FTIR, DSC) confirmed no interactions between the drug and polymers. Results showed that tablet formulations with HPMC K100 provided better controlled release and extended drug delivery up to 12 hours, compared to HPMC K15. The drug release kinetics followed a Non-Fickian diffusion mechanism, combining matrix erosion and diffusion processes. The floating lag time increased with higher amounts of gas-generating agents, enhancing gastric retention. The study concludes that pantoprazole sodium floating tablets formulated with HPMC K100 offer a promising approach for prolonged gastric retention and improved bioavailability in clinical applications. This optimized system supports better patient compliance due to its extended release profile.

**Keywords:** Pantoprazole sodium, Gastroretentive, Floating drug delivery systems, Release kinetics. Buoyancy studies.

## DEVELOPMENT OF CHITOSAN-BASED BUCCAL PATCHES INCORPORATING HYDROXYAPATITE AND BETANIN FOR PERIODONTAL APPLICATIONS

Sujan Pal, Prithwiraj Karmakar, Sushangar Dey, Asim Halder*
Department of Pharmaceutical Technology, School of Health and Medical Sciences, Adamas University, Kolkata, India-700126
sujanpal122001@gmail.com

Periodontal disease has become one of the greatest threats to oral health requiring multifaceted therapies. This study describes the

ISBN: 978-81-980623-8-3

preparation of a new mucoadhesive buccal patch made of chitosan, hydroxyapatite (HA) from eggshells and, betanin for periodontal use. Chitosan is a biodegradable and biocompatible polymer with great localized delivery characteristics. Hydroxyapatite closely resembles tooth enamel's mineral composition helping remineralization and restore dental tissue. Betanin provides antioxidant, anti-inflammatory, and antimicrobial effects with low toxicity. Hydroxyapatite was made by calorically treating eggshell powder at controlled conditions. The buccal patch was made by mixing chitosan and polyvinyl alcohol solutions and casting the patch with solvent evaporation method. Characterization of the buccal patch showed good physio-chemical properties including suitable thickness, good folding endurance, suitable moisture content and surface pH of 6.85 ± 0.2. The patch illustrated strong antioxidant activity with 64.6% inhibition in a DPPH assay and showed ex-vivo mucoadhesion time of 50 - 60 minutes on porcine dermal tissue. Swelling index and mechanical strength characteristics also support clinical use. These findings highlight the promise of the chitosan-hydroxyapatite-betanin buccal patch as a viable, non-invasive means of drug delivery for periodontal treatment, that provided sustained, localized therapeutic delivery and increased patient compliance. This formulation could be a promising alternative to traditional treatment for periodontal disease and post-dental surgical conditions.

**Keywords:** Chitosan, Hydroxyapatite, Betanin, Buccal patch, Periodontal diseases

## DESIGN AND CHARACTERIZATION OF FLOATING TABLETS OF METAPROLOL TARTARATE

Shaik Tafazzul and V.Saikishore
Department of Pharmaceutics,Bapatla College of Pharmacy, Bapatla-522101
tafazzulshaik23@gmail.com

The aim of present research work is to formulate and evaluate controlled release floating tablet of Metaprolol Tartarate in view to enhance bioavailability and therapeutic action. The tablets were formulated by employing Moringa oleifera, gum kondagogu, Karaya gum. The powder blend was evaluated for flow properties. All the formulations showed values within the prescribed limits for tests like hardness, friability and weight variation which indicate that the prepared tablets are of standard quality. All the tablets were formulated using sodium bicarbonate as effervescent agent. All the prepared formulations floated immediately after placing into the beaker and the floating was maintained more than 14 hrs. It was observed that the carbon dioxide generated from sodium bicarbonate in presence of dissolution medium (0.1N HCL) was trapped in the polymer gel matrix formed by the hydration of polymer which decreases the density (<1) and makes the tablet buoyant. The correlation coefficient values (r) revealed that the dissolution profiles followed Zero order kinetics and the mechanism of drug release was governed by Peppas model. The n values are found to be more than 0.5 (n>0.5) indicted that the drug release was predominantly controlled by non fickian diffusion. Based on the release rate constant and % of drug release the formulations prepared with Moringa oleifera gum shown prolonged retarding nature compared with the formulations. Among all the formulations, formulation containing drug and Moringa oleifera gum in 1:1.5 ratio was found to be optimized formulation

**Keywords:** Metaprolol Tartarate, Moringa oleifera, Gum kondagogu, Karaya gum

**PC-33**

## DEVELOPMENT OF A DUAL-ACTION FACE MASK TARGETING BLEMISH CONTROL AND ANTI-AGING FOR HOLISTIC SKIN CARE

Alana Antony, Nidhin B, Mrs. Rasmy T.K
Department of Pharmaceutics- NITTE College of pharmaceutical sciences, NITTE Deemed To Be University, Bangalore, India
Department of Pharmaceutics, Sanjo College of Pharmaceutical Studies, Vellapara,
Kuzhalmannam Palakkad 678702, Kerala
alanaantony522002@gmail.com

Face masks are increasingly recognized for their multifunctional benefits in skin care. The objective of this study was to formulate a face sheet mask that provides dual anti-blemish and anti-aging effects, thereby rejuvenating the skin. The formulation incorporated benzoyl peroxide (antimicrobial and keratolytic agent) and orange oil (antioxidant and skin-brightening) as active components. A flexible film was achieved using gelatin as the gelling agent, with starch as a thickener and liquid paraffin as an emollient to maintain hydration and reduce irritancy associated with benzoyl peroxide.Physicochemical characterization included organoleptic assessment, thickness, folding endurance, moisture content, and in-vitro drug release. Franz diffusion cell studies demonstrated uniform and sustained drug release, quantified by UV spectroscopy. The optimized film showed appropriate flexibility, good adherence to skin surface. Moisture analysis confirmed adequate hydration, while sensory evaluation indicated a smooth, non-greasy finish. Functionally, the formulation showed marked potential in reducing blemishes and delaying early signs of aging, attributed to synergistic antimicrobial, antioxidant, and keratolytic effects. Safety tests confirmed cosmetic acceptability with minimal irritation risk.In conclusion, this dual-action face mask provides an effective, consumer-friendly approach to managing acne-related blemishes and premature skin aging, representing a promising candidate for sustainable cosmeceutical development.

**Keywords:** Rejuvenation, gelatin, starch, benzoyl peroxide, starch.

## FORMULATION AND CHARACTERIZATION OF ARTEMETHER NANOEMULSIONS- ADVANCING ANTIMALARIAL THERAPY THROUGH OPTIMIZED NANOCARRIER SYSTEMS.

Srivarshini, Dr. Raman Sureshkumar and N.Venuka Devi
Department of Pharmaceutics- NITTE College of pharmaceutical sciences, NITTE Deemed To Be University,Bangalore, India.
Department of Pharmaceutics, JSS College of Pharmacy, Rocklands, Udhagamandalam-643001 Tamil Nadu, India.
ksrivarshini07072002@gmail.com

Nanoemulsions (NEs) are advanced colloidal drug delivery systems consisting of two immiscible liquids (commonly oil and water) stabilized by surfactants, with droplet sizes ranging from 20–200 nm. Their physicochemical advantages—optical clarity, large surface area, and high kinetic stability against sedimentation and coalescence have made them attractive in pharmaceutical formulations.The choice of formulation components is crucial, particularly the oil phase for solubilizing the active pharmaceutical ingredient (API). A solubility screening study with Artemether, an antimalarial drug, identified castor oil as the most suitable oil, providing the highest solubility (1.1 ± 0.09 mg/mL) due to its lipophilic character and molecular compatibility. surfactant system is very much important in the formulation. Non-ionic surfactants such as the Tween series, Cremophor EL, and Labrasol are favored for their biocompatibility, low irritation, and stability across physiological pH. Miscibility studies revealed Cremophor EL as the best surfactant for castor oil-based systems, offering strong interfacial activity. To lower surfactant concentration and minimize toxicity, co-surfactants including ethanol, isopropyl alcohol, and PEG 600 were assessed. Pseudo-ternary phase diagrams demonstrated that PEG 600 provided the broadest NE region, indicating superior stability. Optimization of the surfactant-to-co-surfactant ratio (Smix) identified 1:5 (Cremophor EL:PEG 600) as optimal, producing smaller droplets, reduced interfacial tension, and excellent thermodynamic stability. This formulation withstood rigorous stress tests, including thermal cycling, centrifugation, and freeze-thaw studies

**Keywords:** Artemether, nanoemulsion, castor oil, Cremophor EL, PEG 600, Smix ratio, Ostwald ripening.

## DEVELOPMENT AND PHYSICOCHEMICAL CHARACTERIZATION OF A FACE SCRUB CREAM CONTAINING ALMOND SHELL POWDER.

Anpitha, S. Deepthi and N. Venuka Devi
Department of Pharmaceutics- NITTE College of Pharmaceutical sciences, NITTE Deemed To Be University, Bangalore, India.
Anpithaej16@gmail.com

Agro-waste valorization provides eco-friendly alternatives to synthetic microbeads in cosmetics. Almond shells, an abundant nut industry by-product, contain a rigid lignocellulosic matrix with phenolic compounds that offer abrasivity and antioxidant potential. When standardized to controlled particle sizes, they can serve as biodegradable exfoliants with added cosmeceutical benefits. In this study, almond shells were cleaned, oven-dried, milled, and sieved (150–300 µm). Characterization included

ISBN: 978-81-980623-8-3

FTIR, SEM, and optical microscopy. The particles were incorporated into a humectant-rich oil-in-water base with glycerol and cucumber extract. The cream was evaluated for pH, moisture/LOD, viscosity, spreadability, microbial quality, and heavy-metal content. Antioxidant activity (DPPH), tyrosinase inhibition, and in-vitro release using a Franz diffusion cell were also assessed. The optimized cream exhibited skin-compatible pH, low residual moisture, and rheology supportive of uniform suspension and rinsability. FTIR confirmed lignocellulosic structures, while SEM and microscopy revealed irregular but non-splintered particles with a narrow size range. Almond shell particles (~150–250 µm) achieved effective exfoliation without micro-abrasions, comparable to walnut and apricot kernel scrubs. Humectants reduced post-exfoliation dryness. Microbial and heavy-metal evaluations met cosmetic safety norms. Antioxidant and tyrosinase inhibition assays indicated phenolic constituents contributed to ROS scavenging and melanogenesis modulation. This standardized almond shellbased scrub cream demonstrated safety, efficacy, and sustainability, representing a scalable biodegradable alternative to synthetic microbeads with potential for consumer and clinical use.

**Keywords:** Almond shell powder, Natural exfoliant, Agro-waste valorization, Antioxidant activity, Tyrosinase inhibition.

## FORMULATION AND EVALUATION OF POLYHERBAL CREAM FOR THE TREATMENT OF ATOPIC DERMATITIS

Suman Gehlot and Satyaendra Shrivastava
Parijat College of Pharmacy, Indore, Madhya Pradesh, India
sumangehlot81@gmail.com

Atopic dermatitis (AD) is a chronic, relapsing inflammatory skin disorder characterized by erythema, itching, dryness, and barrier dysfunction. Conventional therapy often relies on corticosteroids and immunomodulators, which, though effective, are associated with side effects upon prolonged use. Herbal medicines provide a safer alternative due to their multifaceted pharmacological activities and better patient compliance. The present study was undertaken to formulate and evaluate a polyherbal cream containing standardized extracts of Aloe vera, Glycyrrhiza glabra, Azadirachta indica, Curcuma longa, and Avena sativa, selected for their complementary anti-inflammatory and antimicrobialactivity. An oil-in-water emulsion base was prepared using emulsifying wax, paraffin, and shea butter, with humectants such as glycerin to enhance hydration. The cream was evaluated for organoleptic characteristics, pH, spreadability, viscosity, extrudability, stability under accelerated conditions, and microbial quality. Bioactivity screening demonstrated significant anti-inflammatory activity through membrane stabilization assays, along with appreciable antimicrobial potential. The prepared formulation was stable, exhibited acceptable physicochemical parameters, and was free from microbial contamination. Preliminary skin compatibility studies revealed no signs of irritation, indicating its safety for topical application. The findings suggest that the developed polyherbal cream has potential as a safe and effective topical formulation for the management of atopic dermatitis, offering a steroid-sparing alternative.

## NANOMATRIX INTEGRATED MUCOADHESIVE THERMOREVERSIBLE IN SITU NASAL GEL FOR PARKINSONISM

Inchara D, Devi Sneha M, V Kusum Devi
Nitte College of Pharmaceutical Sciences, Nitte deemed to be university, P. B. No.6429, Yelahanka, Bengaluru – 560064
incharadinchara@gmail.com

Parkinson's disease (PD) is a chronic, progressive neurodegenerative condition resulting from the loss of dopamine-producing neurons in the substantia Nigra. The present study highlights the potential of Ropinirole hydrochloride solid lipid nanoparticles (SLNs) incorporated into a nasal in situ gel to overcome poor bioavailability and extensive first pass metabolism associated with conventional therapy. SLNs were prepared by double emulsion technique using glyceryl monostearate, stearyl amine, soya lecithin, Tween 80 and characterized for morphology, stability and entrapment efficiency. TEM confirmed spherical nanoparticles in the nanometre range, while zeta potential analysis indicated good stability. Entrapment efficiency ranged from 42.41–72.42%, highest at the 80:20 GMS: lecithin ratio. In vitro studies revealed an initial burst followed by sustained release, with FSN3 showing 80.3 ± 1.2% release at 12 h. Based on entrapment and release, FSN2, FSN3, and FSN6 were chosen for gel formulation. Thermosensitive in situ gels were formulated with poloxamer 407 and HPMC K4M, where SG1showed optimal sol to gel transition, rapid gelation, and strong mucoadhesion. In vitro release of SG1 achieved 73.85% drug release in 12hrs, while ex vivo nasal mucosa studies demonstrated 81.26% release following near zero order kinetics with diffusion-controlled mechanism. The optimized formulation successfully enhanced permeation, sustained drug release and bypassed first-pass metabolism, indicating improved bioavailability and patient compliance. Thus, Ropinirole hydrochloride SLN loaded intranasal in situ gel offers a promising alternative to oral therapy for effective management of Parkinson's disease.

**Keywords:** In situ gel, Parkinson's disease, SLN, Poloxamer 407, HPMC K4M

## INJECTABLE SMART HYDROGEL DEPOT FOR PERPETUAL CORTICOSTEROID RELEASE IN ARTHRITIC THERAPY

Kaviyarasi M, V Kusum Devi, Devi Sneha M
NITTE College of Pharmaceutical Sciences, Nitte deemed to be university, P. B. No.6429, Yelahanka, Bengaluru - 560064
kaviyarasi2001@gmail.com

Osteoarthritis is a prevalent chronic degenerative disorder characterized by pain, inflammation and impaired joint mobility. It is commonly managed with oral analgesics or NSAIDs; however, these therapies are limited by systemic adverse effects and inadequate drug levels at the site of action. intraarticular injections allow localized drug delivery with reduced systemic exposure, but rapid efflux from the synovial cavity limits their efficacy. Sustained-release formulations using biodegradable polymers offer a promising alternative for prolonged therapeutic action. In this study, betamethasone dipropionate (BTM) nanoparticles were formulated using the emulsion solvent evaporation method with PLGA and PCL polymers to minimize burst release and enhance drug retention. The nanoparticles were evaluated for drug-polymer compatibility, particle size, shape, entrapment efficiency, surface charge (zeta potential) and thermal stability. FTIR and DSC analyses confirmed the absence of drug-polymer interactions. The optimized formulation (drug: polymer 1:3; PLGA: PCL 1:2) exhibited high entrapment efficiency, spherical shape, particle size <200 nm, zeta potential of –31 mV and sustained drug release for up to 7 days (93%). These nanoparticles were further incorporated into an in situ forming thermosensitive hydrogel prepared with 18% Poloxamer 407 selected for its gelation near body temperature. The nanoparticle-loaded hydrogel demonstrated controlled drug release for 30 days with near zero-order kinetics and no burst effect. The formulation showed good biocompatibility and a pH similar to synovial fluid, minimizing irritation. This optimized formulation (PF9) effectively prolonged intraarticular retention and sustained drug delivery, reducing dosing frequency and offering a promising therapeutic strategy for long-term management.

**Keywords:** Osteoarthritis, Betamethasone dipropionate, Intra-articular drug delivery, Biodegradable nanoparticles, Thermosensitive hydrogel

**PC-39**

## NEXT-GENERATION HYDROGEL THERAPEUTICS: DUAL-DRUG SYSTEM FOR ORAL MUCOSITIS IN ONCOLOGY PATIENTS

Bhoomika S, Junaid Abdul Majeed, Jisha Mohan, Devi Sneha M
NITTE College of Pharmaceutical Sciences, Nitte deemed to be university, P. B. No.6429, Yelahanka, Bengaluru - 560064
bhoomi.pharmacist@gmail.com

Oral mucositis is a prevalent and painful inflammatory condition of the oral cavity, commonly affecting patients undergoing chemotherapy and radiotherapy. It severely impairs quality of life due to pain, ulceration, and difficulty in eating or speaking. Current management involves systemic steroids and mouth paints containing agents such as clotrimazole, benzalkonium chloride, and triamcinolone, but these often produce severe adverse effects, burning sensation, and poor patient compliance. To address these limitations, the present study aimed to formulate and evaluate a novel hydrogel containing dexamethasone and metronidazole for localized therapy of oral mucositis. The hydrogel was formulated with hydrophilic polymers and evaluated for pH, viscosity,

ISBN: 978-81-980623-8-3

Spreadability, drug content, and in-vitro release. Compatibility studies confirmed no drug–excipient interactions. The optimized formulation (F4) showed favourable physical properties, consistent drug distribution, and sustained release, achieving 97.25% dexamethasone release and 98.62% metronidazole release. In vitro antimicrobial studies showed metronidazole's effect against E. coli, and HET–CAM testing confirmed the formulation was non-irritant. In vivo evaluation in patients with oral mucositis associated with carcinoma buccal mucosa, oral cancer, and ulcerative lesions demonstrated 75–100% pain relief, significant reduction in discomfort, and better patient compliance compared to conventional therapies. The incorporation of dexamethasone provided strong anti-inflammatory action, while metronidazole effectively targeted pathogenic microorganisms, ensuring enhanced residence time and localized therapeutic effect. The hydrogel can be economically prepared at Rs. 45/- for a 10 ml tube, making it cost-effective. Overall, the developed dexamethasone-metronidazole hydrogel represents a promising, safe, and affordable localized therapy for oral mucositis.

## PREPARATION AND EVALUATION OF MORINGA CHEWABLE GUMMIES

Thejashree b c, Avril candida mathias
Department of Pharmaceutics, Nitte College of Pharmaceutical Sciences, Nitte (deemed to be university), Bengaluru-560064, Karnataka, India
thejashreebc02@gmail.com

Moringa chewable gummies are dietary supplements enriched with essential nutrients, designed to enhance overall health, particularly in individuals with nutrient deficiencies. The rising preference for chewable supplements is attributed to their convenience, pleasant taste, and improved compliance, especially among children and the elderly.In this study, moringa gummies were formulated using gelatin (gelling agent), stevia, moringa powder (active ingredient), citric acid, sodium benzoate, and flavouring agents. Two solutions were prepared: the first by mixing stevia and water (1:1), and the second by dissolving gelatin in water and heating to 60 °C. Both solutions were combined, followed by the incorporation of moringa and other excipients.Evaluation revealed that moringa gummies significantly improved nutrient absorption compared to conventional supplements. Their favourable taste and ease of consumption also enhanced adherence, overcoming challenges associated with swallowing tablets or capsules.Overall, moringa chewable gummies present a palatable and effective alternative to traditional pill-based supplementation. They offer a convenient means of improving nutrient intake, with promising implications for long-term health and compliance. Further research is needed to assess their sustained benefits and potential impact on broader health outcomes with regular use.

## INSILICO EVALUATION OF ANALGESIC ACTIVITY LINUM USITATISSIMUM

Sk. Nagul Meeravali
Department of Pharmacology, V. V. Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh, India- 521356
smeeravali27@gmail.com

Pain is regarded as an unpleasant feeling and emotional experience that is linked to possible tissue damage. Pain signals go through nerve fibers to the brain for interpretation, allowing the body to react and preventing more tissue damage. Pain can be brought on by a variety of mediators, including prostaglandins, cytokines, histamine, serotonin, substance P, and capsaicin. However, in order to defined the body against unknown invaders, substances like prostaglandins define and regulate cellular and tissue reactions including inflammation. There is proved animal studies about the analgesic activity of the respective plant extract of Linum Utiss but which phytoconstituent is responsible for the activity is not known. So we performed molecular docking studies to confirm the main ligand which is present in the plant is responsible for the analgesic activity. Molecular docking studies shows affinities of Daucosterol -10.8 to -8.0 Kcal/Mol which having mainly amino acid Serine A:530, Cycloartenol -10.2 to -7.2 Kcal/Mol mainly amino acids Glutamic acid A:236 and Leucine A:238, 24–Methylene cycloartanol -9.9 to -7.7 Kcal/Mol mainly amino acid Glutamine A:241 and Glutamic acid B:140 involved in the binding. while the standard drug shows the affinity of -8.1 Kcal/Mol.

## FORMULATION, EVALUATION AND OPTIMIZATION OF TRANSDERMAL DRUG DELIVERY SYSTEM CONTAINING NONSTEROIDAL ANTI INFLAMMATORY DRUGS

Hrushikesh Anantrao Joshi
Shivnagar Vidya Prasarak Mandal's College of Pharmacy, Malegaon Taluka Baramati
Dist. Pune Maharashtra, India- 413115
hrushikesh17@rediffmail.com

Transdermal drug delivery system (TDDS) offers various advantages over oral dosage forms form such predetermined release rate, avoiding first pass effect, patient. A hydrophilic or hydrophobic property of polymers governs drug release characteristics from TDDS. Stratum corneum offers resistant for penetration of certain drugs, hence permeation enhancer (PE) were used to improve permeation. In present research work matrix type TDDS were formulated and evaluated. The objective was to study the effects of polymer types and penetration enhancers on drug release kinetic and flux of containing diclofenac sodium and flurbiprofen. Eudragit RL 100 and Eudragit RS 100 were used as polymers and penetration enhancers such as DMSO, oleic acid and Tween 80 were evaluated. A three factor three level Box Behnken design (BBD) was employed in optimization of TDDS and penetration enhancers were selected as independent variables. Drug and polymer interactions were carried out by FTIR and DSC analysis and found no interactions. Invitro drug release studies were carried out using a modified Franz diffusion cell and results indicated selected penetration enhancers have effect on drug release kinetic and flux were increased. Skin irritation test and accelerated stability studies were carried to study skin irritancy and stability of TDDS. The results showed no irritation and optimized formulation was stable. It was concluded that that the optimized formulation demonstrated significant improvements in drug release and flux compared to other formulations. The optimized patch also met the criteria for physical properties such as smoothness, thickness uniformity, and folding endurance.

**Keywords:** Transdermal, Box-Behnken Design, Eudragit RL 100, Eudragit RS 100, penetration enhancers.

## DEVELOPMENT AND EVALUATION OF BILAYER TABLET OF ENZALUTAMIDE FOR PROSTATE CANCER THERAPY

Priyanshu Giripunje , Leena Rokade and Swati Gaikwad
Nagpur College of Pharmacy, Nagpur, Maharashtra, India - 441110.
priyanshugiripunje19@gmail.com

The present investigation was undertaken to design and evaluate a bilayer tablet of enzalutamide, an androgen receptor inhibitor used in the management of prostate cancer, with the objective of integrating both immediate and sustained drug delivery strategies in a single dosage form. The bilayer tablet was prepared by direct compression, which comprised two distinct layers. The immediate-release (IR) layer was formulated using sodium starch glycollate as a superdisintegrant to ensure rapid drug release, whereas the sustained-release (SR) layer was developed with Hydroxypropyl Methylcellulose (HPMC), a hydrophilic swellable polymer, to prolong drug release. Additional excipients, such as microcrystalline cellulose, lactose, and magnesium stearate, were incorporated to enhance compressibility, flow, and tablet uniformity. The formulated bilayer tablets were evaluated for physicochemical parameters, including hardness (1.2–3.9 kg/cm²), friability (0.12–0.58%), thickness (1.2–2.4 mm), and weight variation (1.56–2.36%). All values were within the pharmacopeial limits, indicating acceptable mechanical strength and consistency. In vitro dissolution studies revealed that the IR layer released the drug rapidly within 30 min, providing an immediate therapeutic effect, whereas the SR layer sustained drug release over 8 h, thereby maintaining prolonged plasma levels. This study demonstrates that a bilayer tablet of enzalutamide can be successfully formulated to

ISBN: 978-81-980623-8-3

achieve dual-release kinetics, offering the dual advantage of rapid onset of action and extended therapeutic coverage. This approach holds promise for improving therapeutic efficacy, minimizing dosing frequency, and enhancing patient compliance in the management of prostate cancer.

**Keywords:** Enzalutamide, Bilayer tablet, Immediate release, Sustained release, Prostate cancer

**PC-44**

**PREPARATION, CHARACTERIZATION & OPTIMIZATION OF PIMOZIDE MUCOADHESIVE NANOEMULSION USING BOX-BEHNKEN DESIGN: IN VITRO AND IN VIVO STUDIES FOR NOSE-TO-BRAIN DELIVERY**

Biswajit Basu, Suraj Mallick, Shreyasi Majumder, Rajdip Goswami, Bhupendra Prajapati

bbasu.pharma@gmail.com

Tourette Syndrome (TS) is a complex neurodevelopmental disorder characterized by persistent motor and vocal tics, frequently accompanied by comorbidities such as attention deficit hyperactivity disorder (ADHD) and obsessive-compulsive disorder (OCD). Pimozide is an FDA-approved dopamine receptor antagonist that treats TS, but its poor water solubility and extensive first-pass metabolism, together with systemic side effects, limit its therapeutic applications. The objective of this study was to develop a mucoadhesive nanoemulsion (PIM-MNE) of pimozide for intranasal nose-to-brain delivery to increase nasomucosal adhesion while enhancing brain bioavailability and reducing systemic toxicity. Box–Behnken statistical design helped determine essential formulation variables that affected nanoemulsion (PIM-NE) droplet size, along with polydispersity index and surface charge. PIM-MNE was obtained by incorporating GRAS mucoadhesive polymer, Carbopol 971, in the optimized NE. The optimized PIM-MNE, which exhibited favorable physicochemical properties with a globule size of 57.82 nm ± 0.25 nm, PDI 0.35 ± 0.03 nm, zeta potential −23.40 mV ± 0.32 nm, high entrapment efficiency 92.80%, and drug loading 44.6%. In vitro drug release studies demonstrated sustained release of 91.5%. Stability studies confirmed that the formulations remained stable for three months under both ambient and refrigerated conditions. The ex vivo permeation tests showed that the nanoemulsion had better mucosal absorption than the pimozide solution. In vivo pharmacokinetic studies confirmed improved brain targeting efficiency compared to conventional formulations. The histopathological examination demonstrated mucosal safety through the absence of tissue damage. Collectively, these results indicate that intranasal PIM-MNE serves as an effective non-invasive delivery system that directs pimozide to the brain while lowering systemic adverse effects for treating Tourette's Syndrome.

**COLON-TARGETED MICROPARTICLE FOR TARGETED DRUG DELIVERY IN INFLAMMATORY BOWEL DISEASE**

Raju Samanta*, Rajdip Goswami, Sanjay Dey
Department of Pharmaceutical Technology, School of Health and Medical Sciences
Adamas University, Barasat, Kolkata, 700126
mailtorajusamanta@gmail.com

Inflammatory Bowel Disease (IBD), which includes ulcerative colitis and Crohn's disease, which is targeted drug administration to the colon to enhance therapeutic effectiveness and reduce systemic adverse effects of the drug. Conventional oral formulations frequently experience early drug release and inadequate site-specific bioavailability. Colon-targeted microparticles is a great option, porous polymeric fabric, which facilitates significant drug loading, ensures targeted drug release at the targeted site that is colon. Formulated microparticles can be customised with pH-sensitive polymers and enzyme-responsive coatings to provide targeted drug release in the colonic area. This method not only promotes therapeutic results but also increases patient compliance by drug efficiency and side effects. The discussion will emphasise the synthesis methodologies, characterisation parameters, release mechanisms, and techniques of colon-targeted microparticle, while also addressing their potential for delivering anti-inflammatory drugs in the management of inflammatory bowel disease (IBD). microparticles offer a feasible and unique formulation for enhancing colon-targeted drug delivery systems due to their capacity for site-specific, targeted drug release and stability in gastrointestinal environments.

**GLASS IONOMER CEMENTS AS SUSTAINED DRUG DELIVERY SYSTEMS IN DENTISTRY**

Suankit Harane, Vinita Kale, Milind Umekar
Department of Regulatory Affairs, Smt. Kishoritai Bhoyar College of Pharmacy Kamptee – 441002
Suankit.harane92@gmail.com

Glass Ionomer Cements (GICs) are commonly used in restorative dentistry because of their biocompatibility, ability to chemically bond with tooth structures, and inherent fluoride release. Despite these advantages, conventional GICs release fluoride in an initial burst followed by a rapid decline, which significantly limits their long-term therapeutic effectiveness. This limitation weakens their sustained antimicrobial and remineralization potential both essential for preventing secondary caries and ensuring tooth longevity. As a result, conventional GICs are unable to provide continuous therapeutic benefits. To address this limitation, recent research has focused on incorporating bioactive nanoparticles into GICs, with the aim of improving antimicrobial activity, mechanical performance, and remineralization capacity. However, systematic evaluation of these modifications is still required to establish their effectiveness as sustained drug delivery systems in restorative dentistry. This study aims to evaluate the role of modified GICs as sustained drug delivery systems in dentistry, with a focus on their antimicrobial, remineralization, and mechanical properties using nanotechnology with green approach. Modifications include incorporation of green synthesized nanoparticles to enhance performance. Antimicrobial activity was assessed using Zone of Inhibition (ZOI) and Minimum Inhibitory Concentration (MIC), remineralization potential was measured by Vickers hardness test, and mechanical strength was evaluated using a universal testing machine. Silver nanoparticle (AgNP)-modified GICs demonstrated significant antibacterial activity against Streptococcus mutans. Titanium dioxide ($TiO_2$) nanoparticles improved mechanical strength, while calcium phosphate nanoparticles exhibited notable remineralization potential while maintaining strength within clinically acceptable limits. Nanoparticle-modified GICs exhibit enhanced antimicrobial activity, improved or sustained mechanical strength, and added remineralization benefits, highlighting their potential as dual-function restorative materials and sustained drug delivery systems in modern dentistry.

sophiakodamanchili@gmail.com

Acyclovir is a popular anti-Herpes drug among the antiviral category for the treatment of diseases including Herpes Simplex, Keratitis etc. Acyclovir is the drug of choice for most of these cases but the problem of using this drug is that it has poor oral bioavailability. The conventional routes and therapies available for the treatment of Herpes, Keratitis, includes orally administered tablets but are associated with it is very low bioavailability ranging from 15-30%. Repeated administration of high doses result in infrequent nausea, diarrhoea, rash, and headache. This

ISBN: 978-81-980623-8-3

Problem can be resolved by enhancing the solubility and hence dissolution of poorly water soluble drug acyclovir. The aim of the present study was to formulate and evaluate Acyclovir solid dispersions by gel entrapment method using HPMC E5 and HPMC E15 in the ratios of 1:1, 1:2 and 1:3. The prepared solid dispersions were evaluated for FTIR studies, DSC, drug content, drug release studies and aqueous solubility studies. Acyclovir solid dispersions released the drug up to 96% for one hour in 0.1 N HCl. The drug content was found to be maximum as 98%. The results showing that the solubility of Acyclovir was increased by formulating into solid dispersions.

**Keywords:** Acyclovir, keratitis, solubility, bioavailability, solid dispersion.

**DESIGN AND CHARACTERIZATION OF NANOFIBERS FOR DUAL DELIVERY OF PHYTOCONSTITUENT AND ANTI-EGFR AGENTS IN ORAL CANCER THERAPY**

Tejal Mehta, Anam Sami a, Jigna Shah a, Henna Dave
Institute of Pharmacy, Nirma University, S. G. Highway, Ahmedabad - 382 481, Gujarat, India
Institute of Science & Institute of Pharmacy, Nirma University, S. G. Highway, Ahmedabad - 382481, Gujarat, INDIA
tejal.shah@nirmauni.ac.in

Oral cancer is a major worldwide health issue, causing substantial morbidity and death, particularly in underdeveloped nations. Therefore, novel drug delivery systems capable of improving therapeutic efficacy while minimizing systemic toxicity are urgently needed. Nanofibers have emerged as a versatile platform for localized and controlled drug delivery due to their high surface area-to-volume ratio, tunable porosity, and ability to mimic the extracellular matrix. In this study, electrospun nanofibers were developed as a co-delivery system incorporating a phytoconstituent alongside an anti-EGFR agent. The formulations were systematically characterized using FTIR for functional group interactions, DSC for thermal behavior, NMR for structural confirmation, and XRD to assess crystallinity changes and confirmation upon encapsulation of the drug and SEM which confirmed the nanofiber structure and size (200-300 nm). In vitro drug release studies demonstrated a sustained and controlled release upto 85% drug release in 8 hours. Cytotoxicity was assessed using MTT assay obtaining IC50 at 45.23 µm , while scratch wound healing assay was employed to evaluate the inhibition of cancer cell migration. Cell culture studies revealed a dose-dependent reduction in cell viability, with nanofiber formulations showing significantly higher cytotoxicity compared to free drug counterparts ($p < 0.05$). Furthermore, scratch assay results demonstrated marked inhibition of cancer cell migration, indicating enhanced anti-migratory potential of the dual-drug nanofibers. Collectively, the findings suggest that the phytoconstituent–anti-EGFR nanofiber system provides synergistic anticancer effects with prolonged drug availability, offering a promising therapeutic strategy for oral cancer.

**FORMULATION AND EVALUATION OF MANGIFERIN ANTI-DIABETIC NASAL SPRAY BY QBD METHOD**

Qazi Abrar Mustafa Siddiqui, Furquan Nazimuddin Khan, Mariya Rubat
Maulana Azad Educational Trust's Y.B Chavan College of Pharmacy, Aurangabad, Maharashtra, India-431001
qaziabrarmustafa@gmail.com

The formulation and evaluation of a Mangiferin nasal spray for the potential management of type II diabetes. Mangiferin, a bioactive compound isolated from Mangifera indica leaves, It has several therapeutic effects, including anti-diabetic effects, but its efficacy is limited by poor bioavailability due to first pass metabolism and low solubility. The nasal route was selected to overcome the first-pass metabolism and allows for rapid systemic drug absorption. Mangiferin was extracted from mango leaves, and it's purity was confirmed by the characterization tests like melting point determination and UV and TLC analysis. Preformulation studies were conducted to determine the drug's solubility in various solubilizers, with phenylethyl alcohol (PEA) showing the highest solubility A Stable nasal spray formulation was developed using Mangiferin, Poloxamer, PEA and Oleic acid. A Quality by Design approach utilizing a Box-Behnken design was implemented to optimize the formulation was evaluated for physicochemical characteristics, including pH, viscosity, spray pattern, plume geometry, and the drug content. In this three level four factors is used in which 12 experiments are runs. It helps in determining the source of variability in nasal spray and how to control that variability. The optimized spray demonstrated a suitable pH(6-6.5) and viscosity (0.0025Ns/m2). Stability Analysis confirmed the significance of the experimental model, including a successfully developed, stable Mangiferin nasal spray.

**Keywords**: Mangiferin, Nasal Spray, Anti-Diabetes, Quality by design, Preformulation studies.

**DEVELOPMENT, OPTIMIZATION AND CHARACTERIZATION OF NOVEL GAULTHERIA OIL-PIROXICAM MICROEMULSION BASED HYDROGELS FOR TRANSDERMAL DELIVERY IN THE TREATMENT OF ARTHRITIS**

Vani Setty, Venkatesan Natarajan, Chandrasekar Sandanapalli Basavarajaiah, Sreedhar Chandanam
School of Pharmacy, Department of Pharmaceutics, Sri Balaji Vidyapeeth, Deemed-to-be University, Pillayarkuppam-607402, Pondicherry, India
vanisramu@gmail.com

The aim of the present research was to formulate a novel microemulsion based hydrogel (MEH) of gaultheria oil for topical delivery of Piroxicam and evaluated for in-vivo anti-inflammatory & in-vivo anti-arthritic activity. The objective behind the research was to examine the suitability of gaultheria oil in formulating microemulsions (MEs) of Piroxicam for enhanced anti-inflammatory and anti-arthritic effects. The MEs were formulated with surfactant and co-surfactants (S-mix) determined from pseudo ternary phase diagrams and phase titration method. Optimization of MEs was performed using D-optimal design expert software and evaluated for qualitative and quantitative tests. The optimized microemulsion (ME) was fabricated into hydrogels using HPMC K100M in different proportions and evaluated for pH, viscosity, spreadability, drug content, diffusion study, in-vitro drug release studies, in-vivo anti-inflammatory (Croton oil ear edema model) and in-vivo anti-arthritic (Complete Freund's Adjuvant model) activity. It was found that the evaluated parameters such as, pH (7.42), viscosity (6847cps), spreadability (4.54 g.cm/sec), drug content (95.81%), in-vitro diffusion (93.25%), in-vitro cumulative drug release for 12 hours (89.95%) was suitable for dermal application with sustained release characteristics, also exhibited enhanced anti-inflammatory and anti-arthritic activity which is statistically very significant when compared with that of the marketed formulation. The stability studies demonstrated that the formulated MEH was stable as per International Conference on Harmonization (ICH) guidelines. Thus, it can be concluded that, the study can be beneficial for the formulation of MEH using gaultheria oil as a novel encapsulating vehicle for transdermal delivery of Piroxicam.

**Keywords:** Gaultheria oil, piroxicam, microemulsion based hydrogels, anti-inflammatory, anti-arthritic.

**FORMULATION AND EVALUATION OF UFASOMAL GEL LOADED WITH NORFLOXACIN TO TREAT BACTERIAL INFECTION USING FACTORIAL DESIGN**

LIKHITH G K*, SNEHALATHA, MARUTHI N
Department of Pharmaceutics, SJM College of Pharmacy, Chitradurga, Karnataka, India-577502
likhithgkliki@gmail.com

To formulate and evaluate a ufasomal gel loaded with Norfloxacin for controlled transdermal delivery using factorial design. A novel ufasomal gel formulation containing Norfloxacin was developed and assessed for the topical treatment of bacterial infections, including Staphylococcus aureus, utilizing factorial design. The gel was prepared using lipid film hydration technique, incorporating fatty acid vesicles as carriers to enhance drug permeation across the skin. Factorial design was applied to systematically optimize critical formulation parameters such as lipid concentration, surfactant ratio and Norfloxacin content. The optimized ufasomal gel exhibited desirable physicochemical properties, including homogeneity, particle size, viscosity, spreadability, appropriate pH and high drug entrapment efficiency (above 80%), with average vesicle size supporting effective transdermal delivery. In-vitro drug release studies demonstrated sustained Norfloxacin release from the ufasomal gel-with

ISBN: 978-81-980623-8-3

approximately 63-72% release over 8 hours-indicating prolonged therapeutic levels of the antibiotic. Additionally, in-vitro antibacterial assays confirmed robust inhibition of target bacteria, with reduced minimum inhibitory concentration (MIC) for the ufasomal gel compared to pure drug solution, signifying potent antimicrobial activity. Stability investigations revealed that the gel remained physically and chemically stable under standard storage conditions for an extended period. Overall, factorially optimized Norfloxacin-loaded ufasomal gel achieves controlled and extended topical drug release, improved skin permeation and effective antibacterial therapy for transdermal applications.

**Keywords:** Norfloxacin, Span 60, Cholesterol, Oleic acid, Tween 80, Trimethanolamine, Carbopol, Sodium oleate.

## FORMULATION AND EVALUATION OF IN-SITU GEL LOADED WITH MICROSPONGES OF SUMATRIPTAN SUCCINATE FOR MIGRAINE THERAPY

Rashmi Surve and Meraj Shaikh
Department of Pharmaceutics, Rani Chennamma College of Pharmacy, Belagavi-10, Karnataka, India.
rashmisurve08@gmail.com

The nasal route has proven to be a useful means for targeting drugs to the central nervous system. Utilizing the nasal mucosa as a drug delivery target confers several advantages, including a relatively expansive surface area for absorption and the avoidance of first pass metabolism. Traditional nasal sprays and drops often suffer from low bioavailability and limited therapeutic response due to rapid nasal elimination. This limitation can be addressed through in-situ gelling systems, which transform liquid drops to gel within the nasal cavity. In this study, we attempted to enhance the therapeutic effectiveness of Sumatriptan succinate while mitigating systemic side effects by formulating it as microsponges within an in-situ gel for nasal drug delivery. The microsponges were formulated using the quasi-emulsion solvent diffusion technique and were subsequently integrated into in-situ gel. We attempted varying proportions of Ethyl cellulose polymer in combination with the drug to fabricate the microsponges. Various parameters were meticulously assessed to identify the optimal formulation. Our findings revealed that Formula F6, with a drug-to-polymer ratio of 1:6, exhibited substantial entrapment efficiency of approximately 60.66 ± 4 and possessed a mean particle size of around 111±0.35 micrometers and showed a controlled drug release of 64.1992% in 8 hours. Furthermore, the physicochemical attributes of the in-situ gels, including pH, gelling capacity, gelation time, and rheological properties, were evaluated. Notably, formulation ISG 3 demonstrated controlled drug release when compared to other formulations. These results underscore the potential of Sumatriptan succinate microsponges in in-situ gel form for nasal drug delivery.

**Keywords:** Sumatriptan succinate, microsponges, in-situ gel, migraine

## SYNTHESIS AND CHARACTERIZATION OF CHITOSAN ENCAPSULATED SILVER NANOPARTICLES FROM THE FRUIT EXTRACT OF GARCINIA GUMMI-GUTTA FOR ITS IN-VITRO EVALUATION OF ANTHELMINTIC ACTIVITY

Ms. Asfiya Siddiqha, Tripathy Amrutanand S and Bhoomika
Sri Adichunchanagiri College of Pharmacy, Adichunchanagiri University, B.G. Nagara, Mandya, Karnataka, India – 571418.
siddiqhaasfiya@gmail.com

Intestinal helminthiases are infections in which adult helminths parasitize the intestine. The rise in drug-resistant helminth infections presents a significant challenge in global health, necessitating the exploration of innovative therapeutic approaches like silver nanoparticles, possessing potent anthelmintic properties and can enhance drug efficacy when combined with biopolymers. The fruit rind of Garcinia gummi-gutta has traditionally been used to treat gastrointestinal problems. In this study, AgNPs were synthesized using a chemical reduction method with hydroalcoholic extract of dried GGG fruit. The resulting AgNPs were then encapsulated with chitosan. Characterization of GFE+Cs-AgNPs was performed using Particle size and Zeta potential, UV-Vis spectroscopy, SEM with EDX, FTIR and XRD, to confirm synthesis, assess size and morphology. The anthelmintic activity of the GFE+Cs-AgNPs was compared with standard albendazole and evaluated against the earthworms Pheretima posthuma by analysing paralysis and death time. UV-Vis spectroscopy indicated formation of AgNPs, with a peak at 300-400 nm. SEM analysis showed agglomerates of dispersed AgNPs ranging from 95-114 nm. FTIR results confirmed the involvement of functional groups in stabilizing the nanoparticles. XRD patterns revealed the morphology of GFE+Cs-AgNPs as face-centered cubic. In-vitro anthelmintic activity showed that, the paralysis and death of worms was earlier at higher concentrations of GFE+Cs-AgNPs (2µg/ml) at 10±2 mins and 17±2 mins, Std (20mg/ml) at 6±2 mins and 9±2 mins respectively. The In-vitro anthelmintic activity revealed a significant dose-dependent reduction in motility and viability of the tested earthworms, suggesting strong potential for these nanoparticles as anthelmintic agents.

**Keywords:** Anthelmintic activity, Chitosan, Garcinia gummi-gutta, Helminthiasis, Silver nanoparticles.

## DESIGN, DEVELOPMENT AND STANDARDISATION OF CHEWABLE TABLET FOR OSTEOARTHRITIS

Vaishali S Ghorpade*, A. R. Pawar, R. B. Pandhare, V. K. Deshmukh
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist- Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
vaishnavighorpade2005@gmail.com

Osteoarthritis is musculoskeletal disorder causes joint pain and stiffness in affected area. Boswellia serrata has proven potential anti-inflammatory activity to treat osteoarthritis. NSAID's which are commonly used for treatment of osteoarthritis are ulcerogenic when taken for long duration. Boswellia serrata has found to be safe for long term use. Patients who are not able to swallow tablet which having bitter taste and odour for that chewable tablet become an alternative option, so we developed chewable tablet of Boswellia serrata extract. Chewable tablet containing Boswellia serrata extract (40%) formulated with suitable binder, disintegrants, fillers, sweetener, flavour and colour. Potato starch paste with water was used to prepared granules with wet granulation method. Prepared granules dried in oven and then lubrication performed with suitable lubricants. Prepared chewable tablets subjected to voluntaries to check the taste, comfort for chewing. Chewable tablets have been found to be acceptable by voluntaries. Pre-compression and post-compression test parameters for chewable tablets were performed. Optimised batch were evaluated for pre-compression and post-compression parameters and all results found under limits. Selected optimised three batches give reproducible result. Through in-vitro study on formulation of Boswellia chewable tablet, we have conclude that dosage form is accepted by voluntaries for its taste, flavour and ease of use.

**Keywords:** Osteoarthritis; Boswellia serrata; Chewable Tablet, Stability studies

## DEVELOPMENT OF PANCHAGAVYA GHRITA NANOVESICULAR SYSTEMS: A NATURAL PHOSPHOLIPID-BASED APPROACH FOR TRANSDERMAL DRUG DELIVERY

Ms. Ruchi Khobragade, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India-441002
ruchirakeshk@gmail.com

Panchagavya Ghrita (PG), a traditional Ayurvedic formulation, possesses therapeutic benefits such as wound healing, immunomodulation, and neuroprotection. However, its clinical use is limited by poor stability, unpalatability, and low patient compliance. This study aimed to formulate PG into a nanovesicular system utilizing its natural phospholipids and develop a transdermal liposomal gel. Nanovesicles were prepared using the thin film hydration method and optimized with a $3^2$ factorial design by varying cholesterol and Span 80 concentrations. The optimized liposomal formulation (batch F9) had a particle size of 388.9 nm with a polydispersity index of 0.261 and a zeta potential of –55.3 mV, indicating good colloidal stability. Entrapment efficiency was 88.9% and drug content 70.65%. FTIR analysis showed no drug-excipient interaction. In vitro drug release demonstrated sustained release over 12 hours, with 40.11% release at 5 hours and 88.47% at 12 hours, in contrast to rapid release from traditional PG. The liposomal gel exhibited suitable pH (5.8), viscosity (17,750 cps), and spreadability (15

ISBN: 978-81-980623-8-3

gm.cm/sec), and maintained stability under accelerated storage conditions. The developed nanovesicular system provides a formulation of PG with improved stability, controlled drug release, and transdermal delivery characteristics while potentially increasing patient compliance. This system also offers a potential platform for delivering other poorly soluble natural compounds.

## EXPLORATION OF HYDROGEL BEADS OF NIZATIDINE HYDROCHLORIDE IN GASTROINTESTINAL ULCERS

Umesh Kumar Singh, Preethi Sudheer, Sachin Gowda BN
Krupanidhi College of Pharmacy, Bangalore, Karnataka, India
Nitte College of Pharmaceutical Sciences, Bangalore, Karnataka,India
gowdabnsachin@gmail.com

Objectives: Nizatidine is a histamine H2 receptor antagonist used to treat gastric and duodenal ulcers. Its short half-life requires frequent administration, leading to patient incompliance. The primary purpose was to develop hydrogel beads for prolonged drug action. Materials and Methods: Hydrogel beads were prepared by ionotropic gelation using gellan gum, aluminum trichloride as cross-linking agent, and Tween 80 as stabilizer. FTIR assessed drug-excipient compatibility. Full factorial design trials were evaluated for drug entrapment efficiency and in vitro drug release. The optimum formula was studied using SEM, DSC, mucoadhesion time, swelling index, and drug release kinetics. Results: Drug entrapment efficiency ranged from 86.33±0.013 to 95.05±0.05%, and in vitro drug release was 82.57±0.065 to 93.37±0.049% for 10h. The swelling index of optimized formulation was 71.9±0.03% at 6h. Drug release followed zero-order kinetics and Korsmeyer-Peppas model. SEM results showed irregular beads with uneven, dense surfaces after drying. FTIR spectra indicated no considerable chemical interactions between drug and excipients. Stability studies showed no substantial changes in parameters. Conclusion: The study concluded that nizatidine-gellan gum hydrogel beads are a promising, biocompatible approach to achieve therapeutic action by controlling drug release rate in gastrointestinal ulcer treatment.

**Keywords:** Nizatidine, hydrogel beads, ionotropic gelation, gellan gum, aluminium trichloride

**PC-57**

## FORMULATION AND DEVELOPMENT OF ELASTIC VESICLE AS DRUG CARRIER FOR OPHTHALMIC DRUG DELIVERY SYSTEM

Pravinkumar Suruse, Vinod Thakre and Shital Tathe
Department of Pharmaceutics, Nagpur College of Pharmacy, Nagpur, Maharashtra, India-441110.
pravinsuruse@gmail.com

Ciprofloxacin hydrochloride, a second-generation fluoroquinolone derivative, is widely used for the treatment of ocular infections. However, its conventional solution dosage form requires frequent administration due to rapid precorneal elimination and limited ocular residence time. Vesicular drug delivery systems have been reported to prolong and control drug action at the corneal surface, but they still face challenges such as tear-mediated drainage. In the present study, an attempt was made to formulate niosomes encapsulating Ciprofloxacin HCL using a $3^2$ full factorial design. The prepared niosomes were evaluated for vesicle size, percent drug entrapment efficiency, in-vitro drug release kinetics, and stability. To further enhance ocular retention, an in- situ gel system was developed by dispersing the niosomes in a polymeric matrix containing Carbopol 940 and Hydroxypropyl methylcellulose (HPMC K4M). The in-vitro release profile of the niosomal in-situ gel demonstrated sustained drug release, with the minimum inhibitory concentration (MIC) of 4 µg/ml achieved within 1-2 hours. The findings suggest that niosomal in- situ gel formulations hold significant potential as novel carriers for effective and sustained ophthalmic delivery of Ciprofloxacin HCL.

**Keywords:** Niosomes, In-situ gel, Ophthalmic drug delivery, Ciprofloxacin HCL, Factorial design.

## FABRICATION, CHARACTERISATION AND OPTIMIZATION OF GLIMEPIRIDE NANOCRYSTALS USING PROBE SONICATION METHOD FOR AUGMENTING SOLUBILITY

Gouri Dixit and Samiksha Tammewar
Department of Pharmaceutics, Priyadarshini J. L. College of Pharmacy, Electronic Zone, MIDC, Hingna Road, Nagpur, Maharashtra, India – 440016.
gouridixit77@gmail.com

Poor aqueous solubility is a major obstacle to the oral bioavailability of Biopharmaceutics Classification System (BCS) Class II drugs, where dissolution is the rate-limiting step. This study aimed to develop and optimize glimepiride nanocrystals to enhance their solubility and oral bioavailability. Glimepiride, an antidiabetic drug with high permeability but low solubility, was selected as the model compound. Nanocrystals were prepared using an Anti-Solvent precipitation and probe sonication technique with Soluplus and PVP K30 as stabilizers. Preformulation studies confirmed drug identity and purity via FTIR and DSC analyses. Solubility and dissolution studies demonstrated markedly improved performance of nanocrystal batches compared with the pure drug across various media. Among eleven formulations, Batch F3 (Soluplus 10 mg) showed the highest solubility (4.52 mg/mL in phosphate buffer pH 6.8), approximately an eight-fold increase over the pure drug. Optimization using central composite design identified polymer concentration and stirring speed as critical factors influencing solubility and particle size. The optimized nanocrystal formulation achieved a solubility of 4.52 mg/mL with a mean particle size of 176 nm, PDI of 0.183, and zeta potential of –26.5 mV, indicating good homogeneity and electrostatic stability. Drug content of GLM Nanocrystals was approx.92%, suggesting minimal processing losses. Ex vivo permeation studies using excised intestinal tissue confirmed enhanced solubility of GLM nanocrystals compared with the pure drug, while preliminary in vivo pharmacokinetic evaluation in rats demonstrated significantly improved oral bioavailability. These findings underscore nanocrystal technology using probe sonication method as a robust platform to overcome dissolution limitations of BCS Class II drugs and support its potential for scalable, patient-compliant oral delivery system.

**Keywords:** Glimepiride, BCS Class II, Nanocrystals, Anti - Solvent Precipitation technique, Probe sonicator.

## FORMULATION, PREPARATION AND EVALUATION OF SITAGLIPTIN CONTROL-RELEASE TABLETS BY USING TERMINALIA CATAPPA GUM

Nadakuduru Sailaja
Department of Pharmaceutics, VJ's College of Pharmacy, Diwancheruvu, Rajahmundry, Andhra Pradesh, India – 533296.
shailunadakuduru404@gmail.com

The present study was aimed at the formulation and evaluation of controlled release tablets of Sitagliptin, an antidiabetic drug, using Terminalia catappa gum as a natural polymeric release retarding agent. Sitagliptin, a selective DPP-4 inhibitor, has a short half-life and requires frequent dosing, which may lead to poor patient compliance. The use of natural gums as release modifiers is gaining significant importance due to their biocompatibility, safety, biodegradability, and cost-effectiveness. In this study, Terminalia catappa gum was extracted, purified, and incorporated into matrix tablets by the direct compression method at varying concentrations. The prepared formulations were subjected to evaluation for pre-compression parameters (flow properties) and post-compression parameters such as hardness, friability, weight variation, thickness, and drug content uniformity. In vitro drug release studies were performed using a USP dissolution apparatus in phosphate buffer (pH 6.8) to simulate intestinal fluid. The results demonstrated that increasing concentrations of Terminalia catappa gum progressively retarded the release of Sitagliptin, achieving controlled release up to 12 hours. The optimized formulation showed drug release kinetics following Higuchi's model with a non-Fickian diffusion mechanism. Stability studies confirmed that the selected formulation was stable under accelerated storage conditions. The study concludes that Terminalia catappa gum can be effectively used as a natural, safe, and economical polymer for the development of controlled-release Sitagliptin tablets, thereby enhancing patient compliance in diabetes management.

**FORMULATION AND CHARACTERIZATION OF NOVEL CO-CRYSTALLIZED VALSARTAN FLOATING TABLETS FOR PULSATILE AND CHRONOTHERAPEUTIC MANAGEMENT OF CARDIOVASCULAR DISEASES**

Prithwiraj Karmakar, Sujan Pal, Rajdip Goswami, Sanjay Dey*,
Department of Pharmaceutical Technology, School of Health and Medical Sciences,
Adamas University, Kolkata, 700126,
prithwiraj03.08.01@gmail.com

Pulsatile Drug Delivery Systems (PDDS) are new formulations designed to quickly release medications after a set delay. These systems ensure that medication is given in the right dose, at the right time, and at the right place. This improves both treatment outcomes and patient adherence. PDDS work well with the body's natural circadian rhythm, which affects sleep and various bodily processes. By syncing drug release with these rhythms, PDDS enhance time-related effects and reduce side effects.PDDS can be made as single-unit systems, such as capsular, osmotic, erodible, or rupturable coatings, or as multiple-unit systems, which include membrane-based, rupturable, or osmotic-rupturable types. In this study, Valsartan was selected for formulation. It is a BCS Class II drug, meaning it has high permeability but low solubility. A co-crystallization method was used to tackle its low solubility. We applied a Quality by Design (QbD) approach using Design of Experiments (DoE) software. We employed factorial design to improve a fast-dissolving tablet. Sodium Starch Glycolate (SSG) and Croscarmellose Sodium (CCS) acted as superdisintegrants, while mucilage from Hibiscus leaves was used as a natural polymeric coating agent to control release.This research highlights PDDS as an effective strategy for managing hypertension. It increases solubility, improves bioavailability, and enables controlled pulsatile release of Valsartan. This approach not only addresses patient adherence but also lowers side effects, making PDDS a vital part of innovative drug delivery research.

**Keywords:** Pulsatile Drug Delivery System (PDDS), Circadian Rhythm, Valsartan, Co-crystallization, Quality by Design (QbD), Hibiscus Leaf Mucilage.

**PREPARATION AND CHARACTERIZATION OF LIPOSOME LOADED DISSOLVABLE MICRONEEDLES**

Sanju Singh, Devendra Kumar Bhopte
Sri Sathya Sai Institute of Pharmaceutical Sciences, RKDF University, Gandhi Nagar Gondermou, Bhopal, Madhya Pradesh, India, 462033
Sanju.singh.sikarwar@gmail.com

The current study Include the preparation of liposome loaded dissolvable microneedles. The basic need of research is Liposome and microneedles are novel drug delivery system will affect the release profile of the drugs by minimizing the side effects. The major problem with the orals for is nausea, vomiting, sores in mouth, first pass metabolism, liver working problems that can be cured by the microneedles. The parenteral route having the disadvantage of pain that can relieved by microneedles.Microneedles are new transdermal drug delivery systems, which enhance permeability and improve the transdermal delivery efficiency of drugs more effectively compared with others technology.Based on this, the combination of liposomes and dissolvable microneedles is an effective strategy that may improve the permeability of drugs and regulate drug release at the same time. The major problem with the topical route is the barrier of the stratum cornium, which of drugs cannot cross by some drugs, this problem can also be altered by the use of the microneedles. Anakinra drug is an IL-1 antagonist for the management of Rheumatiod arthritis. There is no wastage of drug is possible, which will happens in the other dosage form. The work reduces the toxicity occurs due to the repeated administration of drug causes by the accumulation in the body.Self-medication is possible in the microneedles and the it was a painless process for administration of drug insertion into intra dermal route

**Keywords:** Liposomes, Dissolvable Microneedles, Anakinra, IL-1 antagonist.

**PC-62**

**DEVELOPMENT AND ANTIMICROBIAL ASSESSMENT OF AN HERBAL GEL INCORPORATING ETHANOLIC EXTRACT OF MUKIA MADERASPATANA (L)**

Naveenkumar P Kumarasamyraja D Jeevitha B Annakamatchi G
Department of Pharmaceutics, PGP College of Pharmaceutical Science and Research Institute, Namakkal, Tamil Nadu, India-637207
Naveen90854@gmail.com

The present study aimed to develop and evaluate an herbal gel formulation containing the ethanolic extract of Mukia maderaspatana (L.), focusing on its antimicrobial efficacy and wound healing potential. Mukia maderaspatana (L.), a traditionally used medicinal plant, was collected from Namakkal, Tamil Nadu, authenticated, and subjected to systematic processing, including Physicochemical parameters such as total ash, acid-insoluble ash, water-soluble ash, and extractive values were assessed, confirming the purity and quality of the plant material. Phytochemical screening revealed the presence of biologically active constituents such as alkaloids, flavonoids, cardiac glycosides, saponins, tannins, and steroids, with the absence of carbohydrates, proteins, mucilage, and fixed oils. Herbal gels were formulated using Carbopol 934, ethanol extract at varying concentrations (0.1%, 0.15%, 0.2%, and 0.25%), and standard excipients. The herbal gel formulation was evaluated for physical appearance, homogeneity, pH, viscosity, and spreadability, all of which showed favorable characteristics. In-vitro antimicrobial activity was tested against Staphylococcus aureus, Bacillus subtilis, Escherichia coli, and Pseudomonas aeruginosa using the disc diffusion method. The ethanolic extract demonstrated significant antimicrobial activity, with the highest inhibition zones observed at 300 µg/mL. The formulated herbal gel also exhibited antimicrobial activity but to a slightly lesser extent than the pure extract. Statistical analysis confirmed the significance of the results ($p<0.05$). The study concludes that Mukia maderaspatana (L.) ethanolic extract possesses notable antimicrobial properties and can be successfully formulated into a stable herbal gel with potential application in wound healing and topical antimicrobial treatment.

**Keywords:** Herbal gel, Mukia Maderaspatana, Carbopol 934, antimicrobial activity

**FORMULATION AND EVALUATION OF POLYMERIC NANO MICELLES CONTAINING AN ANTI CANCER AGENT**

Harsha Shivappa, Lokesh R, Vinayaka T M
Aditya Bangalore Institute of Pharmacy Education and Research
Shivappaharsha123@gmail.com

This study was undertaken to develop nanomicelles encapsulating Sorafenib tosylate using a Quality by Design (QbD) approach, aiming to enhance oral drug delivery and performance. Nanomicelles were fabricated via a dry-down (evaporation) method, and a definitive screening design was employed to evaluate the effect of key formulation and process variables, including drug amount, drug-to-polymer ratio, polymer-to-polymer ratio, types and ratios of polymer and stabilizer, as well as sonication settings. The primary response variables were particle size and entrapment efficiency. Entrapment efficiencies ranged from 80.2±3.81% to 96.83±4.12%, while particle sizes varied between 101.2 nm and 190.5 nm, accompanied by polydispersity index values of 0.203 to 0.345. In vitro drug release profiles were best described by the Korsmeyer- Peppas kinetic model, with "n" values between 0.5847±0.054 and 0.7311±0.077, indicating non-Fickian (anomalous) diffusion as the main release mechanism. The amount of drug demonstrated a significant positive impact on particle size and a negative impact on entrapment efficiency. Numerical optimization through a desirability function identified the formulations that best satisfied target criteria. Among four optimal check formulations, CF1 matched predicted values most closely, exhibiting a particle size of 102.3 nm, encapsulation efficiency of 93.5±1.36%, and a sustained drug release for up to 12 hours. To improve stability, the CF1 formulation was further lyophilized and incorporated into capsules, positioning it as a promising strategy for optimized Sorafenib delivery.

**Keywords:** Sorafenib tosylate, nanomicelles, Quality by Design (QbD), cancer theraphy, lyophilization

aishwaryabhandare1996@gmail.com

Tuberculosis (TB) is a global infectious disease caused by Mycobacterium tuberculosis, predominantly affecting the lungs. It remains a major public health concern, with a significant impact on morbidity and mortality worldwide. The standard treatment for TB involves a combination of antibiotics, and Rifampicin (RIF) is a key component of the first-line drug regimen. RIF is highly effective in killing the bacteria and shortening the treatment duration. However, its clinical utility is marred by several limitations, such as poor aqueous solubility, limited tissue penetration, and potential adverse effects. Additionally, the emergence of drug-resistant strains poses a significant challenge in TB management. In this research project, we aimed to address the limitations of Rifampicin by developing an innovative inhalable dry powder formulation. The formulation involved encapsulating RIF and HA (Hyaluronic Acid) in mixed micelles comprised of TPGS and Poloxamer 407 using the cold method. The mixed micelles system offers improved drug solubility, enhanced tissue penetration, and the potential to overcome drug resistance. We extensively evaluated the formulation for various physicochemical parameters, including particle size, entrapment efficiency, and zeta potential, to ensure its quality and stability. Our findings demonstrate the successful preparation of RIF-HA-P-MM dry powder, which exhibited excellent physicochemical attributes, including a spherical morphology and high entrapment efficiency. The sustained drug release over 8 hours and optimal aerodynamic properties further highlight its potential for targeted pulmonary delivery. This inhalable dry powder formulation represents a significant advancement in TB therapy, providing a more effective and precise drug delivery system. By overcoming the limitations of Rifampicin, our work holds immense importance in revolutionizing tuberculosis treatment, offering better patient outcomes, and contributing to the global efforts to combat this infectious disease.

**Keywords:** Polymeric mixed micelles, Dry powder, Encapsulation, Aerodynamic property.

## FORMULATION AND CHARACTERIZATION OF NANO-STRUCTURED LIPID CARRIERS FOR IMPROVED TOPICAL DELIVERY OF GABAPENTIN IN NEUROPATHIC PAIN MANAGEMENT

Vishal R. Gajbhiye, Amol A. Tatode, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra- 441002
Vish2891@gmail.com

Neuropathic pain remains a major clinical challenge due to limited efficacy and systemic side effects of conventional oral therapies. Gabapentin, a first-line drug for neuropathic pain, suffers from low bioavailability and requires frequent dosing, leading to patient non-compliance. In this study, Nano-Structured Lipid Carriers (NLCs) were designed and characterized to enhance the topical delivery of gabapentin. The NLCs were prepared using a hot homogenization–ultrasonication method, employing biocompatible solid and liquid lipids along with suitable surfactants. The formulations were evaluated for particle size, polydispersity index (PDI), zeta potential, entrapment efficiency, and morphology using dynamic light scattering and electron microscopy. Optimized NLCs exhibited particle size in the nanometer range (<200 nm), narrow PDI, high entrapment efficiency (>80%), and stable zeta potential. In-vitro drug release studies revealed a biphasic release profile with an initial burst followed by sustained release, while ex-vivo permeation studies across rat skin demonstrated significantly enhanced penetration compared to conventional formulations. Additionally, in-vivo evaluation in neuropathic pain models indicated improved analgesic efficacy and prolonged duration of action. The findings suggest that gabapentin-loaded NLCs can serve as a promising topical delivery system, offering site-specific action, reduced systemic exposure, and improved patient compliance in the management of neuropathic pain.

**Keywords:** Gabapentin, Nano-structured lipid carriers, Topical drug delivery, Neuropathic pain

## DEVELOPMENT AND EVALUATION OF LICORICE EXTRACT (GLYCYRRHIZA GLABRA) NANOPARTICLE-LOADED BUCCAL FILMS FOR TREATING ORAL MUCOSAL ULCERS BY APPLYING THE 32 FULL FACTORIAL DESIGN.

Rifaj Sarkar, Biswajit Basu, Anirbandeep Bose, Rajdip Goswami
Department of Pharmaceutical Technology, Adamas University, Kolkata, India-700126
rifajsarkar676@gmail.com

Oral mucosal ulcers represent painful inflammatory lesions and an enormous impact on patient's comfort and the quality of life. The current study aimed to formulate and assess the potential of licorice extract (Glycyrrhiza glabra) nanoparticle-loaded buccal films as a treatment system for treating oral ulcers. Nanoparticles were formulated to improve the solubility, stability, and bioavailability of the extract and then incorporated into the mucoadhesive buccal films. A $3^2$ full factorial design was used to systematically optimize formulation variables and study the effect of critical variables on mechanical strength, drug release, and mucoadhesion. The films were evaluated for their physical properties, in vitro drug release, and surface morphology. The optimized films showed more sustained release and bioadhesion, indicating the possibility of licorice-based nanoparticle-loaded buccal films with high potential to be a natural, non-toxic, patient-friendly therapeutic option.

**Keywords:** Licorice extract, Glycyrrhiza glabra, Buccal films, Nanoparticles, Oral ulcers, Factorial design.

Famotidine, a histamine $H_2$-receptor antagonist used for gastric ulcers, gastroesophageal reflux disease, and Zollinger–Ellison syndrome, often shows poor patient compliance due to conventional tablets with delayed onset of action. This study aimed to develop fast dissolving tablets (FDTs) of Famotidine using natural super disintegrants to enhance disintegration, dissolution, and bioavailability. Tablets were prepared by direct compression with Plantago ovata husk, banana powder, and fenugreek seed powder along with suitable excipients. The formulations were evaluated for weight variation, hardness, friability, wetting time, water absorption ratio, drug content, disintegration, and dissolution. Optimized tablets exhibited hardness of 3–4 kg/cm², friability below 1%, uniform drug content (98–101%), and disintegration within 20 seconds. Wetting time, water absorption ratio confirmed rapid water uptake, facilitating faster disintegration. In-vitro dissolution studies in simulated gastric fluid (pH 1.2) showed over 95% drug release within 15 minutes, compared to 62% from marketed tablets. The improved dissolution was attributed to the synergistic effect of natural disintegrants in enhancing breakup and wettability. Overall, the study confirms that natural super disintegrants are effective, economical, and biocompatible alternatives to synthetic ones in the formulation of Famotidine FDTs, offering faster onset of action, better compliance, and improved therapeutic efficacy.

**Keywords:** Famotidine, Fast dissolving tablets, Natural super disintegrants, Disintegration time, Dissolution.

kumar29599@gmail.com

ISBN: 978-81-980623-8-3

Diabetic wounds heal poorly due to rapid VHL-mediated degradation of HIF-1α, a key transcription factor regulating angiogenesis and tissue repair. Stabilizing HIF-1α by disrupting its interaction with VHL offers a promising therapeutic avenue. An integrated in-silico approach involving pharmacophore modeling, virtual screening, ADMET filtering, docking, MM-GBSA, and MD was employed to identify natural VHL inhibitors. To enhance delivery, hit molecule was co-formulated with metal oxide, into nanostructured lipid carriers (NLCs). NLCs were prepared via microemulsion method and optimized using Box–Behnken design, with particle size, zeta potential (ZP), and polydispersity index (PDI) identifed. Morphology, entrapment efficiency, and stability were assessed. PPI validation confirmed a strong VHL:HIF-1α interaction (score 0.999). Synephrine consistently showed favorable docking scores, low binding free energies, and stable MD trajectories, indicating effective blockade of the degradation interface. Optimized Synephrine–ZnO NLCs had a particle size of 113 nm, ZP +51 mV, and PDI 0.214, demonstrating excellent stability and narrow distribution. Entrapment efficiency was 82%, ensuring high drug loading. SEM and TEM revealed spherical, well-dispersed nanoparticles. Mechanistically, Synephrine is expected to preserve HIF-1α levels to restore angiogenic signaling, while ZnO provides antimicrobial action, oxidative stress reduction, and tissue regenerative support—together enhancing wound repair. An integrated in-silico to formulation approach successfully developed dual-drug (Synephrine–ZnO) loaded NLCs, was successfully optimized and characterized, representing a novel and targeted nanotherapeutic approach for diabetic wound healing.

**Keywords:** Diabetic wound, HIF-1α, VHL, Zinc oxide, NLC, Box-Behnken design.

## FORMULATION AND OPTIMIZATION OF LORNOXICAM LOADED NANOSTRUCTURE LIPID CARRIER GEL FOR TRANSDERMAL DRUG DELIVERY SYSTEM

Asawari Myakalwar, Shailendra Salvankar, Mukesh Ratnaparkhi, Rutuja Keluskar
Department of Pharmaceutics, Marathwada Mitra Mandal's College of Pharmacy, Pune-411033 (M.S.), India.
asawarimyakalwar@gmail.com

In this study, a nanostructured lipid carrier (NLC) gel of Lornoxicam (LNX) was developed as a novel and convenient transdermal drug delivery system to manage inflammation while minimizing the side effects associated with oral use. LNX-loaded NLCs were prepared by the ultrasonication method employing glyceryl palmitostearate as the solid lipid, cinnamon oil as the liquid lipid, Cremophor RH40 as the surfactant, and PEG 200 as the co-surfactant and penetration enhancer. The formulation was optimized using Central Composite Design (CCD) and incorporated into a poloxamer 407 gel base to obtain the final LNX-NLC gel. The optimized formulation was evaluated for skin irritation, anti-inflammatory activity, and ex-vivo skin permeation. Results indicated that the LNX-NLC gel showed significantly higher permeation across the skin compared to a conventional gel. It also exhibited strong anti-inflammatory activity, with better therapeutic effectiveness than oral treatment, and did not cause irritation to the skin. Overall, the study demonstrates that LNX-NLC gel is a promising transdermal nanocarrier for effective anti-inflammatory therapy. It provides enhanced drug permeation, improved efficacy, and reduced side effects compared to conventional formulations, making it a viable alternative to oral administration.

## FORMULATION AND EVALUATION OF ORODISPERSIBLE DOSAGE FORM OF NANOPARTICULATED ANTI ANGINAL DRUG

Bhanu N, K. Kavitha, Jancy K S
Department of Pharmaceutics, Nitte college of pharmaceutical sciences, Nitte (deemed to be university), Bengaluru-560064, Karnataka, India
bhanugowda1810@gmail.com

Amlodipine besylate (AB), a calcium channel blocker used for hypertension and chronic stable angina, exhibits poor water solubility resulting in compromised bioavailability and therapeutic efficacy. This study aimed to develop and evaluate amlodipine besylate nanoparticles using anti-solvent evaporation technique with multiple stabilizers including PVPK-30, Poloxamer-188, PVA, L-arginine and Tween-80 to enhance solubility and dissolution rate. Nanoparticles were characterized for particle size, drug entrapment efficiency and morphology using SEM, while tablets prepared by direct compression were evaluated against marketed formulations through in-vitro dissolution studies in 0.1N HCl and pH 6.8, with crystallinity changes assessed using DSC and XRD analysis. The formulated nanoparticles exhibited optimal size range (225.7-942.7 nm) with high drug entrapment efficiency (75-98%) and uniform, non-aggregated morphology. Dissolution studies demonstrated remarkable improvement with 99.3±1.37% drug release within 10 minutes compared to 21.9±0.21% from marketed tablets in both pH conditions. DSC and XRD analysis confirmed conversion from crystalline to amorphous form, enhancing dissolution kinetics and suggesting improved bioavailability. Hence, it can be concluded that the optimized formulation of Amlodipine besylate could improve the rate of absorption controlled by the rate of dissolution.

**Keywords:** Amlodipine besylate, nanoparticles, anti-solvent evaporation, bioavailability, dissolution enhancement

## DEVELOPMENT AND CHARACTERIZATION OF HERBAL HARD CANDY LOZENGES FOR PEDIATRICS

Santhosh Aruna Mamidi and Bachina Bhargav
Department of Pharmaceutical Sciences-SIMS College of Pharmacy,Guntur,Andhra Pradesh, India-522001.
bachinabhargav000@gmail.com

The current research centers on the development, and evaluation of herbal lozenges targeted at pediatric use for managing cough and sore throat, utilizing the therapeutic benefits of Licorice (Glycyrrhiza glabra), Tulsi (Ocimum sanctum), and Ginger (Zingiber officinale) powders. The choice of these herbs is based on their established antimicrobial, anti-inflammatory, expectorant, and soothing properties, aiming to provide a safer, more palatable alternative to conventional chemical lozenges, which often pose challenges related to taste, side effects, and compliance in children.The lozenges were formulated using the fusion method, with jaggery as a natural base, honey as a sweetener and binder, and lemon as a flavoring agent to enhance acceptability and therapeutic efficacy. The preparation involved accurately weighing and blending the herbal powders, melting jaggery, adding honey, incorporating the herbal blend, and finally mixing in fresh lemon juice before molding and cooling. Each step aimed to preserve the integrity of the active compounds and ensure uniformity in the final product. Results indicated that the formulated lozenges possessed excellent organoleptic properties, described as glossy, golden brown, with a pleasant herbal aroma, sweet and slightly spicy taste, and smooth, hard texture—ensuring child acceptability. Physical evaluation showed uniform weight (3.19 g3.19g), hardness within the ideal range (3.5–4.0 kg/cm23.5–4.0kg/cm2), low friability (0.63%0.63%), rapid disintegration (9.15 min9.15min), and pH suitable for oral use (6.3–6.56.3–6.5). Moisture content averaged 5.55%5.55%, well below the maximum threshold for lozenge formulations, ensuring stability and safety. Accelerated stability studies over three months revealed no significant changes in physical appearance, taste, or technical attributes, with all parameters remaining within acceptable pharmacopoeial limits.

**Keywords:** Lozenges, Expectorant, Fusion Method, Herbal

## DESIGN AND DEVELOPMENT OF FAST DISSOLVING TABLETS OF ACECLOFENAC

Chowdari Mahesh and V.Saikishore
Department of Pharmaceutics, Bapatla College of Pharmacy, Bapatla-522101
maheshchowdari022@gmail.com

In the current research, the effect of different hydrophilic carriers on the solubility and dissolution rate of Aceclofenac were studied by spherically agglomeration technique. Spherical agglomerates were prepared by using N, N-dimethyl formamidel, water and chloroform as good solvent, poor solvent and bridging liquid, respectively. The quasi-emulsion solvent diffusion technique was used as a method for spherical

ISBN: 978-81-980623-8-3

agglomeration. Spherical agglomeration of Aceclofenac were prepared by using h HPMCE5, h HPMCE15, Polyethylene glycol-6000 and PVP k-30 as water soluble carries proportions like 1:0.5,1:0.75,1:1. The agglomerates were subjected to various physicochemical evaluations such as practical yield, drug content, solubility, flow properities, average particle size,scanning electron microscopy and dissolution studies. The optical electron microscopy studies showed that the agglomerates posseeses a good spherical shape. This study, demonstrated that the successful development of directly compressible spherical agglomerates of Aceclofenac prepared with hydrophilic polymers enhances the in-vitro dissolution property of Aceclofenac, whichcould provide rapid onset of action and potentially increases oral bioavailability.The dissolution rate of Aceclofenac was found to be affected by nature of the superdisintegrant used in the preparation of tablets. Based on the dissolution rate, natural superdisintegrants can be rated as Banana powder < Dry mushroom powder < Modified Gum karaya. The formulation prepared with Modified Gum karaya was offered relatively rapid release of Aceclofenac when compared with other superdisintegrants used in this investigation.

**Keywords:** Aceclofenac, Spherical Agglomerates, Emulsion solvent diffusion, Modified Gum karaya

**PC-73**

## FAST DISSOLVING ORAL THIN FILMS, A NOVEL DOSAGE FORM FOR ENHANCED DRUG DELIVERY

Mahalaksmi Chittimalla*, Suvarna Aladakatti, Krishna Mohan Chinnala
Department of Pharmaceutical Sciences, School of Pharmacy
Nalla Narasimha Reddy Education Society's Group of Institutions,
Hyderabad, Telangana, INDIA
maharamesh.004@gmail.com

This study aimed to design and characterize rapidly disintegrating oral thin films incorporating eletriptan, a frontline therapeutic agent for migraine treatment. Oral thin films represent a novel dosage forms recognized for their ability to dissolve quickly in the oral cavity, eliminate the need for water, and improve overall patient compliance. Films were fabricated using the solvent casting technique with hydroxypropyl methylcellulose (HPMC E15), maltodextrin, and suitable excipients to achieve optimal film-forming properties. The formulations were systematically evaluated for their physicochemical and pharmaceutical attributes, including thickness uniformity, folding endurance, surface pH, morphology, tensile strength, elongation capacity, drug loading accuracy, disintegration time, and dissolution behavior. Among the prepared batches, formulation F7 containing HPMC E15 demonstrated superior characteristics, exhibiting a rapid disintegration time of approximately 10 seconds, high dissolution efficiency with nearly complete drug release nearly 98% within 20 minutes, and favorable stability under storage conditions. Comparative assessment against the pure drug confirmed enhanced dissolution, suggesting improved bioavailability. Overall, the results underscore the potential of fast-dissolving oral thin films as a patient-friendly and efficient delivery system for migraine management, ensuring a faster onset of therapeutic action along with higher treatment convenience.

**Keywords:** Oral thin film, Solvent casting method, Eletriptan, HPMC

## DESIGN AND EVALUATION OF MICROCAPSULES OF NONSTEROIDAL ANTI-INFLAMMATORY DRUG FOR COLON SPECIFIC DRUG DELIVERY

Swapna K Y, K Kavitha and Sangeetha N
Department of Pharmaceutics, Nitte college of pharmaceutical sciences , Nitte (deemed to be university), Bengaluru -560064, Karnataka , India
Swapnanaidunaidu12@gmail.com

This study focused on creating and assessing a colon-targeted, pulsatile conveyan framework for Flurbiprofen (FP), a non-steroidal anti-inflammatory medicate (NSAID) characterized by a brief half-life that requires customary organization. To handle this issue FP-loaded microcapsules were made utilizing pH-sensitive polymers Eudragit RS/RL-100 through the emulsion dissolvable dissipation strategy. The entirety framework was coated with 5% cellulose acetic acid derivation phthalate (CAP) to give resistance to stomach conditions and encourage discharge in the colon. The characterization of FP microcapsules included IR, SEM, DSC, molecule measure examination, sedate substance evaluation entanglement productivity assessment and in vitro disintegration testing. The discharge of FP was kept up and essentially administered by dissemination, adjusting best with zero-order and Higuchi models and shown a non-Fickian discharge component concurring to Korsmeyer-Peppas examination. Raising the sum of hydrogel polymer come about in a drawn out slack time and delayed sedate discharge approving programmable conveyance. The discharge characteristics of optimized definitions were comparable to those of a commercial item. In this study can be concluded that chronotherapeutic, colon-targeted pulsatile conveyance component, able to discharge FP in a controlled mold amid a 2–24 hour time allotment comparing with circadian cycles noteworthy in conditions such as arthritis.

**Keywords:** Pulsatile, Colon-targeted gadget, Chronotherapy, Circadian cycle, Flurbiprofen.

## DESIGN AND CHARACTERIZATION OF PULSATILE DRUG DELIVERY OF TRAMADOLOL HYDROCHLORIDE

Shaik Munwar Sulthana, M. Sukanya and V.Saikishore
Department of Pharmaceutics,Bapatla College of Pharmacy, Bapatla-522101
msulthanashaik@gmail.com

In the present study, an effort was made to develop the pulsatile drug delivery of Tramadol hydrochloride to the colon. A time delayed capsule was prepared by sealing the microspheres inside the insoluble hard gelatin capsule body with erodible hydrogel plug. The microspheres were prepared by emulsion solvent evaporation technique... Optimized microsphere formulations were selected based on dissolution studies. The entire device was enteric coated, so that the variability in gastric emptying time can be overcome and a colon-specific release can be achieved. Hydrogel plug (HPMCK100 and lactose in 1:1 ratio) having 4.5kg/cm2 hardness and 100 mg weight was placed in the capsule opening and found that it was satisfactory to retard the drug release in small intestinal fluid and to eject out the plug in colonic fluid and releasing the microspheres into colonic fluid after a lag time criterion of 5 hours. In order to simulate the pH changes along the GI tract, three dissolution media with pH 1.2, 7.4 and 6.8 were sequentially used. FTIR study confirmed that there was no interaction between drug and polymer. Among all the formulations Tramadol hydrochloride microspheres prepared with Eudragit RL 100 in 1:2 ratio shown prolonged release for a period of 12 hours. The obtained results revealed the capability of the system in delaying drug release for a programmable period of time and can prevent a sharp increase in the blood pressure during the early morning hours, a time when the risk of hypertension is the greatest.

## FORMULATION AND EVALUATION OF BUCCAL TABLETS OF FELODIPINE BY USING NATURAL POLYMERS

Vinayaka T Muganavar, Lokesh R, Harsha shivappa
Aditya Bangalore Institute of Pharmacy Education and Research
muganavarvinayaka@gmail.com

The main aim of the present study was to formulate and evaluate buccal tablets for buccal drug delivery of Felodipine by using natural polymer in order to overcome bioavailability related problems and reduce dose-dependent side effects. Different five formulations of buccal tablets were prepared by using Xanthan gum as natural polymer in different concentrations by the direct compression method. The prepared buccal formulations were evaluated for various parameters like physical appearance, thickness, swelling index, surface pH, mucoadhesive strength, drug content, weight uniformity, in-vitro drug dissolution, and stability studies. The swelling index was proportional to the polymer content. The surface pH of all tablets was found to be satisfactory, i.e., close to neutral pH; hence, buccal cavity irritation should not occur with these tablets. The drug release and diffusion from the buccal tablets depends on the concentration and type of polymer used in the formulation. From the in-vitro drug release study, it was found that formulation F3 has a good drug release of 96.40% when compared to other formulations. The formulation F3, containing Felodipine and Xanthan gum as natural polymer, is the optimised formulation. Overall, buccal tablets were successfully prepared for Felodipine, and their

ISBN: 978-81-980623-8-3

evaluation suggested excellent quality and uniformity in tablet characteristics.

**Keywords:** Felodipine, Buccal tablet, Direct compression method, Natural polymer like Xanthan gum and Chitosan as penetration enhancers

**FORMULATION AND EVALUATION OF OCULAR IN- SITU GEL OF NORFLOXACIN BY USING NATURAL POLYMERS**

Sangeetha N, K Kavitha, Swapna K Y
Department of Pharmaceutics, Nitte college of pharmaceutical sciences, Nitte (deemed to be university), Bengaluru -560064, Karnataka, India
sangeethasangeetha00417@gmail.com

Conventional ocular drug delivery through eye drops is hindered by rapid nasolacrimal drainage and limited residence time, leading poor bioavailability. In situ gels, capable of reversible sol–gel transition, enhance drug retention and absorption. The present study aimed to formulate ocular in situ gels of Norfloxacin using chitosan and poloxamer for bacterial infections. Six formulations were prepared by pH and temperature dependent gelation with varying chitosan concentrations. The gels were evaluated for clarity, pH, drug content, gelling capacity, viscosity, sterility, in vitro drug release, ocular irritation, antimicrobial activity, and stability. All formulations were transparent, uniform, and exhibited physiological pH (7.1–7.4). Drug content was 92–98%, with FTIR confirming no drug–polymer interaction. Rheological analysis showed pseudoplastic flow. In vitro release studies demonstrated sustained Norfloxacin release more than 8 hours, with maximum 98%. Higher chitosan concentrations decreased release rate, indicating controlled delivery. Kinetic modeling revealed first-order, diffusion-controlled, and non-Fickian release. Antimicrobial tests confirmed effective bacterial inhibition, ocular irritation studies showed non-irritancy. Stability studies demonstrated good physical, chemical stability under room and accelerated conditions. The findings suggest that Norfloxacin in situ gels prepared with chitosan and poloxamer are safe, stable, and effective, offering sustained ocular delivery, improved bioavailability, and enhanced therapeutic efficacy.

**Keywords:** Chitosan; in situ gels; ocular delivery; bioavailability; antimicrobial

**DEVELOPMENT AND CHARACTERISATION OF CONTROLLED RELEASE TRAMADOL HYDROCHLORIDE MICROPARTICLES LOADED TOPICAL GEL FOR EFFECTIVE PAIN MANAGEMENT**

Jancy KS, K. Kavitha, Bhanu N
Department of Pharmaceutics, Nitte college of pharmaceutical sciences, Nitte (deemed to be university), Bengaluru-560064, Karnataka, India
ksjancy1523@gmail.com

The present study aimed to develop a topical gel containing Tramadol Hydrochloride microspheres as a site-specific vesicular carrier using chitosan as a natural biopolymer. Microspheres of Tramadol Hydrochloride were prepared by the ionic gelation method employing sodium tripolyphosphate (Na-TPP) as the crosslinking agent and chitosan as the polymer, and the formulations were characterized for compatibility by FTIR, surface morphology by SEM, particle size distribution, entrapment efficiency, in vitro drug release, and release kinetics. The optimized microsphere batch was incorporated into a chitosan gel base by simple dispersion to prepare both plain Tramadol gel and Tramadol micro-based gel, which were evaluated for clarity, pH, drug content, spreadability, viscosity, in vitro diffusion, skin irritation, analgesic, and anti-inflammatory activity. FTIR confirmed the absence of drug–polymer interaction, while SEM analysis revealed smooth-surfaced microspheres at higher polymer concentrations. The ionic gelation method achieved a maximum entrapment efficiency of 89%, and drug release showed an initial burst followed by sustained release governed by Fickian diffusion. Among the prepared gels, the Tramadol micro-based gel exhibited superior drug release, diffusion, and pharmacological activities compared with the plain gel. The study concludes that Tramadol micro-based gel can enhance clinical efficacy through transdermal delivery by bypassing first-pass metabolism and reducing opioid-like side effects, while incorporation of permeation enhancers may further improve bioavailability and therapeutic potential.

**Keywords:** Tramadol Hydrochloride, Chitosan, Microspheres, Ionic Gelation, Topical Gel, In vitro Release

**FABRICATION AND EVALUATION OF BILAYERED FILMS OF DULOXETINE HYDROCHLORIDE FOR BUCCAL DRUG DELIVERY**

Padala Narayana Raju, P. Sravanthi, V. Bhaskara Raju and P.Sri Harshitha
Sri Vasavi Institute of Pharmaceutical Sciences, Pedatadepalli, Tadepalligudem - 534 101. West Godavari Dist., Andhra Pradesh.
nrpadala@gmail.com

The aim of the present study was to formulate and evaluate muccoadhesive bilayered films of Duloxetine hydrochloride by using bioadhesive polymers. Duloxetine hydrochloride is a serotonin–norepinephrine reuptake inhibitor (SSNRI) indicated for the treatment of depression. Duloxetine suffers from reduced oral bioavailability (50%) due to hepatic metabolism.This study aims to develop Duloxetine bucco-adhesive films to improve its bioavailability and to obtain a controlled release of drug throughout the oral cavity. Duloxetine buccoadhesive films were prepared adopting the solvent casting method using hydroxypropyl methylcellulose (HPMC E5 and E15) and with combination of chitosan. The prepared drug loaded films are attatched to a backing layer (HPMCP) to enable unidirectional drug delivery. The prepared films were evaluated for weight uniformity, drug content, folding endurance, surface pH, and In-vitro dissolution studies. The surface pH of all the formulations was found around 6.4 for all the formulations. The drug content for all the formulations of HPMC-Chitosan was found to be 96-99 %. The muco adhesion time was found to be 130-310 minutes for the formulation prepared with HPMC E15-chitosan. The in vitro drug release with combination of HPMC E 5-chitosan extended the drug release up to 8 to 11 hrs and for HPMCE15-Chitosan extended the drug release up to 7 -12 hrs. The muco adhesion time was found to be 130-310 minutes for the HPMC E15-chitosan films and for HPMCE5-Chitosan was found to be 100 to 270 minutes. DSC and FTIR study showed no drug polymer interaction. Therefore, the prepared buccal films offer an alternative route for the administration of duloxetine with the possibility of improving its bioavailability.

**Keywords:** Duloxetine, Buccal films, HPMC-Chitosan, Solvent casting

**FORMULATION AND EVALUATION OF HERBAL EMULGEL CONTAINING HYPERICUM PERFORATUM LEAF EXTRACT**

D. Chinnari*, N. Swapna, C. Krishna Mohan
Department of Pharmaceutics, School of Pharmacy, Nalla Narasimha Reddy Education Society's Group of Institutions, Hyderabad, Telangana, India – 500 088.
estherdevarampati@gmail.com

In this study emulgel was formulated using Hypericum perforatum leaf extract. Polymers like sodium carboxy methyl cellulose ,carbopol 974P and xanthan gum were used as gelling agents in various proportions. Liquid paraffin was used as oil phase and a combination of Span 80 and Tween 80 were used as emulsifying agents. Various formulation were prepared by changing the gelling agent and their concentration. The prepared emulgels were evaluated for physical appearance, pH, spreadability co efficient, physical stability, drug content and in-vitro drug release. The formulations were found to have good homogeneity, consistency, no phase separation. The pH of formulation was found to be in the range of 6.18-6.58. The drug content was found to be in the good range indicating uniform distribution of drug. All the formulations have shown good spreadability coefficient. In-vitro diffusion studies were carried out using phosphate buffer and good drug release was shown by F3 formulation.

**Keywords:** Emulgel, Hypericum perforatum, Carbopol, Xanthan gum.

**DESIGN AND PSEUDOTERNARY PHASE DIAGRAM OF A GALLIC ACID-BASED NANO-EMULGEL FOR TOPICAL DELIVERY IN ATOPIC DERMATITIS**

M S Champashree, Deepthi Swapna P R, M Pharm, (Ph.D.) Associate Professor
Department of Industrial Pharmacy, Aditya Bangalore Institute of Pharmacy Education and

ISBN: 978-81-980623-8-3

Research, Bangalore, Karnataka, India–560064.
champashreemschampa@gmail.com

Gallic acid is a natural polyphenol with potent antioxidant and antibacterial properties but limited topical bioavailability due to poor permeability and instability. This study aimed to design and pseudoternary phase diagram of a gallic acid-based nano emulgel for topical delivery in atopic dermatitis. A pseudoternary phase diagram is a triangular plot used to map the composition ranges of oil, surfactant/cosurfactant mixture (Smix), and water that form stable nanoemulsion regions. Nanoemulsions were formulated using oleic acid or isopropyl myristate (oil phase), Tween 80/20 (surfactant), and glycerin, propylene glycol, or PEG (cosurfactant). Pseudoternary phase diagrams were constructed by aqueous titration of oil–Smix mixtures at various Smix ratios (1:1, 2:1, 3:1, and 4:1) and oil:Smix ratios ranging from 1:9 to 9:1 to identify nanoemulsion regions. Aqueous titration was carried out by slowly adding distilled water to mixtures of oil and Smix under continuous stirring to observe the point at which a clear and stable nanoemulsion forms. The constructed pseudoternary phase diagrams successfully identified stable nanoemulsion zones, providing a systematic basis for developing an optimized gallic acid–loaded nanoemulgel with improved topical bioavailability.

**Keywords:** Gallic acid, nano-emulgel, atopic dermatitis, topical delivery, pseudoternary phase diagram, aqueous titration.

## FORMULATION AND EVALUATION OF PLGA-BASED BIODEGRADABLE MICROSPHERES FOR SUSTAINED DELIVERY OF RIVASTIGMINE HYDROGEN TARTRATE

Uday Akarte, Neha Raut, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee
akarteuday@gmail.com

The present study focuses on the formulation, development, and evaluation of biodegradable Microspheres using poly(lactic-co-glycolic acid) (PLGA) as a polymeric carrier for the Sustained delivery of Rivastigmine hydrogen tartrate, a cholinesterase inhibitor used in the Treatment of Alzheimer's and Parkinson's disease-associated dementia. The goal was to Enhance therapeutic efficacy, reduce dosing frequency, and improve patient compliance Through a controlled drug release approach. PLGA was selected over other polymers such as Hydroxypropyl methylcellulose (HPMC) and ethyl cellulose (EC) due to its unique Advantages—particularly its biodegradability, biocompatibility, regulatory acceptance, and Ability to provide tunable drug release profiles. Unlike EC, which is non-degradable, or HPMC, Which often leads to short-term release, PLGA degrades into metabolically inert byproducts And allows precise control over release duration through adjustment of its lactide- to-glycosideRatio and molecular weight. Microspheres were prepared using the solvent extraction method, With dichloromethane as the organic solvent and polyvinyl alcohol (PVA) as a stabilizer. Preformulation studies included solubility testing, UV-visible spectrophotometric calibration, And drug characterization. Several batches were formulated by varying concentrations of PLGA And other excipients to optimize encapsulation efficiency and release kinetics. The developed Microspheres were evaluated for appearance, pH, viscosity, and in vitro drug release using a Modified Franz diffusion cell. Results confirmed uniform microsphere formation with desirable Sustained-release behavior. Stability studies under ICH guidelines supported the formulation's Robustness. Stability studies of the microsphere formulation were conducted under various Conditions, including room temperature (25 ± 2 °C), hot air oven (50 ± 2 °C), refrigeration (2–8 °C), and deep refrigeration (0 to –4 °C). The formulation was monitored for physical and Chemical stability across all storage environments. Results indicated that the microsphere Formulation remained stable and successfully passed all stability tests. Overall, PLGA emerged As a superior polymer for long- acting injectable microsphere formulations.

**Keywords:** Biodegradable microspheres, Sustained drug delivery, Rivastigmine hydrogen tartrate, Alzheimer's disease, Parkinson's disease-associat, Polyvinyl alcohol (PVA), Encapsulation efficiency, Franz diffusion cell, Biocompatibility

## INTRANASAL CHIA SEED OIL NANOEMULSION OF FLUOXETINE: A NOVEL APPROACH FOR NOSE-TO-BRAIN DELIVERY IN DEPRESSION

Pratiksha Chavan, Shailendra Salvankar, Mukesh Ratnaparkhi, Kshitij Walke
Department of Pharmaceutics, Marathwada Mitra Mandal's College of Pharmacy, Pune-411033 (M.S.), India.
chavanpratiksha085@gmail.com

The present study focused on the development of a chia seed oil (CSO)-based nanoemulsion (NE) of Fluoxetine Hydrochloride (FLX-HCL) for intranasal delivery to enhance nose-to-brain targeting in depression therapy. CSO was chosen as the oil phase owing to its high alpha-linolenic acid content (67.8%) and permeability-enhancing properties. Solubility studies demonstrated maximum solubility of FLX in CSO (10 ± 1.4 mg/mL). Pseudo-ternary phase diagrams revealed a Smix ratio of 2:1 (surfactant:cosurfactant) as optimal, with the batch (5% oil, 45% Smix, 50% water) selected for further evaluation. The optimized NE exhibited droplet size 84.17 to 86.71 nm, PDI 0.258 and 0.271, zeta potential -8.15 to -8.21 mV, transmittance 97%, drug content 87.58 to 88.21%, In vitro release showed sustained drug release of 98.62 ± 1.3% within 8 hours, following Korsmeyer-Peppas kinetics ($R^2$ = 0.9944, n = 1.164). Ex vivo permeation across sheep nasal mucosa revealed 95% drug diffusion in 4 hours with higher flux (20.91 ± 0.17 µg/cm²/h) compared to FLX solution (17.96 ± 0.024 µg/cm²/h).TEM confirmed spherical droplets (15–50 nm), while histopathology demonstrated no mucosal toxicity. Pharmacodynamic studies in Wistar rats indicated enhanced antidepressant efficacy of FLX-NE.Thus, CSO-based FLX-NE is a safe intranasal system for targeted brain delivery in depression management.

**Keywords:** Fluoxetine Hydrochloride, Chia seed oil, Nanoemulsion, Nose-to-Brain Delivery Depression.

**PC-84**

## FORMULATION AND EVALUATION OF GASTRO-RETENTIVE DRUG DELIVERY SYSTEM OF CILNIDIPINE

T.N.Rakshitha, K.Sweatharenya, M.Kirubhagaran, A.Bhagavathy
Department of Pharmaceutical Sciences, Ultra College Of Pharmacy, Madurai, Tamilnadu -625020.
rakshasuresh99@gmail.com

Cilnidipine's low oral bioavailability (~13%) and short half-life (~2.5 h) motivate a gastro-retentive system to sustain exposure. Objective: To develop and evaluate effervescent floating tablets using HPMC K4M and Carbopol 934 with sodium bicarbonate–citric acid. Methods: Four batches (F1–F4) were fabricated by dry granulation; evaluated for physical quality, buoyancy, drug content, and in-vitro release in 0.1 N HCl; release kinetics via Higuchi and Korsmeyer–Peppas; accelerated stability of the optimized batch at 40 °C/75% RH for one month. Results: All met pharmacopeial limits, showed floating lag time ≤20 s and >10 h total float, and drug content >97%. F3 (HPMC K4M 80 mg; Carbopol 934 35 mg) achieved 96.4% release at 10 h, while higher polymer loading (F4) slowed release to 83% at 10 h. Kinetic analysis indicated non-Fickian (0.45<n<0.89) release. Overall stability confirmed minimal changes in appearance, buoyancy (~9 h 40 min), assay (~99%), and dissolution (~95%). Tablets met hardness and friability criteria. FTIR spectra showed no drug–excipient incompatibility. F3's floating lag time was ~10.5 s. In-vitro data fit first-order kinetics best for F3 ($r^2$≈0.996). Conclusion: Effervescent floating cilnidipine tablets were successfully developed; the optimized F3 batch combined rapid buoyancy, sustained ten-hour release, and stability, supporting improved gastric residence, bioavailability, adherence, and patient convenience in hypertension therapy.

**Keywords:** Cilnidipine, floating tablets, Effervescent system, HPMC K4M, Carbopol 934, Gastroretentive delivery.

## DESIGN, DEVELOPMENT AND LIPOSOMAL DRUG DELIVERY FOR BRAIN DISORDERS USING BOX-BEHNKEN DESIGN

Mrs. P M M Naga Lakshmi Varma, Dr. J. Subba Rao
Research Scholar, Department of Pharmaceutics, Acharya Nagarjuna University.
Associate Professor, HOD, Department of Pharmaceutical Chemistry, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences.
nagapmm285@gmail.com

ISBN: 978-81-980623-8-3

Oxcarbazepine is an antiepileptic drug used primarily for the treatment of partial and generalized seizures. It acts by stabilizing hyperexcited neuronal membranes and inhibiting repetitive neuronal firing. Despite its effectiveness, Oxcarbazepine has limited brain bioavailability due to poor permeability across the blood-brain barrier. Advanced drug delivery systems, such as liposomes, are being explored to enhance its CNS targeting. In this study, a liposomal drug delivery system for Oxcarbazepine was developed and optimized using the Box-Behnken Design (BBD), a response surface methodology approach, to overcome these limitations. Three key formulation variables—phospholipid concentration, cholesterol content, and drug-to-lipid ratio—were selected as independent factors, while encapsulation efficiency (%EE), particle size (nm), and cumulative drug release over 24 hours (%CDR) were evaluated as dependent responses. BBD generated 17 experimental runs, and statistical analysis confirmed a significant quadratic model ($p < 0.05$) for all responses. The optimized liposomal formulation exhibited an encapsulation efficiency of 86.2%, particle size of 139.6 nm, zeta potential of –27.1 mV, and 24-hour cumulative drug release of 74.3%, indicating efficient encapsulation, colloidal stability, and sustained release. Transmission electron microscopy revealed uniform, spherical vesicles. Oxcarbazepine liposomes offer a promising strategy for targeted and sustained delivery in the management of epilepsy and related brain disorders. Further In-vivo studies are recommended for therapeutic purpose.

**Keywords:** Oxcarbazepine, Box-Behnken Design, Transmission electron microscopy.

## FORMULATION AND EVALUATION OF FAST-ORAL DISSOLVING ORAL FILMS OF OXCARBAZEPINE FOR EPILEPSY

Pranitha D B, Suhas Gowda P, Prakash S Goudanavar, Bhoomika
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Soladevanahalli, Bengaluru, Karnataka, India – 560107
bhoomikaadoor85@gmail.com

Development and evaluation of Oxcarbazepine, an anticonvulsant drug used for the treatment of epilepsy, as a fast-dissolving oral film are the primary goals of this research. Oral films were formulated by the solvent casting technique with hydroxypropyl methylcellulose (HPMC E5) as film-forming polymer, polyethylene glycol 400 as plasticizer, and different super disintegrants such as sodium starch glycolate, croscarmellose sodium, and crospovidone. Mechanical properties, thickness, weight variation, folding endurance, drug content, and moisture content of the films were determined. Compatibility was evaluated by differential scanning calorimetry (DSC) and Fourier-transform infrared spectroscopy (FTIR). In vitro dissolution and disintegration were performed in phosphate buffer solution (pH 6.8). Mechanical strength studies confirmed that all the formulations had adequate folding resistance and tensile stability. FTIR spectra and DSC thermograms showed no appreciable drug-excipient interactions and proved that the oxcarbazepine was stable in the polymer matrix. Disintegration test results showed that the films disintegrated rapidly between 4 and 15 seconds, varying based on the super disintegrant. Dissolution tests indicated that while other formulations exhibited relatively slower release rates, films prepared with crospovidone delivered the highest drug release, which was above 90% within 20 minutes. Fast-dissolving oral films of oxcarbazepine that were formulated with crospovidone as a disintegrating agent had excellent dissolution performance, rapid disintegration, and optimal mechanical strength. By offering a more patient-friendly alternative to conventional tablets, these films enhance therapeutic efficacy and compliance, especially for pediatric and geriatric patients with difficulty swallowing.

**Keywords:** Fast dissolving-oral films, oxcarbazepine, super disintegrant, differential scanning calorimetry, FTIR

## FORMULATION AND EVALUATION OF POLYMERIC NANO MICELLES CONTAINING AN ANTI CANCER AGENT

Harsha Shivappa, Lokesh R, Vinayaka T M
Aditya Bangalore Institute of Pharmacy Education and Research
Shivappaharsha123@gmail.com

This study was undertaken to develop nanomicelles encapsulating Sorafenib tosylate using a Quality by Design (QbD) approach, aiming to enhance oral drug delivery and performance. Nanomicelles were fabricated via a dry-down (evaporation) method, and a definitive screening design was employed to evaluate the effect of key formulation and process variables, including drug amount, drug-to-polymer ratio, polymer-to-polymer ratio, types and ratios of polymer and stabilizer, as well as sonication settings. The primary response variables were particle size and entrapment efficiency. Entrapment efficiencies ranged from 80.2±3.81% to 96.83±4.12%, while particle sizes varied between 101.2 nm and 190.5 nm, accompanied by polydispersity index values of 0.203 to 0.345. In vitro drug release profiles were best described by the Korsmeyer- Peppas kinetic model, with "n" values between 0.5847±0.054 and 0.7311±0.077, indicating non-Fickian (anomalous) diffusion as the main release mechanism. The amount of drug demonstrated a significant positive impact on particle size and a negative impact on entrapment efficiency. Numerical optimization through a desirability function identified the formulations that best satisfied target criteria. Among four optimal check formulations, CF1 matched predicted values most closely, exhibiting a particle size of 102.3 nm, encapsulation efficiency of 93.5±1.36%, and a sustained drug release for up to 12 hours. To improve stability, the CF1 formulation was further lyophilized and incorporated into capsules, positioning it as a promising strategy for optimized Sorafenib delivery.

**Keywords:** Sorafenib tosylate, nanomicelles, Quality by Design (QbD), cancer theraphy, lyophilization

## DOE BASED OPTIMIZATION AND QUALITY CONTROL EVALUATION APPROACH FOR THE DEVELOPMENT OF HERBAL FORMULATION

Manasi Mulik1, Shubham Thube, Ashwin Kuchekar, Chandrakant More, Ganesh Choudhari
School of Health Sciences and Technology, Dr. Vishwanath Karad MIT World Peace University, MIT Campus, Kothrud, Pune - 411038, Maharashtra, India.
Shri Swami Samarth Ayurvedic Pharmaceuticals, Trimbakeshwar, Dist. Nashik-422212, Maharashtra, India
mansimulik08@gmail.com

Type 2 Diabetes mellitus is a prevalent condition affecting 10.5% of the global population aged between 20 to 79 years. The increasing inclination towards herbal medications is driven by their fewer adverse effects compared to synthetic drugs. Herbal medications present a viable alternative for Type 2 Diabetes mellitus treatment, with Curcuma longa and Salacia chinensis recognized for their anti-diabetic properties due to their inhibition of α-glucosidase, which reduces glucose levels in the bloodstream. Literature review indicates no prior research on the combination of Curcuma longa and Salacia chinensis. Therefore, this study aims to develop a herbal formulation containing extracts of these two herbs using the DoE (Design of Experiments) approach. To address issues of instability under environmental conditions and the bitter taste of herbal compounds, microencapsulation was employed. Organoleptic properties and phytochemical screening of Curcuma longa and Salacia chinensis extracts were conducted. The herbal microcapsules were formulated with these extracts for treating Type 2 Diabetes mellitus, applying DoE with the Design Expert software version 13, using a central composite design model. Nine experimental runs were generated, and for each batch, drug content and cumulative drug release were observed as responses. Sodium alginate and calcium chloride were selected as factor A and factor B (input parameters). Optimization and analysis of the data from DoE revealed batch 3 as the most promising. Flow properties, drug entrapment efficiency, and dissolution study using the USP type 2 dissolution test apparatus were performed for the optimized batch. The marker compounds Curcumin (CUR) and Mangiferin (MAN) in Curcuma longa and Salacia chinensis showed maximum absorbance at 426 nm and 254 nm, respectively. Cumulative drug release and drug content were assessed by UV spectrophotometer. HPTLC analysis of raw materials and formulation was conducted, with methods developed and validated according to ICH guidelines. Solubility, moisture content, and organoleptic properties were evaluated. DSC studies of the optimized batch were performed. In-vitro antioxidant and antidiabetic evaluations of extracts and formulation were carried out using DPPH, α-amylase inhibitory assay, and glucose uptake assay of the optimized batch.

## PREPARATION AND STATISTICAL OPTIMIZATION OF AMLODIPINE BESYLATE MICROSPHERES VIA 3-FACTOR–3-LEVEL BOX–BEHNKEN DESIGN

Priyasa Dutta, Suvendu Kumar Sahoo, Rabinarayan Parhi
Department of Pharmaceutical Technology, School of Health and Medical Sciences, Adamas University, Barasat, Kolkata - 700126, West Bengal, India.
priyasadutta26@gmail.com

Amlodipine besylate, a calcium-channel blocker, is clinically administered for hypertension, however, plasma level fluctuation and side reaction often occur by the usual formulation. The objective of this study was to prepare sustained release amlodipine besylate-loaded microspheres and optimize its formulation employing 3-factor, 3-level Box-Behnken design. Microspheres were obtained by W/O single emulsion solvent evaporation with the use of Drugcoat® RLPO for the polymer, and Span 80 for surfactant. The factors investigated were the drug-to-polymer ratio, the concentration of surfactant, and the quantity of acetone, whereas the responses were entrapment efficiency (EE) and cumulative percentage release of drug (CPR). The yield varied from 72.47 to 92.17% and microspheres were dominantly spherical with low porosity (10–100 µm). Polynomial equations suggested an increase in Span 80 increased EE and CPR whereas that of Drugcoat* RLPO decreased the same. Optimized formulation (drug polymer ratio 1:1.53, 0.1% surfactant, 3.99 ml acetone) exhibited 85.12% of EE, 86.76% of CPR up to 12 h in the release mode mechanism of Fickian diffusion. These findings further support the usefulness of Box-Behnken design as an effective tool for optimizing amlodipine microsphere formulation toward controlled drug release.

**Keywords:** Box-Behnken design, Amlodipine microsphere, Drugcoat® RLPO, Entrapment efficiency, Controlled release

## PHARMACEUTICAL TECHNOLOGY

Kappa gayatri
Department of Pharmaceutical Sciences, MAM College of Pharmacy, Kesanupalli, AP, India-522601
Gayatrireddy866@gmail.com

Pharmaceutical technology is a multidisciplinary field that focuses on the development, production and quality control of medications. It combines principles of chemistry, biology, engineering and material science to ensure that drugs are safe, effective and produced consistently. The core areas of pharmaceutical technology include drug formulation, manufacturing processes, drug delivery systems and regulatory compliance. A key component is formulation science, which involves designing dosage forms such as tablets, capsules, injections or topical creams that ensure optimal drug stability, bioavailability and patient compliance. Innovations in drug delivery-like liposomes, nanoparticles and transdermal patches-have significantly enhanced the Pharmaceutical technology focuses on applying scientific and engineering principles to the design, development and manufacturing of safe, effective and high-quality medicines and drug delivery systems. It encompasses a broad range of activities, from preformulation studies and large-scale production of bulk drugs to the creation of diverse dosage forms like tablets and injections. Key aspects include understanding drug properties, optimizing formulations for improved drug efficacy and patient compliance and navigating complex regulatory guidelines to ensure drug safety and quality. Emerging technologies, such as artificial intelligence for drug discovery and bioprinting for novel delivery systems, continue to expand the field's capabilities, driving innovation in drug product design and development for better patient outcomes. Manufacturing technology in this field employs advanced machinery and automation to scale up production while maintaining quality. Techniques like granulation, coating and sterilization are crucial in ensuring product uniformity and safety. The use of Good manufacturing Practices (GMP) ensures that each batch of medication meets strict regulation standards. Quality control and assurance are essential aspects, involving rigorous testing of raw materials, intermediate products and finished pharmaceuticals. Analytical techniques like HPCL (High-Performance Liquid Chromatography) and spectroscopy are widely used.

## DEVELOPMENT AND CHARACTERIZATION OF MAGNETIC GELS FOR CONTROLLED AND TARGETED DRUG DELIVERY

Bhavika Awasthi and Nayana Jain
Department of Pharmaceutical Quality Assurance, Sinhgad College of Pharmacy, Vadgaon (Bk), Pune, Maharashtra, India-411002.
awasthibhavika2@gmail.com

This research documents the development and characterization of magnetic gels (MGs) as a delivery platform for controlled release of drugs. MGs were synthesized by incorporating iron oxide nanoparticles into natural polymers like alginate and chitosan, and synthetic polymers like Pluronic F127 and PNIPAM through cross-linking and in-situ synthesis methods. The gels formed were then systematically evaluated for their mechanical properties, thermal stability, and response to external magnetic fields. Among the prepared formulations, the optimized MGs had greater entrapment efficiency and sustained drug release pattern, along with an enhanced therapeutic response when subjected to magnetic hyperthermia. Microscopic and structure analyses showed a homogeneous dispersion of nanoparticles in the gel matrix, while SEM imaging established a stable morphology suitable for biomedical application. Initial in vitro release studies also showed that these systems are capable of site-specific delivery with satisfactory spatial control. However, some limitations like incomplete nanoparticle clustering and variation in release rates were observed, which suggests room for further optimization. Together, the results indicate that MGs are an exciting nanocomposite system for use in oncology, infectious disease treatment, and wound healing with future promise in personalized 3D-printed hydrogel geometries and multi-function therapeutic devices.

**Keywords:** Magnetic gels, Drug delivery systems, Iron oxide nanoparticles, Controlled release, Nanocomposites.

**PC-92**

## MAGNETIC DUAL-PHASE MAKEUP REMOVER WITH ENZYME MICROCAPSULES: A NOVEL COSMECEUTICAL APPROACH

Shreya Mulay and Sarika Wavhale
Department of Pharmaceutical Quality Assurance, Sinhgad College of Pharmacy, Vadgaon (Bk), Pune, Maharashtra, India-411002
shreyamulay172@gmail.com

Conventional makeup removers rely heavily on surfactants and solvents, which often leave residues and may cause skin dryness or irritation. The present study focuses on the development of a dual-phase magnetic makeup remover incorporating enzyme microcapsules, aiming to achieve efficient, skin-friendly cleansing with added novelty of magnetic action. The aqueous phase was formulated using purified water, glycerine, phosphate buffer (pH 5.5–6.0), trehalose as enzyme stabilizer, and encapsulated enzymes (lipase and protease) prepared via ionotropic gelation using sodium alginate and calcium chloride. The oil phase consisted of isopropyl myristate, tocopherol, polysorbate-80, and cosmetic-grade iron oxide ($Fe_3O_4$, 0.2%) to provide magnetic responsiveness. Both phases were combined into a biphasic system designed to redisperse upon shaking. A magnetic cleansing pad composed of microfiber fabric embedded with a coated neodymium magnet was fabricated to assist in the physical removal process. The formulation was evaluated for physical stability, phase separation, enzyme activity retention, viscosity, and makeup removal efficiency using artificial skin models. Stability testing confirmed intact dual-phase separation with uniform redispersion, while enzyme microcapsules maintained >85% activity after one month. The magnetic pad enhanced removal efficiency by lifting the oil–makeup complex, outperforming a marketed control formulation ($p<0.05$). In conclusion, this novel system integrates enzymatic degradation of cosmetic residues with magnetically assisted removal, offering a safe, effective, and innovative cosmeceutical solution with potential for commercial application.

**Keywords:** Dual-phase remover, enzyme microcapsules, iron oxide, magnetic pad, cosmeceutical innovation.

## BERBERINE LOADED BIGEL: A DUAL-PHASE TOPICAL SYSTEM FOR SKIN REJUVENATION

Sahasrabdi Majhi, Arnab Nandi, Sampriti Bera, Soma Das*
Department of Pharmaceutical Technology, School of Health and Medical Sciences, Adamas University, Kolkata 700126
sahasrabdi.majhi2000@outlook.com

The study addresses the pressing challenge of skin aging by developing advanced topical delivery systems, integrating natural antioxidants with innovative carrier technologies. Berberine hydrochloride, known for its robust antioxidant, anti-inflammatory, and antimicrobial properties, was chosen as the active agent; a biphasic bigel system combining hydrogel (hydrophilic) and organogel (lipophilic) phases was formulated to enhance skin penetration and therapeutic potential. Hydrogel was optimized using central composite design, employing kappa-carrageenan and starch as gelling agents. The organogel phase consisted of sesame oil, jasmine floral wax, and Span 80. Multiple bigel formulations with varying hydrogel-to-oleogel ratios were prepared and characterized for physicochemical properties, including pH, spreadability, viscosity, and drug content. Advanced analytical techniques such as FTIR, TGA, DSC, XRD, and SEM were used for compatibility, thermal stability, crystallinity, and morphology assessment. In vitro drug release was measured via dialysis membrane diffusion, and antioxidant activity was determined using DPPH assay. Stability studies evaluated integrity under room and refrigerated conditions. The optimized bigel displayed desirable pH, spreadability, and viscosity suitable for topical application. Highest drug content and sustained release over 24 hours were observed in hydrogel-rich formulations, with up to 91% drug release. The bigel's antioxidant activity was superior to berberine alone, likely due to synergistic effects from excipients. Thermal and structural analyses confirmed enhanced stability and no incompatibilities. Stability studies demonstrated robust formulation behaviour over three months, with no phase separation or microbial growth. Berberine-infused bigel systems offer a promising hybrid delivery platform for skin rejuvenation, ensuring sustained release, enhanced antioxidant activity, and stable physicochemical properties. The results pave the way for clinical translation and further in vivo investigations of bigel-based phytopharmaceuticals for dermatological applications.

**Keywords:** Berberine Hydrochloride, Bigels, Central Composite Design (CCD), Skin Rejuvenation, Hydrogel Optimization, Hybrid Gel System.

## EVALUATION OF NEUROPROTECTIVE ACTIVITY OF BACOSIDE-LOADED NANOPARTICLES IN SCOPOLAMINE INDUCED ALZHEIMER'S DISEASE IN ZEBRAFISH MODEL (DANIO RERIO)

Bharathi Kalyanam, B. Hari Chandana, B A Vishwanath
Department of Pharmacology, Aditya Bangalore Institute of Pharmacy Education & Research, Yelahanka, Bangalore – 560064, Karnataka, India
kalyanam.bharathi@gmail.com

Alzheimer's disease (AD) is a multifactorial neurodegenerative disorder characterized by progressive cognitive decline, cholinergic dysfunction, oxidative stress, and neuroinflammation. Current pharmacological interventions provide only symptomatic relief without altering disease progression. To overcome these limitations, we explored a novel nanotechnology-based approach employing bacoside-loaded solid lipid nanoparticles (BLNPs) derived from Bacopa monnieri, a traditional nootropic herb. BLNPs were formulated using a pre-emulsion ultrasonication–solvent evaporation technique and extensively characterized by particle size analysis, zeta potential, Fourier-transform infrared spectroscopy (FTIR), and scanning electron microscopy (SEM), confirming nanoscale stability and successful drug loading. A scopolamine-induced zebrafish (Danio rerio) model of Alzheimer's disease was established to evaluate neuroprotective efficacy. Behavioural performance was assessed via T-maze and inhibitory avoidance paradigms, while biochemical assays measured acetylcholinesterase (AChE) activity, lipid peroxidation (MDA), and antioxidant enzymes (SOD, CAT, GPx). BLNP-treated zebrafish exhibited significantly improved memory retention, reduced oxidative stress, and normalized cholinergic function compared to pure bacoside and standard rivastigmine treatment. Histopathological analysis further confirmed neuronal preservation in BLNP-treated groups. Acute toxicity studies demonstrated excellent safety margins, supporting translational potential. Collectively, this study highlights that nano formulated bacosides exert superior neuroprotective effects by synergistically modulating oxidative, cholinergic, and inflammatory pathways. This innovative therapeutic strategy offers a promising platform for developing plant-based, nano-enabled interventions for Alzheimer's disease and related neurodegenerative disorders.

**Keywords:** Alzheimer's disease; Bacopa monnieri; Bacoside-loaded nanoparticles.

## FABRICATION AND EVALUATION OF INNOVATIVE TRANSFEROSOMAL NANOFORMULATION OF PIRFENIDONE FOR ENHANCED GANGRENE TREATMENT

TEENA PARMAR
Sanjeev Agrawal Global Educational (SAGE) University BHOPAL
teenu96@gmail.com

Anti-inflammatory and antifibrotic properties of pirfenidone (PFD) holds promise as a treatment for gangrene. However, its limited solubility and poor absorption restrict its therapeutic potential. To enhance topical delivery and efficacy, a transferosomal nanoformulation of PFD (PFD-TFNs) was developed and evaluated. PFD-TFNs were prepared by the thin-film hydration method and characterized for particle size, polydispersity index (PDI), and zeta potential using dynamic light scattering. Drug loading (DL), encapsulation efficiency (EE), in vitro release, ex vivo skin penetration, antibacterial activity, and in vivo histopathological outcomes were assessed. The optimized PFD-TFNs exhibited a mean particle size of 145.6 ± 6.2 nm, PDI of 0.21 ± 0.03, and zeta potential of −28.4 ± 1.5 mV. DL and EE were 14.5 ± 0.7% and 92.3 ± 2.8%, respectively. In vitro release demonstrated sustained drug liberation (78.6 ± 3.4% after 24 h) compared to a conventional gel (42.7 ± 2.1%). Ex vivo skin permeation studies revealed significantly enhanced flux (12.8 ± 0.9 µg/cm²/h), 2.6-fold higher than the standard gel. Antimicrobial evaluation showed larger inhibition zones for PFD-TFNs against Staphylococcus aureus (19.2 ± 0.8 mm) and Pseudomonas aeruginosa (17.5 ± 0.6 mm) than free PFD (13.6 ± 0.7 mm and 12.4 ± 0.5 mm, respectively). Histopathological examination in a diabetic gangrene rat model demonstrated reduced inflammation and improved tissue regeneration. These findings suggest that PFD-TFNs can overcome solubility limitations, improve skin penetration, enhance antibacterial activity, and provide superior therapeutic outcomes, highlighting their potential as an effective topical strategy for gangrene management.

**Keywords:** Pirfenidone, Transferomal nanoparticles, Gangrene treatment, Topical drug delivery, Antimicrobial activity.

## FORMULATION AND EVALUATION OF MOUTH DISSOLVING FILM OF GLUCOSAMINE SALT OF 5-METHYL TETRAHYDRO FOLIC ACID

Shubh Patel, Durva Vyas*, Dwija Patel, Grishma Patel
K B Institute of Pharmaceutical Education and Research
dsvyas09@gmail.com

This study investigates the formulation and evaluation of mouth-dissolving films (MDFs) containing the glucosamine salt of 5-methyltetrahydrofolic acid (Quatrefolic®) to improve folate bioavailability and patient compliance. MDFs provide an effective and convenient alternative to conventional tablets, especially for individuals with swallowing difficulties. The films were prepared using the solvent casting technique, with hydroxypropyl methylcellulose (HPMC E5 LV) as the main film-forming polymer, polyethylene glycol 400 (PEG 400) as a plasticizer, and sucralose along with peppermint flavor for taste masking and palatability. A design of experiments (DoE) approach was employed to optimize the formulation by studying the effects of polymer and plasticizer concentrations on key parameters such as film weight, thickness, folding endurance, disintegration time, and drug release profile. The optimized formulation produced smooth, non-sticky, flexible films with a disintegration time of 50 seconds and drug release exceeding 85% within five minutes, ensuring rapid onset of action. Drug content uniformity was greater than 95%, indicating reliable dosage delivery. Stability studies conducted over 30 days as per ICH guideline revealed no significant changes in physicochemical properties, confirming the robustness of the formulation. The findings demonstrate that the

ISBN: 978-81-980623-8-3

developed MDFs of glucosamine salt of 5-MTHF are stable, rapidly dissolving, and an effective alternative for folate supplementation. This dosage form is particularly beneficial for individuals requiring quick absorption and enhanced bioavailability.

## COLLAGEN-BASED BIO-COMPOSITE FILM: DEVELOPMENT AND EVALUATION FOR ENHANCED WOUND HEALING

Arnab Nandi, Sahasrabdi Majhi, Uday Shankar Das, Soma Das*
Department of Pharmaceutical Technology, School of Health and Medical Sciences, Adamas University, Kolkata 700126
arnab1.nandi@stu.adamasuniversity.ac.in

An ideal environment is necessary for the complex biological process of wound healing in order to support angiogenesis, tissue regeneration, and cell migration. Because of their biocompatibility, biodegradability, and capacity to replicate extracellular matrix, natural polymers like collagen have drawn interest. Novel bio-composite films that combine collagen with bioactive compounds or polymers were created in order to solve the drawbacks of traditional dressings, and their potential for wound healing was assessed. To create bio-composite films using the solvent casting method, collagen was extracted and combined with appropriate natural or synthetic polymers and plasticizers. The physicochemical characteristics of the films (thickness, tensile strength, folding endurance, swelling index, and water vapor transmission rate) were described. Utilizing FTIR, DSC, and SEM, structural integrity and compatibility were examined. Assays for biocompatibility and drug release were conducted in vitro. Using a rat excision wound model, the effectiveness of wound healing was evaluated by tracking histological alterations, wound contraction, and the duration of epithelialization. The produced collagen bio-composite films have the ideal mechanical strength, consistent thickness, and flexibility to be used as wound dressings. SEM demonstrated a smooth and porous shape that supports cell adherence, whereas FTIR verified polymer–drug interactions. The films had sufficient water vapor permeability and demonstrated regulated hydration and moisture retention. When compared to control, in vivo experiments showed noticeably faster wound contraction, a shorter epithelialization period, and increased collagen deposition. Angiogenesis, re-epithelialization, and well-organized granulation tissue were all verified by histopathological analysis in the treated group. For applications involving wound healing, collagen-based bio-composite films shown advantageous mechanical, biological, and physicochemical characteristics. According to the findings, these films can be a viable substitute for traditional wound dressings since they foster tissue regeneration and offer a moist healing environment. To determine their therapeutic potential, more clinical research is necessary.

## SOLUBILITY AND DISSOLUTION ENHANCEMENT OF ATORVASTATIN CALCIUM BY NANOCRYSTAL TECHNIQUE AND DEVELOPMENT OF FAST DISSOLVING TABLETS

Matterozy and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
Paramajyothi1404@gmail.com

This study focuses on the development of nanocrystal (NC) based fast dissolving tablets (FDTs) of Atorvastatin calcium to enhance its solubility, dissolution, and bioavailability. Atorvastatin calcium, a poorly water-soluble lipid-lowering drug, was successfully processed into nanocrystals using the solvent-antisolvent precipitation method, optimized through a $2^3$ factorial design by varying stabilizer concentration, solvent to antisolvent ratio, and stirring speed. The prepared nanocrystals exhibited significantly higher saturation solubility than the pure drug due to reduced particle size. FDTs containing 20 mg of Atorvastatin calcium nanocrystals were formulated via direct compression using crosscarmellose sodium (CCS) and sodium starch glycolate (SSG) as superdisintegrants. Pre compression and post compression evaluations confirmed excellent flow properties, mechanical stability, and compliance with pharmacopeial standards. Among the six formulations, F3, containing 20 mg of CCS, demonstrated the shortest disintegration time (10.6 seconds) and the highest drug release (95.02% within 12 minutes). These findings highlight the potential of nanocrystal-based FDTs in improving Atorvastatin's bioavailability and addressing limitations associated with conventional tablet formulations, offering a promising alternative for better patient compliance and therapeutic efficacy.

**Keywords:** Nanocrystals, (NC), Fast Dissolving Tablets (FDTs), Solubility, Dissolution, Direct compression and Lipid-lowering drug.

## FORMULATION AND EVALUATION OF NANOEMULGEL (NEG) CONTAINING LIQUORICE EXTRACT FOR DENTAL CARIES

Ramana R, Rashmi P C, Revathi V, Mythilie E, Sagar G R And Dr. Sowjanya Battu
Department Of Pharmaceutics, Aditya Banglore Institute of Pharmacy Education & Research, Yelahanka, Kogilu-560064, Karnataka,India.
ramana98865@gmail.com

A liquorice-based nanoemulgel was developed and thoroughly assessed for enhanced buccal drug delivery, aiming to improve anti-caries activity through stable nano-sized droplets. Using rotor-stator technology and high-speed homogenization, an optimized nanoemulsion was formed by intense shear forces and surfactants, enabling effective encapsulation of Glycyrrhiza glabra (liquorice), a compound known for potent therapeutic and antimicrobial effects. Formulation optimization, performed with Design Expert Software, prioritized minimizing particle size and maximizing entrapment efficiency, resulting in improved drug loading, stability, and buccal mucosal penetration. Comprehensive characterization confirmed the nanoemulgel's ideal particle size, robust encapsulation efficiency, and excellent physical stability. The optimized liquorice nanoemulsion, integrated into a gel base, yielded a formulation that was highly spreadable and remained stable across different temperatures. Physicochemical analyses and in vitro drug release studies demonstrated sustained release kinetics, supporting consistent drug delivery and prolonged therapeutic action. The nanoemulgel exhibited significant antimicrobial activity against cariogenic pathogens, highlighting its strong potential for enhancing oral health and caries prevention. This innovative buccal delivery system offers a patient-friendly, non-invasive approach to the administration of liquorice, with promising antimicrobial and anti-caries efficacy. The results suggest valuable clinical benefits, though further in-vivo and clinical evaluations are necessary to validate safety, efficacy, and commercial feasibility for oral health application.

khandekarpallavi992@gmail.com

The study addresses the increasing public health concern of injuries, which account for millions of deaths and significant morbidity. It explores the intricate structure and vital functions of human skin, emphasizing the role of endogenous electric potential in wound healing. However, study aims to develop and characterize an innovative electroconductive wound healing dressing that integrates silver nanoparticles, lidocaine, chitosan, and polyaniline to enhance healing through electrical stimulation. Using solvent casting, formulation are optimized for effective film formation and characterized for swelling, mechanical property and biodegradation study. Comprehensive analyses include FTIR, DSC, XRD and cytotoxicity assessments, validate effectiveness of dressing and confirm the structural integrity. In vitro study demonstrated

ISBN: 978-81-980623-8-3

most significant cell growth, biocompatibility and angiogenesis in growth factor containing electroconductive Patch. The electroconductive dressing demonstrates broad-spectrum antimicrobial properties, and accelerated healing rates. In vivo study reveals that the electroconductive patch significantly reduces the complete epithelization period to 18 days. The findings suggest that multifunctional electroconductive patch could represent a significant advancement in wound care, addressing limitations of current treatments, promoting faster and more efficient healing processes.

**Keywords:** wound healing, electroconductive , polyaniline, chitosan

**FORMULATION, DEVELOPMENT& INVITRO EVALUATION OF SUSTAINED RELEASE MATRIX TABLETS OF VILDAGLIPTIN**

M.Tejasree & Dr.Kantlam Chamakuri
Department of Pharmaceutics, Brilliant grammar group of institutions, Hyderabad, Telangana,India.
tejasreesista9@gmail.com

The main aim of present work was to formulate and evaluate sustain release matrix tablets of Vildagliptin is an oral anti-hyperglycemic agent (anti-diabetic drug) of the dipeptidyl peptidase-4(DPP-4) inhibitor class of drugs. Sustain release formulation are those which delivers the drug locally or systemically at a predetermined rate for a fixed period of time. The matrix tablet was prepared by direct compression method using by various concentration of Sodium CMC, Acacia and Tragacanth various release retardant polymer. The powder mixtures were subjected to various pre-compression parameters such as angle of repose, bulk density, tapped density and Carr's index shows satisfactory result and the compressed tablets are evaluated for post-compression parameters such as weight variation, thickness, hardness, friability, drug content, in-vitro dissolution studies. In-vitro dissolution studies were carried out for 12 hours using 0.1 NHCL for first 2 hours and pH 6.8 phosphate buffer for 12 hours and the result showed that formulations V3 showed good dissolution profile to control the drug release respectively .Formulation containing higher concentration of Sodium CMC polymer sustained the drug release for the period of 12 hours. The kinetics studies the optimized formulation followed Zero order release kinetics.

**Keywords:** Vildagliptin, Sodium CMC, Acacia, Tragacanth, Direct compression and Sustained release matrix tablets.

**AMYLOIDOGENIC BSA–HYALURONIC ACID NANOHYDROGEL DRESSING FOR ENHANCED DIABETIC WOUND HEALING VIA ANGIOGENESIS AND ANTI-INFLAMMATORY MODULATION**

Girish Kumar Sahu, Parag Jain, and Ajazuddin
Rungta College of Pharmaceutical Science and Research, Bhilai (CG)
sahugirish146@gmail.com

Protein-based nanomaterials have emerged as promising platforms in regenerative medicine owing to their inherent biocompatibility, tunable assembly, and multifunctional therapeutic potential. In this study, we report the development of a self-assembled composite nanohydrogel, fabricated from bovine serum albumin (BSA)-derived amyloid fibrils and hyaluronic acid (HA), designed as a 3D-printed wound dressing for diabetic wound management. The composite hydrogel integrates the bioactive functions of HA with the mechanical robustness of amyloid fibrils, providing a stable and moist wound microenvironment. Physicochemical characterization demonstrated excellent water retention, rheological tunability, and mechanical integrity. In vitro assays revealed superior biocompatibility and fibroblast migration, while in vivo diabetic wound models confirmed accelerated wound closure in the composite (BSA+HA) group compared to single-component controls. Histological analysis highlighted enhanced collagen deposition, reduced inflammation, and pronounced angiogenesis, collectively contributing to improved re-epithelialization. These findings suggest that the BSA–HA composite nanohydrogel dressing represents a translationally relevant strategy for rapid diabetic wound repair through synergistic bioactivity and structural reinforcement.

**Keywords:** Diabetic wound healing, Amyloid fibrils, Hyaluronic acid hydrogel, Anti-inflammatory biomaterials, Protein-based nanomaterials

**DESIGN AND CHARACTERIZATION OF MUCOADHESIVE BUCCAL FILMS FOR SUSTAINED RELEASE OF METFORMIN**

M.Ravindar, M.Ramasamy
Department of pharmaceutical Sciences, Sri Lakshminarayan College of Pharmacy, Dharmapuri, Tamilnadu, India-636809.
ravindarmadesh@gmail.com

The present study focuses on the development and evaluation of mucoadhesive buccal films as an alternative delivery system for Metformin, aiming to enhance its bioavailability and patient compliance while minimizing gastrointestinal side effects. Metformin, a widely used antidiabetic drug, suffers from poor oral bioavailability due to extensive first-pass metabolism and gastrointestinal degradation. Buccal films were prepared using solvent casting technique employing polymers such as HPMC (Hydroxypropyl methylcellulose), PVA (Polyvinyl alcohol), and Carbopol 934P in various ratios. Glycerin and PEG 400 were used as plasticizers. The films were characterized for physicochemical parameters including thickness, weight uniformity, surface pH, tensile strength, folding endurance, drug content uniformity, swelling index, and mucoadhesive strength. In vitro drug release studies were performed using Franz diffusion cells, simulating buccal conditions, and the release kinetics were analyzed using various mathematical models. The optimized formulation showed sustained drug release over 8 hours, strong mucoadhesive properties, and favorable mechanical strength. FTIR and DSC studies confirmed the compatibility between drug and excipients. The results suggest that the formulated mucoadhesive buccal films can serve as a promising platform for sustained delivery of Metformin, bypassing hepatic metabolism and improving therapeutic efficacy. Further in vivo studies are warranted to confirm the clinical potential of the delivery system.

**Keywords:** Metformin, Buccal films, Mucoadhesive, Sustained release, Drug delivery.

**FORMULATION AND OPTIMIZATION OF ABIRATERONE FOLIC ACID CONJUGATION FOR TARGETED DRUG DELIVERY**

Ambika Singh, Mohammad Adnan Raza, and Dr. Ajazuddin
Department of Pharmaceutics, Rungta College of Pharmaceutical Sciences and Research, Bhilai, C.G., India-490023.
ambikasingh5239@gmail.com

Abiraterone (AT) is US-FDA approved, antiandrogen used for metastatic castration-resistant prostate cancer, with half-life of 12 hours, acts by targeting on CYP17 enzyme It is anticipated that targeted drug delivery will lower the dosage of abiraterone due to its poor oral bioavailability, susceptibility to hydrolysis by esterases, and increased dosing frequency in standard formulations. In order to improve the efficacy and bioavailability of drug administration, the current study intends to create and describe PLGA-Coated Abiraterone nanoparticles by functionalizing them with 1-(3-Dimethyl Aminopropyl)-3-Ethylcarbodiimide Hydrochloride (EDC) and folic acid (FA). Since PLGA is an FDA-approved, biodegradable polymer, it aids in the formation of polymeric nanocarriers, which provide prolonged release, for lipophilic drugs like abiraterone. Additionally, this sophisticated formulation results in a form that is patient-compatible. The formulation (PLGA-FA-EDC-AT) nano-drug was investigated and its morphological and structural characteristics were evaluated, using range of sophisticated instruments such as FTIR, UV-vis Spectroscopy, NMR, SEM, DLS, TLC and XRD. Invitro studies such as cytotoxicity studies on the cell line, Sulforhodamine assay (SRB), Folate receptor binding assay along with in-vitro stability studies at different pH level and in presence of enzymes. The research is expected to yield a stable, effective folate-conjugated delivery system with enhanced anticancer activity and reduced systemic exposure.

Respiratory viral infections remain a significant global health concern, frequently manifesting as upper respiratory tract illnesses such as cough and cold. Conventional therapeutic strategies often provide only symptomatic relief, while systemic administration may be associated

ISBN: 978-81-980623-8-3

with delayed onset of action or unwanted side effects. To address these limitations, the present research focused on the development of a novel essential oil–based nasal inhaler designed to deliver a localized antiviral effect directly at the site of infection. Selected essential oils, enriched with bioactive constituents known for their antiviral, antimicrobial, and anti-inflammatory properties, were incorporated along with excipients providing synergistic benefits such as decongestion, cooling sensation, and analgesic effects. Preformulation studies were carried out to establish physicochemical characteristics and compatibility between the selected components. Analytical methods were developed and validated using UV spectroscopy, HPTLC, and GC-MS to ensure accurate standardization and quantification of the formulation. Formulation trials were optimized to achieve stability, acceptable organoleptic properties, and adequate drug loading onto a nasal inhaler matrix. The optimized batch was further evaluated for drug content, antioxidant activity, and stability under ICH guidelines. Results demonstrated that the essential oil–based formulation exhibited favorable stability, reproducibility, and potential for reducing viral load locally in the nasal cavity. This study highlights the potential of essential oil–based nasal delivery systems as an effective, non-invasive, and patient-friendly approach for the management of upper respiratory tract infections. The developed formulation offers a promising alternative to conventional therapies, supporting the integration of natural antivirals into innovative drug delivery systems.

## FUSIDIC ACID NANOSPONGE GEL: A NOVEL APPROACH TO ENCHANCING SKIN BACTERIAL INFECTION TREATMENT

Sunkara Jyothi Sree and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
srij3460@gmail.com

The present study focuses on the development and evaluation of a Fusidic Acid-loaded nanosponge-based gel as an innovative topical formulation for improving the treatment of bacterial skin infections. Nanosponges were prepared using the emulsion solvent diffusion method, with a $2^3$ factorial design incorporating Ethyl Cellulose (EC), Eudragit, and β-Cyclodextrin (βCD). Among the formulations, F4 (high βCD and Eudragit) exhibited the best production yield and solubility enhancement, making it ideal for further gel formulation. Nanosponge-based gels were formulated using Carbopol 934P, HPMC K100, and CMC and evaluated for homogeneity, pH, viscosity, drug content, and in vitro drug release. All formulations were smooth, white, and uniform, with pH values suitable for topical application. HPMC-based gel (F2) demonstrated the most sustained drug release (81.46%), ensuring longer drug retention at the infection site, while CMC-based gel (F3) exhibited the highest drug release (97.28%). The study confirms that nanosponge-based gels enhance solubility, provide controlled and sustained drug release, and improve patient compliance by reducing dosing frequency. These findings suggest that nanosponge-based gels offer a promising approach for topical Fusidic Acid delivery, improving therapeutic efficacy in bacterial skin infections.

**Keywords:** Fusidic Acid, Nanosponge, Emulsion Solvent Diffusion, Topical Gel and Sustained Drug Release.

## A COMPARATIVE ANALYSIS OF DIFFERENT FORMULATIONS OF ANTIHYPERTENSIVE DRUGS: IMPACT ON EFFICACY AND PATIENT COMPLIANCE

Bichitra Sahoo and Jainee Vashi
M. Pharm Research Scholar, Parul Institute of Pharmacy and Research, Parul University, Vadodara, Gujarat,391760
barshab3a@gmail.com

Hypertension is one of the common chronic ailments where there is a continual rise in blood pressure (systolic ≥130mmHg and diastolic ≥80mmHg). In India, it is reported to affect adults aged over 30 years, with a prevalence of 30 %among men and 29 % among women with a higher prevalence of urban men (34 %) than rural men (29 %). Hypertension is one of the main causes of the cardiovascular morbidity and mortality worldwide, and its control is essential. The treatment success is dependent on not only antihypertensive agents efficacy but also on the patient adherence. A dual study was organized, the first study was patient based and conducted with one structured google form questionnaire, and the second study was based on the expert point of view and was carried out via another structured google form questionnaire for healthcare professionals. The study protocol was reviewed and approved by Ethics board of Satyam hospital, Vadodara. A total of 200 patient responses were analysed for efficacy of different formulations, each having 40 responses, among which oral tablets showed the highest efficacy ratings (97.5%) while transdermal patches have lowest i.e. 10%. Likewise for patient compliance a total of 240 responses recorded over six different categories, from which reminder system got highest compliance (92.5%).This study shows comparative analysis of various antihypertensive formulations highlighting their effect on efficacy and patient compliance. The outcomes emphasize the value of individualized formula selection to optimize hypertension management.

## DEVELOPMENT AND OPTIMIZATION OF VENETOCLAX-LOADED NANOMICELLES USING QBD FOR IMPROVED BIOAVAILABILITY

Ravikiran R Kanabargi1*, Archana S Patil1
1Department of Pharmaceutics, KLE College of Pharmacy, Belagavi, KLE Academy of Higher Education and Research, Belagavi, Karnataka, India 590010
ravikirankanabargi@klepharm.edu

Venetoclax, a selective BCL-2 inhibitor, is approved for chronic lymphocytic leukemia (CLL) and acute myeloid leukemia (AML). However, its low aqueous solubility and poor oral bioavailability (5.4% in fasting state) restrict clinical utility, leading to high dose requirements and adverse effects. To address these limitations, a nanomicelle-based drug delivery system was developed using a Quality by Design (QbD) approach . Nanomicelles were prepared by solvent evaporation–thin film hydration employing Pluronic F127 and surfactants (Tween, Labrafac PG), and optimized by Box-Behnken design. The optimized formulation exhibited particle size 176 nm, zeta potential –13 mV, PDI 0.25, entrapment efficiency of 84.77% and the drug release was foud to be 91.50 % at 24th hour. SEM confirmed spherical, uniform micelles with smooth morphology. To enable patient-friendly administration, nanomicelles were incorporated into oral films using HPMC E5 as polymer and propylene glycol as plasticizer. The films showed satisfactory thickness (0.41mm), folding endurance (86 folds), surface pH of 6.9, and rapid disintegration (59 seconds). Overall, the nanomicelle-based formulation demonstrated improved solubility and stability, while sublingual delivery offers the potential for enhanced bioavailability, reduced dose burden, and improved patient compliance. This strategy highlights a promising platform to overcome solubility and bioavailability issues associated with Venetoclax therapy.

## FORMULATION OF SILVER NANOPARTICLES LOADED WITH DIACEREIN BY USING NANOPRECIPITATION METHOD

Parameshwari.R, Nanthakumar.A.
Department of Pharmaceutical Chemistry and Analysis, Dr. Kalam college of pharmacy, Avanam, Thanjavur (Dt)-614623.
reachshanmuganathan@gmail.com

Green silver nanoparticles (AgNPs) have emerged as promising drug carriers due to their distinct physical, chemical, and biological properties. In this study, AgNPs were synthesized by green methods using Aloe vera leaf extract with 1 mM aqueous silver nitrate solution, where the formation of a dark brown color confirmed nanoparticle generation. To address the poor solubility of diacerein, the drug was incorporated into these nanoparticles through the nanoprecipitation method. Samples were prepared under three different conditions, stored under refrigeration, and concentrated using a rotary vacuum evaporator. Characterization was carried out using scanning electron microscopy (SEM), zeta sizer, and particle distribution (PD) analysis. Among the three

ISBN: 978-81-980623-8-3

formulations, Sample B demonstrated superior stability, uniformity, and optimal nanosuspension quality compared to Samples A and C. The nanoscale reduction in particle size increased surface area and wettability, ultimately enhancing diacerein's solubility and potential bioavailability. Characterization through dynamic light scattering (DLS), zeta potential, and SEM confirmed stability and uniform morphology. Moreover, the study underscores the significance of plant-mediated green synthesis, where extracts act as both reducing and stabilizing agents, minimizing the use of toxic chemicals. These AgNPs not only enhanced dissolution but also possess inherent antimicrobial properties, offering dual therapeutic benefits. The findings highlight silver nanoparticles as an efficient carrier for poorly soluble drugs, paving the way for more effective drug delivery strategies and improved therapeutic outcomes.

Onychomycosis is a fungal nail infection causing brittleness. We aimed to develop a topical nanoemulgel system of selective allylamine BCS class IV agent, Naftifine HCl, to increase drug release and permeation to deeper nail layers. Nanoemulgel was prepared by titrating different ratios of oil (neem) to Smix ratios (tween 80+ propylene glycol) (1:1, 1:2, 1:3, 2:1, and 3:1), with an aqueous phase. The nanoemulsion zone was identified using a pseudo-ternary phase diagram. Formulations were prepared after selecting ten ports in the nano emulsion region, and evaluated for clarity and particle size. The selected nanoemulsion formulation was converted to nanoemulgel by incorporating it into a carbopol 934 gel base. The nanoemulgel was evaluated for pH, drug content, and viscosity. The in vitro and ex vivo drug release profiles of nano emulgel and pure drug was compared. The oil: Smix ratio affected the droplet size and zeta potential of nanoemulsions. Results of in vitro and ex vivo release studies showed good correlation between drug release and permeation via sheep hooves. A considerable increase in drug permeation occurred with the penetration enhancer thiourea. Thus, nanoemulgel is a promising, economical approach to treat deep fungal nail infections.

**DEVELOPMENT OF APTAMER-FUNCTIONALIZED FLAVONOIDS NANOLIPOSOMES: EVALUATION AGAINST METASTATIC MELANOMA.**

Uday S Huded and Dr. Moumita Dhara
Department of Pharmacology, Nitte college of pharmaceutical sciences, Yelahanka, Bengaluru -560064
Udaykumarsh01@gmail.com

Metastatic melanoma is an ongoing global health challenge and is the second leading cause of cancer-related death globally. Metastatic melanoma is lethal due to its aggressive nature, rapid invasion and poor prognosis. Current immune therapeutic approaches have not been successful enough to overcome drawbacks including chemoresistance, recurrence after radiation, and systemic toxicity. While flavonoids like apigenin and quercetin have shown medicinal potential against key melanoma targets (BRAF and MEK), their clinical use is often limited by low bioavailability and stability. To overcome these issues, we propose apigenin-loaded nanoliposomes with aptamer functionalization having particle size approx 150-180nm range with zeta potential (-20 mV). Further we confirmed conjugation and surface morphology by FESEM and Cryo TEM. Aptamers are chemically synthesized oligonucleotides that have high specificity and affinity for melanoma cells. We observed significant incremental cytotoxicity for aptamer optimized nanoliposomes in melanoma cell lines in comparison to non-aptamer functionalized formulation. The aim is to develop the nanoliposomes, modify them to create melanoma specific uptake, leading by their molecular mechanism. We will carry out in vitro studies in melanoma cell lines to assess cellular uptake, apoptosis and gene expression related to their cell signaling and observed more than five times superior effectivity in comparison to the non-aptamer conjugated flavonoid nanoliposomes. Further, in vivo studies will utilize a C57BL/6 murine melanoma model to assess biodistribution, efficacy, and safety. Overall, the aptamer-guided nanocarrier system is expected to provide better selectivity and therapy than other options and provide a novel, nanomedicine-based approach to treating metastatic melanoma.

**DEVELOPMENT AND EVALUATION OF LENVATINIB LOADED EMULGEL FOR SKIN CANCER TREATMENT**

Kumari lata1,2, Anjila Firdous1,2, Mohammad Adnan Raza1,2, Ajazuddin1,2
Rungta College of Pharmaceutical Science and Research Bhilai, Chhattisgarh, INDIA-40023
Development of Pharmacy, Rungta International Skill University, Kohka Kurud Road, Bhilai, INDIA-490023
latakurrey379@gamil.com

The present research, titled "Development and Evaluation of Lenvatinib Loaded Emulgel for Skin Cancer Treatment," focuses on the formulation of a topical drug delivery system utilizing Lenvatinib, a multi-targeted tyrosine kinase inhibitor, for effective and localized management of skin cancer. Conventional systemic therapies often suffer from severe side effects and poor patient adherence, underscoring the need for site-specific, non-invasive alternatives. To address this, an Emulgel a hybrid formulation combining the benefits of emulsions and gels was developed to enhance the solubility, stability, and dermal penetration of Lenvatinib. Preformulation studies included solubility screening, FTIR analysis for compatibility, and UV spectroscopy to determine λmax (248 nm). Emulgels were prepared using Carbopol 940 as a gelling agent, Tween 80 and Span 80 as emulsifiers, and oleic acid and propylene glycol as permeation enhancers. Several batches with varying drug and excipient ratios were evaluated for key physicochemical parameters such as pH, spreadability, viscosity, homogeneity, stability, and drug release. Among the tested formulations, the medium concentration batch (F1) demonstrated optimal performance, with a pH near the skin's physiological range, good spreadability, and sustained drug release. No chemical incompatibilities were observed. Microbial testing confirmed the formulation's safety for dermal use. The study concludes that Lenvatinib-loaded emulgel offers a promising alternative to systemic chemotherapy for localized skin cancer treatment. It ensures site-

ISBN: 978-81-980623-8-3

specific action, prolonged release, reduced systemic toxicity, and improved patient compliance. Future in vivo and clinical evaluations are warranted to validate its therapeutic potential and explore enhancements using natural excipients or synergistic drug combinations.

**QUALITY BY DESIGN BASED DEVELOPMENT OF EXTENDED-RELEASE BILAYER TABLETS OF METFORMIN AND TENELIGLIPTIN: INVESTIGATING IONIC AND NON-IONIC POLYMER INTERACTIONS**

Anushriya Talukdar and Bipul Nath
Royal School of Pharmacy, The Assam Royal Global University, Guwahati- 781035
anushriyatalukdar01@gmail.com

Quality by Design (QbD) provides a systematic framework for formulation optimization. This study aimed to develop extended-release bilayer tablets of Metformin (BCS Class III) and Teneligliptin (BCS Class I) by exploiting ionic and non-ionic polymer interactions to enhance therapeutic efficacy and patient compliance. A QbD approach was employed, beginning with the Quality Target Product Profile (QTPP) and identification of Critical Quality Attributes (CQAs). Risk assessment tools, including Ishikawa diagram and Failure Mode Effect Analysis (FMEA), guided the selection of Critical Material Attributes (CMAs) and Critical Process Parameters (CPPs). Design of Experiments (DoE) was applied to optimize polymer ratios and process variables, focusing on Carbopol (ionic) and HPMC/PEO (non-ionic) in modulating drug release and maintaining bilayer stability. Optimized formulations were evaluated for pre- and post-compression parameters, in-vitro release bilayer integrity, release kinetics, and stability under ICH-recommended conditions. The optimized bilayer tablets exhibited zero-order release kinetics for Metformin with minimal burst effect, while Teneligliptin release was effectively modulated. This work demonstrates a QbD-driven, polymer interaction-based strategy as a robust and reproducible approach for developing extended-release bilayer tablets in fixed-dose antidiabetic therapy.

**BARNYARD MILLET'S STARCH BASED MATRIX TABLET FROM A NEWLY SYNTHESIZED 6, 7-DIMETHOXY-N-ARYL-4-AMINO QUINAZOLINE DERIVATIVE (SERB-111) WITH ANTI-PROLIFERATIVE ACTIVITY AGAINST COLORECTAL CANCER**

Raghav Dixit, Vipin Kumar, Preeti Kothiyal
School of Pharmaceutical Sciences, Swami Rama Himalayan University, Jolly Grant, Dehradun, Uttarakhand 248016
raghavdixitphd1985@gmail.com

This research aimed to synthesized SERB-111 from methyl 3,4-dimethoxybenzoate, with anti-colorectal cancer activity by loading on starch matrix tablet (RTAB-01-S). SERB-111 was synthesized; a UV spectroscopy method was developed and validated to measure RTAB-01-S concentration at various dosage forms (R1-R9) in starch and excipients combinations. SERB-111 loaded with starch (Barnyard Millets) based matrix tablet (RTAB-01-S) were prepared, characterized by Scanning Electron Microscopy (SEM), Fourier Transform Infrared Spectroscopy (FT-IR), Differential Scanning Calorimetry (DSC), X-ray powder diffraction (XRD), in-vitro release, sulforhodamine B (SRB) assay. In-vitro cytotoxicity screening is the sulforhodamine B (SRB) assay of SERB-111 was fed to HCT116 cells at various dosages, a dose-dependent reduction in cell viability was seen. The sample's IC50 value was determined to be 7.95µg/mL. The entrapment efficiency was 97% ± 0.45%, and the in-vitro release showed that the RTAB-01-S enhanced the solubility of the SERB-111. The kinetics and mechanism of drug release for SERB-111 based matrix tablets were ascertained by fitting the data to various models. The best model was chosen using the regression coefficient (R2) as a criterion. Since the regression coefficients (R2) for each of the formulations coated with RDJS-P were within the range of 0.9776 to 0.9946, they were all consistent with the Korsmeyer-Peppas model. In conclusion, the proposed method presents a novel strategy for synthesis of a new SERB-111 derivative based novel drug theraphy for treatment of colorectal cancer.

**FORMULATION AND EVALUATION OF GASTRO RETENTIVE IN SITU GEL OF CIPROFLOXACIN**

Yarramsettti Kalyani and Sadhu Venkateswara Rao
Department of Pharmaceutics,
Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
yarramsetttikalyani2005@gmail.com

The objective of this study was to formulate and evaluate a gastro retentive in situ gel of ciprofloxacin for improved drug delivery. The in situ gel was formulated using a combination of natural and synthetic polymers, and effects of different concentration of sodium alginate, HPMC K-100 and calcium carbonate on viscosity and drug release at 8 hrs were studied. The in situ gel had desirable physicochemical properties and a prolonged drug release profile. All the formulations showed an optimum viscosity that will allow ease of administration and swallowing. Floating lag time of all formulations was between 43- 75 seconds and floated for>12 h. The in vitro gelling capacity increased with increasing concentration of the sodium alginate and calcium carbonate. The formulation F6 showed high swelling index, which indicates that gel is capable of absorbing a large amount of fluid. In vitro drug release form these insitu gels were slow, extended and dependent on the concentration of sodium alginate and HPMC K-100 used. The formulation F6 containing 1.25% sodium alginate and 2% HPMC K-100 showed sustained in vitro drug release (67.23 %) over an extended period of 12 h. Drug release from the formulation F6 followed first order kinetics. Overall, the study demonstrated the potential of in situ gel-based drug delivery systems for improving the performance of ciprofloxacin.

**Keywords:** Gastro retentive, In situ gel, Floating time, In-vitro drug release and Ciprofloxacin

**PC-117**

**FORMULATION DEVELOPMENT AND EVALUATION OF LIQUISOLID TABLETS TO IMPROVE THE DISSOLUTION RATE OF TELMISARTAN**

Pothina Yasaswini Devi and Sadhu Venkateswara Rao, Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
yeshusaijyothi@gmail.com

The objective of the present investigation was to improve dissolution and bioavailability of a practically insoluble antihypertensive drug Telmisartan using liquisolid technique. Telmisartan liquisoild compacts was prepared using tween-40 as a nonvolatile solvent, microcrystalline cellulose, lactose, dicalcium phosphate as carrier material and colloidal silica as a coating material in different ratio. The prepared liquisolid compacts were evaluated for the precompression properties like tapped density, bulk density, angle of repose, Carr's compressibility index and Hausner's ratio. The formulated liquisolid compacts were mixed with sodium starch glycolate, magnesium stearate, talc and compressed in to tablets (F1 –F6). Tablets were evaluated for various post compression parameters such as hardness, friability, weight variation, content uniformity, disintegration time, wetting time and in vitro drug dissolution study. The interaction between drug and excipients was characterized by FT-IR studies, which showed that there is no interaction between drug and excipients. The results of pre and post compression parameters were comply with pharmacopoeial limits. In vitro drug dissolution study was carried by using USP dissolution apparatus II & pH 6.8 phosphate buffer for 45 minutes; its results comply with IP limits for tablets. The dissolution study of an optimized formulation (F-4) compared with marketed tablets and it was found that F-4 showed significant higher drug release rate than marketed tablet. From this study, it was concluded that the liquisolid technique is an effective approach to enhance the dissolution rate of Telmisartan.

**Keywords:** Telmisartan, Liquisolid technique, Carrier material, Coating materials and In vitro drug dissolution.

**NANO ENGINEERED RAMIPRIL LIPID CARRIERS FOR ANTIHYPERTENSIVE THERAPY**

Amirdhavarshini.S* and Mrs.Revathi

ISBN: 978-81-980623-8-3

Department of pharmaceutical sciences, The Tamilnadu Dr.MGR University, Chennai – 32
amirdhavarshinisuresh@gmail.com

Ramipril is a widely used angiotensin-converting enzyme (ACE) inhibitor for the management of hypertension; however, its therapeutic effectiveness is limited by poor aqueous solubility, low oral bioavailability, and extensive first-pass metabolism. The present study aimed to develop and evaluate Nano engineered lipid carriers (NLCs) of Ramipril to overcome these limitations and achieve improved antihypertensive efficacy. Ramipril-loaded NLCs were prepared by high shear homogenization followed by ultra-sonication using solid and liquid lipids in combination with surfactants. The prepared formulations were optimized based on particle size, zeta potential, polydispersity index, entrapment efficiency, and drug loading. The optimized NLCs exhibited a mean particle size of less than 200 nm, zeta potential above –25 mV, entrapment efficiency exceeding 80%, and sustained drug release over 24 h. Differential scanning calorimetry and Fourier transform infrared spectroscopy confirmed drug–lipid compatibility, while transmission electron microscopy revealed spherical, uniformly distributed nanoparticles. In-vitro release studies demonstrated biphasic drug release with an initial burst followed by sustained release, whereas in-vivo evaluation in animal models indicated enhanced bioavailability and significant reduction in systolic blood pressure compared to pure drug suspension. The results suggest that Nano engineered Ramipril lipid carriers provide a promising delivery system to enhance oral bioavailability and therapeutic performance in hypertension management.

**Keywords:** Ramipril, lipid nanoparticles, Nano formulation, antihypertensive therapy, pharmaceutical technology.

## ROSMARINIC ACID AS AN ESTROGEN RECEPTOR ALPHA-TARGETED BREAST CANCER THERAPEUTIC: VIRTUAL SCREENING, ORAL LIPID NANOCARRIER FORMULATION, AND IN VITRO EVALUATION

Vaishali Bambal 1, Vijeth Nagesh Bhat2 and Vanaja K1
1 College of Pharmaceutical Sciences, Dayananda Sagar University, Bengaluru, Karnataka, India
2 National Institute of Pharmaceutical Education and Research, Hajipur, India.
vaishalibmbl@gmail.com

Breast cancer (BC) remains a major global health concern among women, with current treatments often relying on hormone receptor modulators like partial agonists and antagonists, which could lead to drug resistance and adverse effects. In this context, in silico strategies provide a valuable alternative by enabling the virtual screening of phytochemicals for potential therapeutic use. This study investigated 238 cancer-preventive phytochemicals for their interaction with Estrogen Receptor alpha, a key target in hormone-responsive breast cancer. Molecular docking was initially performed using AutoDock to evaluate the binding affinity of phytopharmaceuticals with the target protein. The docked compounds were then assessed for drug-likeness and toxicity profiles using SwissADME, Molinspiration, and OSIRIS Data Warrior. Subsequently, protein–ligand interactions were visualized and analyzed with Biovia Discovery Studio to select compounds demonstrating favourable interactions and drug-like properties. Rosmarinic acid (RA) emerged as a promising candidate, showing favorable interaction with ER-α and a low toxicity profile. MM-GBSA binding energy calculations demonstrated that Tamoxifen exhibited a markedly stronger binding affinity to ER-α. To validate binding stability, 200ns molecular dynamics (MD) simulations were performed. Despite slightly higher flexibility, RA maintained stable interactions through multiple hydrogen bonds. For in vitro assessment, RA was encapsulated into oral lipid nanocarrier using the thin-film hydration method. The optimized formulation (OLN-RA) demonstrated stability, uniform particle distribution. In-vitro cytotoxicity assays confirmed an $IC_{50}$ value of 190.9 µg/mL for RA, while the RA-loaded oral lipid nanocarrier exhibited approximately 42% cytotoxicity on MCF7 cell lines. These findings position RA as a stable, natural candidate for further development in breast cancer therapy.

## ISOLATION AND FORMULATION OF WHEAT STARCH FILM

Gaurav Wadhankar, D. L. Bawankar and S. W. Lohe
Department of Pharmaceutics, Anurag College of Pharmacy, Bhandara, Maharashtra, India-441905
gauravwadhankar2002@gmail.com

Natural polymers, such as starch, have attracted the interest of many research groups due to the increasing demand for biodegradable and biocompatible materials in new drug delivery systems (NDDS). Enzymatic or non-enzymatic degradation of such biodegradable polymers in vivo results in biocompatible and non-toxic byproducts. These polymers have been reported to improve drug pharmacokinetics and reduce side effects. Wheat is the common name for Triticum aestivum, a type of grass plant that is part of the Poaceae family. The objective of this research is to isolate and prepare wheat starch in film form for potential use in NDDS, which are environment friendly and economical, featuring a controlled-release drug delivery mechanism. Wheat starch is then isolated from the grain by wet milling and subsequently defatted to remove proteins, lipids, and other impurities. Further, by adding plasticisers (glycerol and sorbitol) to increase flexibility and cross-linking agents (citric acid and glutaraldehyde) to increase mechanical strength, the separated bounce is dried and reused as a film-forming resin with water as a solvent. Physical properties such as moisture content, ash value, pH, bulk density, and tapped density. Also, find out the tensile strength, swelling index, and thickness of the starch film. The results show that the wheat bounce films are a great way to find NDDS as they possess a high film-forming capacity and are biocompatible.

**Keywords:** Triticum aestivum, Extraction, Film Formulation, Solvent casting, Bounce.

## FORMULATION AND EVALUATION OF TRANSETHOSOMAL GEL: FOR TRANSDERMAL DELIVERY OF DIACEREIN

Hemanth SN
Department of Pharmaceutics, SJM College of Pharmacy, Chitradurga, Karnataka, India-577502
hemanthraj1833@gmail.com

The purpose of the work was to formulate and characterize Diacerein loaded Transethosomes. Transethosomes were formulated by using lecithin soya, cholesterol and ethanol by hot method. The prepared Transethosomes were subjected to characterization for morphology, particle size, entrapment efficiency (EE) and in-vitro diffusion behaviour. The results revealed that the vesicles were spherical with a smooth surface, with particle sizes ranging from 1.2 µm to 3.5 µm, and entrapment efficiency between 79.4% and 90.3%. The formulations exhibited a sustained drug release profile for up to 24 hours. Among the different batches, formulation DTE7 demonstrated superior performance based on particle size, entrapment efficiency and drug diffusion studies. Therefore, DTE7 was incorporated into a gel base using carbopol-940 as the gelling agent. The Transethosomal gel was then assessed for physical appearance, homogeneity, pH, spreadability, extrudability, viscosity, in-vitro diffusion, skin irritation, anti-inflammatory potential and short-term stability. The optimized gel (DTEG) appeared pale yellow with smooth texture, good spreadability, satisfactory extrudability, appropriate viscosity and pH and was found to be free from skin irritation. It also showed enhanced drug release, which best fitted the Peppas kinetic model, indicating a non-Fickian release mechanism. In vivo anti- inflammatory studies confirmed that the gel produced a dose-dependent reduction in carrageenan-induced paw edema. Furthermore, the formulation remained stable during short-term stability testing. In conclusion, the developed Diacerein-loaded Transethosomal gel presents a promising alternative to conventional oral therapy, overcoming the limitations associated with oral administration.

**Keywords:** Diacerein, Transethosomes, Transdermal Drug Delivery, Anti-inflammatory Activity.

## CO-CRYSTAL MEDIATED ENHANCEMENT OF RANOLAZINE BIOAVAILABILITY AND SOLUBILITY: IN VITRO AND IN VIVO PHARMACOKINETIC ASSESSMENT IN RATS

Ketkee Mandawar, Kalyani Thombre, Krishna Gupta, Milind Umekar.

ISBN: 978-81-980623-8-3

Department of Pharmaceutical Chemistry, Smt. Kishoritai Bhoyar College of Pharmacy, New Kamptee, Nagpur, Maharashtra, India-441002

The primary focus of this research to enhance the aqueous solubility and oral bioavailability of Ranolazine, an anti-anginal drug with poor water solubility, by formulating pharmaceutical co-crystals using co-formers. In-silico molecular screening was applied to predict compatible co-formers based on intermolecular interactions and stability. From this approach, 2-amino caffeine, nicotinamide, and benzamide were selected for experimental co-crystal development. A series of co-crystals (C1, C2, C3, B1, B2, N1, N2, N3) were synthesized employing solvent drop grinding, antisolvent addition, and slow evaporation techniques. Structural confirmation and physicochemical characterization were performed using UV spectroscopy, FTIR, and DSC analyses. In vitro dissolution studies revealed markedly enhanced release profiles compared to pure Ranolazine. Notably, C1, B2, and N1 co-crystals achieved 100% release within 15, 15, and 25 minutes, respectively. Pharmacokinetic investigations in rats were conducted using a validated RP-HPLC method with hydrochlorothiazide as an internal standard. All co-crystals exhibited maximum plasma concentration at 4 h, while N1 and C1 demonstrated significantly higher Cmax values relative to the pure drug at Tmax, indicating improved systemic availability. The RP-HPLC method was precise, sensitive, and compliant with ICH guidelines. This study highlights the utility of in silico screening in rational co-former selection and confirms the potential of co-crystallization to address solubility and bioavailability challenges associated with Ranolazine. The findings advise that Ranolazine co-crystals could lead to more effective anti-anginal therapy with improved therapeutic performance, laying the groundwork for further preclinical and clinical development.

**Keywords:** Ranolazine, Co-crystals, Pharmacokinetic assessment, Molecular Docking.

## FORMULATION AND IN-VITRO EVALUATION OF ORALLY DISINTEGRATING TABLETS CONTAINING RACECADOTRIL UTILIZING DESIGN EXPERT SOFTWARE

Harshini Vemparala and Haarika Balusu
Department of Pharmaceutics, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Tarnaka, Secunderabad, Telangana-500017, India
vemparalaharshini2002@gmail.com

Racecadotril is a prodrug that is converted into its active metabolite, thiorphan, a selective enkephalinase inhibitor that blocks the enzyme's active site. This inhibition prevents the breakdown of enkephalins, thereby reducing intestinal secretions and treating diarrhea. The tablets were formulated to disintegrate rapidly in the oral cavity, allowing quick drug dispersion and absorption. Orally disintegrating tablets (ODTs) of formulations F1 to F11 were prepared using the sublimation technique. Initial trials employed Avidone as the superdisintegrant and camphor as the sublimating agent. Optimization of these formulations (F1 to F11) was carried out by varying the concentrations of the superdisintegrant and sublimating agent (Avidone at 0.5%, 2.75%, and 5%, and camphor at 5%, 10%, and 15%) to improve disintegration time, friability, and percentage of drug release. Design Expert 13 software facilitated optimization via Central Composite Design from Response Surface Methodology, with ANOVA revealing the influence of independent variables on dependent variables. Preliminary findings indicated that formulations containing both Ac Di Sol and menthol exhibited rapid disintegration and increased drug release. The optimized formulation, labelled as F6, contained 5% Avidone and 15% camphor, achieving a disintegration time of just 4 seconds, a friability of 0.63%, and 99.31% drug release. Characterization studies using FTIR, DSC, and PXRD confirmed the absence of significant interactions between the drug and excipients. Stability studies on the optimized formulations, based on disintegration and dissolution findings, demonstrated good stability

## FORMULATION AND EVALUATION OF METHOTREXATE LOADED CAPPED FLEXOSOMAL GEL

Srilakshmi K T*, Ganesh nayak, A R Shabaraya
Department of Pharmaceutics, Srinivas College of Pharmacy, Mangalore -574143, Karnataka, India.
srilakshmikt0910@gmail.com

Methotrexate, a widely used disease modifying antirheumatic drug (DMARD), is commonly prescribed for the management of rheumatoid arthritis. Topical delivery of methotrexate faces challenges such as poor solubility, limited skin permeation, and instability. The present study aimed to develop a methotrexate-loaded capped flexosomal gel to enhance drug stability, improve dermal penetration, and provide controlled release. Capped flexosomes were prepared using the thin film hydration method and incorporated into a Carbopol gel base to achieve suitable consistency for topical application. The developed formulation exhibited a particle size of 278nm and zeta potential -38.7mV, indicating good colloidal stability. Entrapment efficiency was 88.01% and drug content was 94.44%, demonstrating effective drug loading. In vitro release studies revealed sustained release of 96.91% in 8 hr, suggesting the potential for prolonged therapeutic action. The capping of flexosomes contributed to enhanced vesicle stability and protection of the drug from degradation, while the flexible vesicular structure is expected to facilitate penetration through the stratum corneum. Overall, the methotrexate-loaded capped flexosomal gel demonstrated desirable physicochemical characteristics, making it a promising carrier system for topical management of rheumatoid arthritis. Further in vivo studies are warranted to evaluate the formulations therapeutic efficiency and confirm enhanced bioavailability.

**Keywords:** Methotrexate, capped flexosomes, rheumatoid arthritis, topical gel

## FORMULATION AND EVALUATION OF CLARITHROMYCIN-LOADED SPANLASTIC GEL: A FACTORIAL STUDY

Shalini B, Snehalatha, Maruthi. N
Department of Pharmaceutics, SJM College of Pharmacy, Chitradurga - 577502, Karnataka, India.
raj171574@gmail.com

In the current research Spanlastic gel of Clarithromycin was formulated. The objective was to utilize the advantages of Spanlastics in prolonging drug residence time and improving site-specific action. Spanlastics were prepared by the thin film hydration method and optimized using a 23 factorial design with twelve different formulations containing varying concentrations of Span 60, Span 80, and Tween 80. The optimized formulation exhibited a Particle size of 237.1 nm, a Polydispersity index (PDI) of 0.258 and a Zeta potential of -29.3 mV. Drug Entrapment efficiency and Total drug content were 78.05 and 98.9%, respectively. Compatibility studies using FTIR and DSC confirmed no significant interactions between the drug and the excipients. SEM analysis revealed uniform particle morphology. In-vitro diffusion studies using a Franz diffusion cell demonstrated controlled release from optimized formulation exhibiting 86.2% drug release over 24 hours, which was significantly more sustained compared to the pure drug and Marketed Gel exhibits faster drug release, 98.6% for 8 hours. Additionally, the antibacterial activity of the Clarithromycin Spanlastic gel was evaluated against Staphylococcus aureus and Pseudomonas aeruginosa using the agar well diffusion method. The gel formulation exhibited superior antibacterial activity with larger zones of inhibition, confirming its potential in enhancing the drug's efficacy. These results suggest that optimised Clarithromycin Spanlastic gel formulation is a promising candidate for future clinical applications in treating bacterial infections.

**Keywords:** Clarithromycin, Spanlastic, Factorial Design, Antibacterial Activity

## FORMULATION AND EVALUATION OF NASAL IN SITU GELLING SYSTEM OF ATAZANAVIR

Kiruthika G*, Bhama S, Perumal P
Department of Pharmaceutics, JKK Munirajah Institute of Health Sciences College of Pharmacy, T.N.Palayam, Gobi, Erode
kiruthiganesan2020@gmail.com

Human Immunodeficiency Virus (HIV) continues to be a major health concern worldwide, with the central nervous system (CNS) acting as an important viral reservoir due to the restricted permeability of the blood–

ISBN: 978-81-980623-8-3

brain barrier (BBB). Atazanavir, a potent HIV-1 protease inhibitor, demonstrates poor CNS penetration when administered orally, limiting its efficacy in managing Neuro AIDS. Intranasal drug delivery using in situ gelling systems provides a non-invasive approach to bypass the BBB and achieve direct nose-to-brain targeting. The present study aimed to formulate and evaluate a temperature-triggered nasal in situ gelling system of Atazanavir to enhance brain bioavailability and patient compliance. Pre formulation studies included solubility assessment, melting point determination, and drug–excipient compatibility analysis using FTIR spectroscopy. In situ gels were prepared using temperature-sensitive polymers at varying drug–polymer ratios. The formulations were evaluated for physical appearance, clarity, pH, drug content uniformity, gelation capacity, gelation time, gelation temperature, viscosity and flow properties, sterility, osmotic compatibility, and in vitro drug release behaviour. The optimized formulation (F5, containing Pluronic F127 and HPMC E50LV) showed excellent clarity and transparency, with a pH range of 6.33–6.47, which is compatible with nasal mucosa. Gelation occurred rapidly at physiological conditions with a gelation time of 58 s and gelation temperature of 35 °C.Viscosity was found to be 90–500 cP before gelation and increased significantly to 240–12,000 cP after gelation, confirming a sol–gel transition and pseudoplastic flow behaviour. The drug content was 95.85 ± 0.40%, indicating uniform distribution. In-vitro drug release showed a sustained profile with 92.3% release over 12 hours, following diffusion-controlled kinetics. Isotonicity testing confirmed no effect on blood cell morphology, and sterility studies revealed the formulation was free from microbial contamination. Stability studies indicated no significant changes in clarity, pH, viscosity, or drug contentduring storage. The developed temperature-sensitive nasal in situ gelling system of Atazanavir proved to be a promising strategy for enhancing brain delivery of the drug. This novel formulation offers a patient-friendly, non-invasive, and effective approach for the management of Neuro AIDS by bypassing the BBB and improving therapeutic outcomes.

**BIOTECHNOLOGICAL ENHANCEMENT OF SERINE PROTEASE BIOSYNTHESIS IN BACILLUS PUMILUS THROUGH CULTURE OPTIMIZATION TECHNIQUES**

A Praveen and Mohammed musraf A
Dept of pharmaceutical biotechnology, The erode college of pharmacy,638112
The tamil nadu Dr. MGR university Chennai.
apraveenvjm2005@gmail.com

This research focused on the biotechnological enhancement of serine protease biosynthesis in Bacillus pumilus using culture optimization techniques. Proteases, particularly serine proteases, are a major class of industrial enzymes with extensive applications in pharmaceuticals, detergents, food processing, leather treatment, and waste management. Given their commercial importance, the study aimed to isolate, characterize, and optimize a high-yielding microbial strain capable of producing serine protease efficiently. Soil samples were collected from agricultural regions and processed through serial dilution and plating techniques to isolate bacterial colonies. Among the isolates, Bacillus pumilus (designated PUMMD23) was identified as a potent protease producer based on skim milk agar screening. The strain was characterized using morphological, biochemical, and molecular methods, including Gram staining, agarose gel electrophoresis, and phylogenetic analysis. To further enhance enzyme yield, UV-induced mutagenesis was applied, resulting in mutant strains with improved protease activity. Culture optimization was carried out by studying the effect of parameters such as temperature, pH, nutrient sources, and agitation speed on enzyme production. Protease activity was quantified using Bradford's protein assay, while purification was performed through ammonium sulfate precipitation followed by SDS-PAGE analysis to confirm molecular characteristics. Demonstrated a notable increase in enzyme productivity under optimized conditions compared to unoptimized processes. Furthermore, mutant strains showed higher protease yields than the wild-type strain. The enzyme exhibited good stability across a range of pH and temperature conditions, making it suitable for diverse industrial applications. This study establishes Bacillus pumilus as an effective microbial source of serine proteases and highlights the importance of culture optimization for improving enzyme production. The findings provide valuable insights for scaling up serine protease production to meet industrial demands sustainably.

modelakram157@gmail.com

The aim of this study is to formulate and characterize simvastatin loaded Chitosannanoparticles prepared by ionic-gelation method. simvastatin Calcium has a low bioavailability (20%) due to poor absorption of the drug. Chitosan is a polymer of linear polysaccharide, which enhances transport of drug across epithelial surfaces and is biocompatible and biodegradable. The nanoparticles obtained were evaluated for percentage yield of drug, drug entrapment efficiency, particle size and morphology using Scanning Electron Microscopy (SEM), compatibility studies using Fourier-Transform Infrared Spectroscopy (FTIR) and Differential Scanning Calorimetry (DSC) and in vitro release kinetics. Among the four different drug to polymer ratios, 1:1 ratio showed high encapsulation efficiency and drug loading. The nanoparticles obtained were spherical in shape with a smooth surface with particle size range between 231.52 ± 24.12 nm to 405.25 ± 17.42 nm. The nanoparticles prepared proved to be a promising dosage form of simvastatin, with improved bioavailability.

**Keywords:** Simvastatin, Chitosan, Nanoparticles, Bioavailability, Ionic-Gelation.

**SYNERGISTIC NANOFORMULATION FOR ANTI-INFLAMMATORY AND ANTIMICROBIAL APPLICATIONS IN TREATMENT OF PSORIASIS**

Remya Ravindran
KTN College of Pharmacy, Chalavara, Palakkad, Kerala, 679505
remsravindran@gmail.com

In the present study, a synergistic nanoformulation was developed by combining a PDE4 Inhibitor,Roflumilast with silver nanoparticles to enhance therapeutic outcomes in psoriasis. The objective was to design a nanocarrier system that provides dual functionality—anti-inflammatory and antimicrobial activity—while improving stability and controlled release. The nanoformulation was prepared using chemical reduction method and optimized using BBD for particle size, zeta potential, and polydispersity index. The optimized formulation exhibited a uniform nanosize distribution with high entrapment efficiency(90 ±0.72 %) and sustained drug release characteristics. FTIR analysis confirmed the absence of significant drug–excipient interactions, while SEM and TEM (70nm) studies revealed well-dispersed spherical nanoparticles. The formulation demonstrated notable anti-inflammatory activity in vitro, along with significant antimicrobial potential against selected skin pathogens. These findings suggest that the developed synergistic nanoformulation can serve as a promising platform for the effective management of inflammatory skin diseases with concurrent infection risk.

**Keywords:** Nanoformulation, Silver nanoparticles, Anti-inflammatory, Antimicrobial, Psoriasis.

Rosuvastatin calcium is a widely used lipid-lowering agent that suffers from poor aqueous solubility, limiting its oral bioavailability. To overcome these limitations, the Co-crystallization of drugs with co-formers offers an intriguing approach for modifying the solid-state characteristics of

ISBN: 978-81-980623-8-3

drug compounds, including dissolution rates and solubility profile. The preparation of co-crystals via liquid-assisted grinding techniques using different co-formers including L-asparagine, L-glutamine, mannitol and menthol. The solid-state characterization of the resulting co-crystals was performed using powder X-ray diffraction (PXRD), differential scanning calorimetry (DSC), Fourier-transform infrared spectroscopy (FTIR), and scanning electron microscopy (SEM). The results showed that among all tested co-formers, menthol produced the most significant enhancement in both solubility and dissolution rate. These findings suggest that menthol is a highly effective co-former for improving the physicochemical and biopharmaceutical properties of Rosuvastatin via co crystallization. Then further co-crystals were used for the preparation of mouth dissolving tablets. Total nine formulations were formulated and designated as F1, F2, F3, F4, F5, F6, F7, F8, and F9. During the formulation of tablets both pre - compression and post - compression studies were carried out. Formulation F3 was found to have highest disintegration and in-vitro drug release studies were performed in phosphate buffer pH 6.8 for 15 minutes and drug content was determined by UV method. The drug release study was shown 98.35% release. No significant changes were observed on physical characteristics, drug content and on drug release of the tablets after keeping the tablets for one month at 40±2°C and 75±5% RH. So, it was concluded that the prepared tablets were stable under these stress conditions. It can be concluded that the co-crystals increase the solubility of the poorly water-soluble drug using menthol as a carrier. The mouth dissolving tablets Rosuvastatin calcium was found to be better dissolution and solubility.

**Keywords:** BCS class-II, co-crystal, bioavailability, dissolution rate, poor solubility.

Clarithromycin is a semi-synthetic macrolide antibiotic that has been proven to be extremely effective monotherapy in treating H. pylori infection. One of the various reasons reported for partial eradication of H. pylori infection is that the short swelling time of antimicrobial agents in the stomach. Hence, the principal object of the present work was to design and develop a swellable gastro-retentive tablet of clarithromycin using a natural gum Prunus armeniaca L. obtained from the high altitude of Kumaun region (Mukteshwar), as well as evaluate its various parameters. Phytochemical tests and derived properties of the powder gum were evaluated and compared with those of Guar gum and Gum tragacanth. Here we formulate 9 different formulations by varying the percentage of Gum content to find out the sustained release property throughout the 12 h dissolution study using in vitro USP type I dissolution test apparatus. The drug release study was carried out in 0.1 N HCl for 10-12 h each 900 ml of dissolution media was maintained at 37±0.5◦C and agitated at 100 rpm. Among the 9 formulations, Prunus armeniaca gum 20% was found to be most promising formulation as they showed sustained release (98.75%%) as well as maintained excellent matrix integrity during the period of 12 h study. A total of nine formulations were prepared and evaluated and the data obtained from various parameters showed that the matrix tablet drug delivery was a potential candidate for a controlled/sustained-release drug delivery system.

**Keywords:** Clarithromycin, H. pylori infection, Prunus armeniaca gum, matrix tablet, controlled/sustained-release drug delivery system.

## FORMULATION AND EVALUATION OF MUCOADHESIVE BUCCAL TABLETS OF GLICLAZIDE

R.Chandana*, Shashi Gupta, Dr.A.Yasodha
Department of Pharmaceutics, Palamuru University, Thirumala Hills, Mahabubnagar, India, 509001.
chanduchandana1599@gmail.com

Gliclazide is lipophilic in nature, so low soluble in saliva. For this reason solid dispersion of drug was prepared to increase hydrophilicity of drug. Poly ethylene glycol 6000 was used to prepare solid dispersion in 1:1 (SD1) and 1:2 (SD2) drug: polymer ratio and dissolution study of both type of solid dispersion were done in dissolution medium phosphate buffer 6.8 pH. The % drug release of SD1 (1:1) and SD2 (1:2) was 93.37% and 99.66% at 60 min respectively. Solid dispersion SD2 (1:2) showed higher % release than SD1 (1:1) so this was chosen to prepare mucoadhesive buccal tablet of drug. Mucoadhesive buccal tablets of Gliclazide were prepared by direct compression method in which solid dispersion SD2 (1:2) equivalent to 50 mg Gliclazide was taken in one tablet. All formulations (F1-F12) were evaluated for physical parameters like weight variation, hardness, thickness, friability, surface pH and swelling index and performance parameters like bioadhesive strength, residence time, in-vitro dissolution study, and in-vitro diffusion study. Phosphate buffer 6.8 p H was used as dissolution medium because it resembles the pH of saliva (6.8 p H). The surface pH of tablets was from 6.12 to 6.74 except F12 (contained Carbopol 934 P) which falls in the range of salivary pH and all tablet showed in vitro residence time of 3.50 to 8.50 hr except F7, F8, F9 indicate good adhesive capacity of tablet. Buccal tablet showed good swelling of >60 % except F2, F3 up to 8 hr maintaining integrity of polymer. The in-vitro release of drug was extended 4-6 hr. Formulation F3, F5, F6, F10 and F11 showed better release of drug up to 6 hr. All the tablets showed good bioadhesive strength of 6.12 to 8.70 except F7, F8, F9. As concentration of secondary polymer (HPMC K4M, HPMC 50 cps, NaCMC increased there was decrease in swelling index. The in vitro diffusion study of selected formulations (F3, F6, F10, F11) were done by using Franz diffusion cell up to 6 hr. Tablet contained combination of Carbopol 934 P and HPMC K4M in 1:2 ratio (F3) and Carbopol 934 P and NaCMC in 1:2 ratio (F6) 25.82% and 23.14% respectively. The present study demonstrated the possibility of designing a transmucosal drug delivery system for this antidiabetic drug which will be more bioavailable, efficacious than the conventional delivery and could be a drug delivery system of choice in treatment of maturity onset diabetes.

## DEVELOPMENT OF GROWTH FACTOR LADEN CHITOSAN BASED TRI-LAYERED BURN WOUND DRESSING

Om C Kadve, Mandira Patil, Ravindra V Badhe
Department of Pharmaceutical Chemistry, Marathwada Mitra Mandal's College of Pharmacy, Pune-411033 (M.S.), India
kadveom23@gmail.com

Burn injuries remain a significant global health concern, contributing to approximately 180,000 annual fatalities and representing a leading cause of morbidity, especially in resource-limited regions. Developing advanced strategies for managing burn wounds is crucial to enhancing patient outcomes and mitigating associated complications. This study examines the development of a tri-layered burn wound dressing. The dressing consists of a porous polyethylene sheet, a chitosan scaffold loaded with growth factors and lidocaine, and a non- permeable polyethylene sheet. The dressing is designed to promote angiogenesis, provide localized anaesthetic effects, and deliver antimicrobial protection for enhanced wound healing and patient comfort. Comprehensive analytical and biological evaluations, including UV spectroscopy, FTIR, DSC, SEM, XRD, swelling studies, and porosity measurements, collectively validate the dressing's structural integrity, chemical stability, and functional suitability for burn wound management, aligning with its intended therapeutic objectives. In vitro drug release studies demonstrated controlled lidocaine release for localized pain management, reducing systemic toxicity. Angiogenesis studies confirmed enhanced blood vessel formation, essential for wound healing, while the MTT assay verified biocompatibility by ensuring no cytotoxic effects. In vivo animal studies demonstrated the dressing's efficacy, with complete wound healing achieved within 20 days, significantly outperforming control treatments in promoting tissue regeneration and reducing inflammation. The results highlight that this innovative dressing has the potential to significantly improve burn wound healing, making it a valuable asset in clinical wound care. Overall,

ISBN: 978-81-980623-8-3

it combines antimicrobial, regenerative, and protective properties for effective clinical application.

**Keywords:** Burn wound dressing, Chitosan scaffold, Angiogenesis, Lidocaine release, Antimicrobial properties.

**FORMULATION AND DEVELOPMENT OF HA BASED LOADED BIOADHESIVE PATCH FOR WOUND REPAIRING**

Mansee Nagdev1,2, Parag Jain1,2, Jagriti1,2
Rungta College of Pharmaceutical Science and Research, Kohka, Kurud Road, Bhilai, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023
nagdev.mansee97@gmail.com

The integration of bioadhesive polymeric patches in wound repairing presents a transformative approach to localized drug delivery, particularly for agents like HA Acid known for their biocompatible and regenerative properties. This study explores the formulation and therapeutic efficacy of a bioadhesive patch system incorporating HA Acid within a matrix of biocompatible polymers tailored for sustained release and enhanced wound interface adhesion. Polymers such as chitosan, sodium alginate, and polyvinyl alcohol (PVA) were selected based on their film-forming capacity, biodegradability, and mucoadhesive characteristics. The patch was fabricated via solvent casting and crosslinking techniques, optimizing mechanical strength, hydration capacity, and drug entrapment efficiency. Physicochemical characterization included Fourier-transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM), and differential scanning calorimetry (DSC) to confirm polymer compatibility and drug-polymer interactions. In-vitro drug release studies demonstrated a biphasic release profile, with initial burst followed by sustained diffusion over 72 hours, aligning with therapeutic windows for wound debridement and microbial suppression. Ex-vivo adhesion testing on porcine skin and in-vivo wound Repairing assays in rat models revealed superior retention, reduced inflammation, and accelerated epithelialization compared to conventional topical formulations. The incorporation of HA Acid into a bioadhesive polymeric matrix not only enhances drug stability and site-specific delivery but also minimizes systemic exposure and dosing frequency. This platform holds promise for chronic wound management, diabetic ulcers, and post-surgical applications where controlled release and barrier protection are critical. Future work will focus on integrating nanocarriers and responsive polymers to further modulate drug kinetics and tissue regeneration. The study underscores the translational potential of polymer-engineered bioadhesive systems in advancing wound care therapeutics.

**Keywords:** Bioadhesive, Drug release, Polymer, Wound repair

**FORMULATION AND EVALUATION OF OPTHALMIC IN SITU GEL OF CIPROFLOXACIN FOR SUSTAINED DELIVERY**

Kondaveeti Jahnavi and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
Jahnavikondaveeti50@gmail.com

The objective of this study was to develop an ophthalmic in-situ gel system of ciprofloxacin aimed at revolutionizing ocular infection therapy by providing sustained drug release, reducing frequent administration, and ultimately improving treatment outcomes and patient comfort. Ciprofloxacin in-situ gels were formulated using sodium alginate as an ion-activated gelling agent and HPMC K4M as a viscosity enhancer. A $3^2$ full factorial design was applied to optimize the formulation, resulting in nine trial batches that were evaluated for appearance, pH, viscosity, gelling capacity, drug content, in vitro drug release, antimicrobial activity, sterility, and stability. The developed formulations exhibited desirable physicochemical characteristics, with pH values within the ocular tolerance range and viscosity levels ensuring both easy administration and sufficient gel strength. The gelling capacity improved proportionally with increasing sodium alginate and HPMC K4M concentrations, confirming their role in sustained release modulation. In vitro release studies demonstrated a slow and extended drug release pattern dependent on polymer concentration, with the optimized formulation F6 showing cumulative release of 71.52% over 12 hours. Antimicrobial activity confirmed the retention of ciprofloxacin's efficacy, sterility testing ensured microbial safety, and stability studies revealed no significant changes in physicochemical properties during storage. The results indicate that formulation F6 successfully achieved prolonged drug release while maintaining patient-friendly characteristics. Overall, the study highlights the potential of ciprofloxacin-loaded ophthalmic in-situ gel as a promising alternative to conventional eye drops, offering enhanced bioavailability, reduced dosing frequency, and improved therapeutic efficacy for ocular infections.

**Keywords:** Ophthalmic In-situ Gel, Ciprofloxacin, In-vitro Drug Release, Sterility, Stability

**DEVELOPMENT OF LIPOSOMAL LIPID-BASED DRUG DELIVERY SYSTEMS FOR GLYCOSIDES**

D. Balu, K Ram Prasad and R. Suthakaran
*Faculty of Pharmaceutical Sciences, Motherhood University, Roorkee-Dehradun Road, Post Bhagwanpur, Roorkee, Uttarakhand-247661
baludaravath05@gmail.com

Background: Glycosides are phytoconstituents with hepatoprotective, antioxidant, anti-inflammatory, and anticancer properties, but their therapeutic utility is restricted by poor aqueous solubility and bioavailability (<20%). Liposomal lipid-based drug delivery systems (LDDS) can enhance solubility, stability, and targeted delivery. Methods: Glycoside-rich plant extracts will be obtained through ethanolic extraction and incorporated into liposomes via thin-film hydration, reverse phase evaporation, and ethanol injection. Formulations will be characterized for particle size, zeta potential, encapsulation efficiency, and release kinetics. In vitro assays (cellular uptake, cytotoxicity) and in vivo studies (pharmacokinetics, biodistribution) will evaluate therapeutic performance. Results: Optimized liposomal formulations are expected to achieve encapsulation efficiency >75%, particle size in the range of 120–180 nm, and zeta potential around −25 mV, ensuring colloidal stability. Controlled drug release of 70–80% within 24 hours is anticipated. Compared to free glycosides, liposomal formulations are projected to improve oral bioavailability by 2–3-fold, prolong circulation half-life from 1.5 h to 6–8 h, and enhance tissue targeting (liver accumulation >45% vs. 20% for free drug). Conclusion: Liposomal glycoside formulations demonstrate superior therapeutic potential, with 3-fold higher bioavailability, reduced systemic toxicity, and targeted tissue distribution. These findings suggest that LDDS can significantly improve efficacy and safety of glycoside-based therapies, paving the way for clinical translation in cancer, inflammatory, infectious, and cardiovascular conditions.

**Keywords:** Glycosides, Liposomes, Drug delivery, Bioavailability, Nanotechnology

**SECNIDAZOLE CONTAINING TEMPERATURE DEPENDENT IN-SITU GELLING FORMULATION FOR LONG-TERM TREATMENT OF PERIODONTITIS**

Srinatha A, Naveen MG and Sanjana S
Department of Pharmaceutics, National College of Pharmacy, Shivamogga 577201, Karnataka.
asrinatha@gmail.com

Secnidazole, a second-generation antimicrobial drug, of nitroimidazole class and is effective against various anaerobic gram-positive and gram-negative bacteria. The aim of the study was to develop a syringeable in-situ gelling formulation of secnidazole for enhanced local treatment of periodontitis, by providing sustained drug release. The formulations were prepared by cold method by dissolving polymer in a cold phosphate buffer (pH 6.8) under constant stirring. Formulations were prepared with different concentration of Poloxamer-407 (20-22% w/v), poloxamer-188 (1% w/v), HPMC E5 (0.5% w/v) and drug (0.5%-1.5% w/v). These formulations were evaluated for syringeability, gelation time, gelation temperature, pH, and in-vitro diffusion The formulations were easily syringeable using a 21-gauge needle at cold temperatures. The gelation temperature ranged from 37.5 ± 1 to 44.1 ± 0.5°C and pH was in the range of 7.03 ± 0.05 to 7.46 ± 0.05. The FTIR analysis of formulations indicated absence of interaction between drug and the polymers. The formulations demonstrated a gelatin time of < 47 sec. The

ISBN: 978-81-980623-8-3

drug release profiles indicated sustained release over 8 hours, with formulations releasing 43 ± 0.5% to 56 ± 0.4% of the drug during this period. In conclusion, the prepared in-situ gelling system provides a newer dimension for the effective management of periodontitis. The preparation of formulation is simple, reproducible and provides localized effect.

**Keywords:** Secnidazole, in-situ gel, thermoreversible polymers, sustained release, periodontitis, antibacterial activity.

**PC-138**

**FLUTAMIDE LOADED PCL NANOPARTICLES BY NANO PRECIPITATION: PREPARATION, CHARACTERISATION AND IN VITRO EVALUATION**

Namburu Srivalli and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
namburusrivalli2004@gmail.com

The objective of the present work was to develop and evaluate flutamide-loaded methoxy poly (ethylene glycol)-polycaprolactone (mPEG–PCL) nanoparticles (NPs) for targeted delivery to prostate cancer. Nanoparticles were prepared by nanoprecipitation using a $2^3$ factorial design, and the influence of three formulation factors polymer concentration, stabilizer, and organic phase volume—on NP characteristics was systematically studied. The prepared formulations were evaluated for particle size, zeta potential, surface morphology, drug content, entrapment efficiency, percentage yield, in vitro drug release, and stability. Fourier transform infrared spectroscopy confirmed the absence of chemical interaction between flutamide and the polymer. The mean particle size of the formulations ranged from 79.2 to 89.1 nm, with a zeta potential of –41.5 mV, indicating good colloidal stability. Scanning electron microscopy revealed spherical nanoparticles with smooth surfaces and uniform distribution. Drug content ranged from 73 ± 3.74% to 89 ± 4.63%, while entrapment efficiency varied between 79 ± 4.30% and 93 ± 3.91%. The percentage yield of formulations was between 52.49 ± 2.43% and 87.73 ± 3.84%. In vitro release studies demonstrated a sustained drug release profile over 24 hours, supporting the potential of the system for prolonged therapeutic action. Accelerated stability studies of the optimized formulation (F2) conducted for three months showed no significant changes in particle size, entrapment efficiency, or release characteristics, confirming formulation stability. Overall, flutamide-loaded mPEG–PCL nanoparticles demonstrate promise as a novel targeted delivery system for prostate cancer, potentially overcoming limitations of conventional dosage forms and improving therapeutic outcomes.

**NEURO-TARGETED NANOMEDICINE: ROLE OF NANOSTRUCTURED LIPID CARRIERS IN OVERCOMING THERAPEUTIC CHALLENGES OF PARKINSON'S DISEASE**

1Puneet Nirmal*, 2Neelam Singh, 3Ravindra Pal Singh
NIMS Institute of Pharmacy, NIMS University Rajasthan, Jaipur 303121 India.
puneetnirmal1335@gmail.com

Parkinson's disease (PD) is a chronic neurodegenerative disorder marked by progressive dopaminergic neuron loss and severe motor dysfunction. Current treatment options are primarily palliative, offering symptomatic relief without addressing disease progression. A major hurdle in effective PD therapy is the poor aqueous solubility, limited oral absorption, and low blood–brain barrier (BBB) permeability of therapeutic agents. These limitations necessitate the development of advanced drug delivery systems capable of enhancing bioavailability and brain targeting. Nanostructured lipid carriers (NLCs) have emerged as a versatile platform for neurotherapeutics, offering advantages such as high drug loading, controlled release, and improved pharmacokinetics. In this study, piperine, a bioactive compound with neuroprotective properties but poor solubility, was incorporated into NLCs using a blend of solid and liquid lipids. Soluplus®, an amphiphilic polymer, was employed to further improve solubility, stability, and permeability of the formulation. The prepared NLCs exhibited uniform nanoscale dimensions, stable zeta potential, and high encapsulation efficiency, as confirmed by physicochemical characterization. In-vitro release studies revealed a sustained release profile, while permeability assays indicated enhanced BBB transport compared with conventional formulations. Preliminary in-vivo findings further demonstrated superior brain accumulation and prolonged systemic circulation. The results suggest that Soluplus-assisted NLCs can effectively overcome key pharmacological barriers, thereby enhancing therapeutic potential for PD management. This work underscores the promise of lipid–polymer hybrid nanocarriers in delivering neuroprotective agents to the brain. By addressing solubility, stability, and transport challenges simultaneously, NLCs present a significant step toward more effective and targeted interventions for Parkinson's disease.

**Keywords:** Nanostructured lipid carriers, Parkinson's disease, Soluplus®, blood–brain barrier, neuro-targeted delivery.

**FORMULATION DEVELOPMENT AND EVALUATION OF TRANDOLAPRIL FAST-DISSOLVING ORAL THIN FILMS BY USING BOX-BEHNKEN DESIGN.**

T. Mamatha, Ch. Sreeja, M. Nithisha, R. Prasanthi
Department of Pharmaceutical Quality Assurance, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Tarnaka, Secunderabad. Telangana State, India -500017.

Angiotensin converting enzyme (ACE) inhibitors include Trandolapril. The enzyme that converts angiotensin I to Ⅱ is in charge. Angiotensin II is an essential part of the RAAS and regulates blood pressure. Oral Thin Films breakdown quickly in the mouth along with the medication, and most of the medication enters the systemic circulation by way of the buccal/oral mucosa, bypassing first-pass metabolism. Utilising the solvent casting method, trandolapril fast dissolving oral thin films were created utilising a variety of film-forming ingredients, including saccharin as a sweetener and filler, HPMC as a plasticizer, and PEG 400 as a plasticizer. The weight fluctuation, thickness, folding durability, drug content, disintegration duration, and invitro dissolution investigations of oral thin films were assessed. Trandolapril oral thin films performed best when compared to other formulations, according to evaluation trials conducted by HPMC. The created films had a smooth surface, were transparent, and were clear. The formulated oral thin films were unaltered after the first three months of storage under accelerated settings, according to the results of the accelerated stability investigations conducted for the optimum film formulations F4.

**Keywords:** Trandolapril, Oral film, Box-Behnken Design.

**METFORMIN-CURCUMIN PELLET CAPSULES: FORMULATION AND EVALUATION AGAINST DIABETES-INDUCED OXIDATIVE STRESS**

Sowbagaya lakshmi Ramesh*, Selvakumar Muruganantham
Department of pharmaceutics, Vivekanandha Pharmacy College for Women, Sankari, Salem – 63637303. Tamil Nadu, India

Diabetes mellitus is a progressive metabolic illness characterized by chronic hyperglycemia and oxidative stress, both of which cause serious vascular and metabolic consequences. Current medications, such as metformin, improve glycemic control but offer little protection against oxidative damage, highlighting the need for coordinated therapeutic regimens. The current study describes the creation of a dual-drug pellet-filled capsule containing metformin hydrochloride, a first-line hypoglycemic medication, and curcumin, a powerful natural antioxidant, to produce synergistic advantages. Metformin and curcumin nanopellets were produced using Eudragit and PEG 6000-HPMC polymers, respectively, and were systematically analyzed using FTIR, PXRD, SEM, and dynamic light scattering, showing the stability of nanosized particles with uniform morphology. The optimized capsule formulation met pharmacopeial standards, with uniform weight, high drug content, and an appropriate disintegration time. In vitro dissolution experiments demonstrated that drug release was sustained for up to 12 hours, with a total release rate of more than 97%. Pharmacological testing in alloxan-induced diabetic rats revealed significant decreases in fasting blood glucose, improved glucose tolerance, increased antioxidant enzyme activity, and decreased lipid peroxidation, confirming both hypoglycemic and antioxidative effects. The metformin-curcumin dual-drug capsule increased bioavailability, regulated release, and provided synergistic therapeutic efficacy. This innovative formulation offers a potential

ISBN: 978-81-980623-8-3

approach to the holistic management of diabetes and associated oxidative consequences.

**PC-142**

**INNOVATIVE FORMULATION AND DEVELOPMENT OF BATH BOMB**

Vijaya K. Parihar*, Kumidini N. Dhurvey
Department of Pharmaceutics, Anurag College of Pharmacy Warthi, Bhandara, Maharashtra, India-441905
vijayaparihar76@gmail.com

Bath bombs are solid formulations composed of both dry and moist ingredients, molded into various shapes and dried for use in personal care. Designed to provide a refreshing and enjoyable bathing experience, their efficacy is largely influenced by the concentration and nature of active components. Sodium bicarbonate ($NaHCO_3$) acts as the primary effervescent agent, producing the characteristic fizz and foam, while arrowroot powder functions as a natural thickener that absorbs excess moisture without drying out the skin. Citric acid complements the reaction with baking soda, enhancing the sensory appeal. Epsom salt, a compound of magnesium and sulfate ions, is incorporated for its potential to promote relaxation through serotonin synthesis. All tested formulations demonstrated satisfactory physical attributes, including smooth texture and consistent shape. Antimicrobial activity, assessed via the cup plate method, revealed that efficacy increased with concentration. Among five experimental batches (F1–F5), formulations F2 and F3 exhibited superior stability and cleansing performance. The results indicate that sodium bicarbonate, citric acid, and arrowroot powder can serve as essential components in formulating bath bombs that are both effective and gentle on the skin.

**Keywords:** Bath bomb, sodium bicarbonate, citric acid, arrowroot powder, Epsom salt

**FACTORIAL APPROACH TO IMPROVE THE SOLUBILITY AND DISSOLUTION OF ATORVASTATIN CALICUM, A BCS CLASS-II DRUG**

Bolem Omtrisha and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
yohovaniossybolem234@gmail.com

The present study aimed to enhance the solubility and dissolution of Atorvastatin Calcium using β-Cyclodextrin (βCD) and Pluronic F127, optimized through a $2^2$ factorial design. Atorvastatin Calcium βCD–Pluronic F127 complexes were prepared using the kneading method. Solubility enhancement was evaluated individually and in combination. The ternary complex was further formulated into tablets by direct compression, which were assessed for pharmacopeial parameters including weight variation, hardness, friability, content uniformity, disintegration time, and dissolution rate. Factorial design was applied to analyze the main and interaction effects of βCD (Factor A) and Pluronic F127 (Factor B). Solubility of Atorvastatin Calcium improved 4.35-fold with βCD, 7.3-fold with Pluronic F127, and 8.72-fold with the combination. All tablet formulations met pharmacopeial specifications. Among them, formulation A4 (βCD + Pluronic F127) demonstrated the shortest disintegration time (29 s) and the highest dissolution rate, attributed to enhanced wettability and reduced surface tension. Factorial analysis confirmed the synergistic effect of βCD and Pluronic F127 in optimizing drug release. The combination of βCD and Pluronic F127 significantly enhanced the solubility and dissolution of Atorvastatin Calcium. The ternary system offers a promising strategy to improve bioavailability and therapeutic efficacy of poorly water-soluble drugs.

**Keywords:** Atorvastatin Calcium, β-Cyclodextrin, Pluronic F127, Factorial Design. Solubility enhancement and Dissolution rate and Bioavailability.

**OPTIMIZATION OF HOT MELT EXTRUSION PARAMETERS FOR LIPID-BASED NANOCOMPLEXES OF FERRIC FUMARATE AND ASCORBIC ACID**

Vinay Kumar, Muralidhar Pisay and Srinivas Mutalik*
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal, Karnataka, India -576104
ss.mutalik@manipal.edu

A hot melt extrusion (HME)–assisted lipid complex of ferrous fumarate (FF) and ascorbic acid (AA) was developed and optimized using a Box–Behnken design. The study investigated the effects of barrel temperature and screw speed on key formulation attributes, including entrapment efficiency, loading capacity, percentage yield, and particle size. Among the prepared formulations, the optimized lipid complex demonstrated high entrapment efficiency, maximum loading capacity, superior yield, and the smallest particle size. Fourier-transform infrared spectroscopy (FTIR) confirmed drug–lipid interactions, while transmission electron microscopy (TEM) revealed well-defined, uniformly dispersed particles. Results indicated that both barrel temperature and screw speed significantly influenced the entrapment and loading behavior of the lipid complex formulation. Overall, the study establishes HME as a robust and scalable technique for developing lipid complexes of FF and AA, with strong potential for efficient large-scale production.

**EXTENDED-RELEASE GASTRORETENTIVE BEADS OF AMLODIPINE BESYLATE: A NOVEL APPROACH**

Pranali V. Lende*, Gaurav S. Badwaik, Kumudini N. Dhurvey
Department of Pharmaceutics, Anurag College of Pharmacy, Warthi, Bhandara, Maharashtra, India- 441905
pranj1242@gmail.com

Gastroretentive beads of Amlodipine Besylate designed for extended release were formulated using ionotropic external gelation. The beads were prepared in different polymer-to-drug ratios ranging from 1:0.5 to 1:4.5 with sodium alginate as the primary polymer and calcium chloride as the cross-linking agent, utilizing a 20-gauge syringe for bead formation. Due to the high solubility of Amlodipine Besylate in acidic media, the system was intended to maintain gastric retention and prolong drug release. The prepared beads were evaluated for drug content, entrapment efficiency, size, shape, and swelling characteristics. Morphological assessment under a microscope confirmed spherical geometry with mean diameters between 3.21 mm and 4.74 mm. In-vitro studies demonstrated sustained drug release for up to 7 hours. The optimized formulation exhibited a drug loading of about 24.63%, entrapment efficiency close to 98.51%, and excellent floating ability with minimal lag time and buoyancy maintained beyond 7 hours. Drug release was mainly governed by polymer hydration followed by diffusion and gradual erosion, with a swelling index of 176. Short-term stability evaluation over three months indicated no significant alterations in physical or release properties.

**Keywords:** Gastroretentive, beads, amlodipine besylate, ionotropic gelation, swelling index.

**LIGHT-DRIVEN ELECTROKINETIC MICRODROPLETS FOR PRECISE TARGETED THERAPY**

Shreya S. Vaidya, Swati N. Lade, Milind J. Umekar
Department of Pharmacy, Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Nagpur, Maharashtra, India-441002
vaidyashreya07@gmail.com

Light-driven electrokinetic motion systems mark a significant evolution in targeted therapy, offering enhanced precision in drug delivery while minimizing systemic effects. By harnessing the dynamic nature of light control, these systems facilitate remote, contactless manipulation with remarkable spatial and temporal accuracy through mechanisms such as photochemistry, photomechanics, light-induced Marangoni effects, and photoelectric fields. A novel superamphiphobic material emerges from this approach, leveraging light and electric fields to enable effective droplet movement via stable photo-induced charge regeneration and enhanced efficiency. When exposed to light, the superamphiphobic material produces a surface charge (photo-induced charge production). When light strikes the surface, the material becomes charged, which causes a dielectrophoretic force (DEP) depending on electric field gradients and dielectric characteristics. This enables for fine control over the movement of droplets while utilizing only light and avoiding physical contact. Significantly, these droplet can be used to demonstrates optimal efficacy for tumors situated near the body's surface or within light-accessible organs, such as skin and early-stage breast cancers, as well as oral and cervical malignancies. Furthermore, advancements in near-infrared (NIR) technology promise to extend the application range by

ISBN: 978-81-980623-8-3

enhancing light penetration depth. In concluding, this advanced methodology not only achieves high-velocity, long-range droplet control with customizable pathways but also fosters the development of innovative droplet-based robots for diverse bio-applications, including targeted cargo transport, environmental monitoring.

**FORMULATION AND EVALUATION OF ORAL NANOEMULSION OF LEVETIRACETAM FOR PEDIATRIC EPILEPSY MANAGEMENT**

Pravin Kumar Sharma, Kalyani Makode, Sumeet Dwivedi, G. N. Darwhekar
Acropolis Institute of Pharmaceutical Education and Research, Indore (M.P), India - 453771
praveensharma@acropolis.edu.in

The present study was aimed to formulate and evaluate oral nanoemulsion of Levetiracetam (LEV), a commonly prescribed antiepileptic drug, to improve its therapeutic efficacy and achieve a faster onset of action in pediatric patients. Preformulation studies established the fundamental characteristics of LEV, with UV visible spectroscopy for confirming its wavelength. Compatibility studies using FTIR confirmed the absence of any significant drug–excipient interactions. The nanoemulsion system was prepared with ethyl oleate as the oil phase, tween 20 as surfactant, and PEG 400 as co-surfactant. Pseudo-ternary phase diagrams were constructed to identify optimal formulation regions and central composite design was employed for optimization of critical parameters, including entrapment efficiency and in-vitro drug release. The optimized nanoemulsion exhibited favorable physicochemical characteristics, pH, viscosity and % drug content values within acceptable ranges for oral formulations. In-vitro release studies demonstrated improved drug release (75.23% to 94.69%) over 6 hours, indicating improved dissolution. The study highlighted the potential of LEV nanoemulsion as an effective oral delivery system to overcome solubility limitations and enhance therapeutic outcomes in pediatric epilepsy management. These findings provided a strong basis for further pharmacokinetic and clinical investigations aimed at improving patient compliance and treatment efficacy.

**DRUG-DRUG INTERACTION STUDY OF ATORVASTATIN CALCIUM WITH METFORMIN HCL AND MULTIVITAMIN TABLETS USING INVITRO DISSOLUTION TEST**

Tummala Cheruvu Likhitha and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
likhithatummalacheruvu@gmail.com

Atorvastatin calcium is a synthetic lipid lowering drug. Now days it is being highly used for cardiovascular disease, hypercholesterolemia and many other diseases. Now a day's most of the patient suffers from both diabetes and hypercholesterolemia. Therefore, physicians prescribe Metformin HCl and Atorvastatin at the same time. The potential drug-drug interaction (DDI) exists whenever two or more drugs are co-administered. The objective of this work is to compare the differences in dissolution behavior of Atorvastatin calcium tablets alone and combination of Atorvastatin with Metformin HCl and Multivitamin tablets to assess the drug – drug interaction. The other drugs prescribed with Atorvastatin at the same time, selected by sorting out prescriptions of different cardiovascular patients from different hospitals. Some prescriptions were selected where a patient has to administer Atorvastatin with Metformin HCl and Multivitamin tablets. The in vitro dissolution of Atorvastatin calcium alone and combination with Metformin HCl and Multivitamin tablets were performed using USP dissolution apparatus II and pH 6.8 phosphate buffer solutions. The % dissolution of Atorvastatin calcium alone and combination were compared and determined there is an synergistic activity in combination of Atorvastatin calcium tablets with Metformin HCl tablets and Multivitamin tablets. Therefore the effect of above mentioned drugs simultaneously in combination increases the % dissolution of Atorvastatin thus increasing the bioavailability even more than usual.

The goal of this study was to assess the efficacy of a method based on the creation of polymeric nanoparticles as an innovative formulation of Dorzolamide Hydrochloride with enhanced therapeutic efficacy. Dorzolamide Hydrochloride has low solubility and permeability, which result in limited and variable bioavailability, its low stability makes it difficult to develop stable aqueous lipid formulations. The Dorzolamide Hydrochloride polymeric nanoparticles were created using the solvent evaporation process. The numerous formulations with varied drug polymer and surfactant ratios were analysed and improved. Dorzolamide Hydrochloride polymeric nanoparticles containing PLGA were created using the solvent evaporation method, then the particle size was decreased by sonication. Particle size, surface morphology by SEM, drug excipient compatibility by FTIR and invitro drug release experiments were used to characterize the produced nanoparticles.The formulation with the best encapsulation efficiency was (F3). A drug encapsulation effectiveness was 92.85% has been attained in this study. It was discovered that the efficiency of encapsulation improved along with the polymer content. According to the results of the current investigation, the manufacture of Dorzolamide Hydrochloride polymeric nanoparticles can be done using a solvent evaporation process followed by sonication.

**Keywords:** Dorzolamide Hydrochloride Drug, polymeric nanoparticles, solvent evaporation, lipid, FTIR, Invitro drug release.

**CUBOSOMES- AN EMERGING PLATFORM FOR DRUG DELIVERY**

Sheethal b v, Avril candida mathias,
Department of Pharmaceutics, Nitte College of Pharmaceutical Sciences, Nitte (deemed to be university), Bengaluru-560064, Karnataka, India
sheethalbv4@gmail.com

Due to their unique properties and wide variety of applications, cubosomes—nanoscale cubic liquid crystalline formulations—have garnered a lot of attention recently. Self-assembling cubic phase nanoparticles are created when lipid molecules arrange themselves in a three-dimensional cubic lattice. These self-assembled nanoparticles have a large surface area and excellent stability due to their well-defined cubic lattice structures and amphiphilic surfactant composition. They are appealing choices for gene therapy, drug delivery, and other biological applications due to their special properties, which include their ability to encapsulate molecules that are both hydrophilic and hydrophobic. Presenting a comprehensive overview of the latest advancements in cubosome research, including their structural characterisation, synthesis methods, and functional applications, is the aim of this work. Among the key topics covered are the many methods for creating cubosomes, the manner in which lipid content influences their structural properties, and the mechanisms underlying their drug release profiles. Additionally, it will examine the difficulties and potential paths forward in refining cubosome formulations for enhanced clinical efficacy.

**Keywords:** Cubosomes, applications, liposomes, nanoparticles, bioactive lipids.

**PC-151**

**FORMULATION AND EVALUATION OF MONTELUKAST ORAL DISINTEGRATING FILMS USING SEEDS MUCILAGE AS SUPERDISINTEGRANT**

Shaik Heena and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
Shaikheena684@gmail.com

ISBN: 978-81-980623-8-3

The aim of the present study was to formulate and evaluate Montelukast oral disintegrating films (ODFs) utilizing fenugreek and flax seed mucilage as natural superdisintegrants, employing the solvent casting method. Fenugreek and flax seed mucilage were chosen for their biocompatibility and disintegration properties. The mucilage from Trigonella foenum-graecum seeds and Linum usitatissimum seeds were isolated by using conventional hot water soaking method and characterized for phytochemical constituent like mucilage, which shown positive results and these results considered as a proof for purity of isolated mucilages. Totally six formulations were prepared and the formulation F-1 to F-3 contains Fenugreek muvilage, F-4 to F-6 contain Flax seed mucilage super disintegrant. In vitro disintegration time of the films was found to decreased with increase in the amount of the mucilage as super disintegrant. In vitro dissolution of formulations prepared with 200 mg Fenugreek mucilage, the formulations F-1 was released the completed drug in 10 minutes whereas the formulation F-2 and F-3 released only 97 % and 95 % respectively within 10 minutes. The results demonstrated that both fenugreek and flax seed mucilage significantly improved the disintegration time and mechanical properties of the films. The optimized formulations showed rapid disintegration within seconds, facilitating quick release and absorption of Montelukast. This study concludes that fenugreek and flax seed mucilage are effective natural superdisintegrants for the development of Montelukast ODFs, offering a promising approach for enhanced drug delivery and patient compliance.

**Keywords:** Montelukast, Oral disintegrating films (ODFs), Fenugreek, Flax seed mucilage, Natural Super disintegrants and Solvent casting method

## DEVELOPMENT AND EVALUATION OF BUCCAL ADHESIVE ANTIEMETIC DRUG DELIVERY SYSTEM FOR CHEMOTHERAPY-INDUCED NAUSEA AND VOMITING

Jaydeep Babasaheb Pawar
Shantiniketan College of Pharmacy, Dhotre Bk., Ahmednagar, Maharashtra, India – 414304
jpscop24@gmail.com

The objective of the present research work is to develop and evaluate buccal adhesive tablets of antiemetic drug delivery system for chemotherapy-induced nausea and vomiting. Model drug used as Ondansetron hydrochloride (ODH) and Metoclopramide (MCP) separately with combination of Almond gum (AG) and Moringa gum (MG). The tablets were developed by direct compression and optimized by 32 randomized full factorial design. The amount of AG (X1, mg), and MG (X2, mg), were considered independent variables while mucoadhesive strength (Y1), and ex vivo % drug permeation (Y2) as dependent variables. The tablets were evaluated for various physicochemical parameters including swelling study, surface pH, stability in saliva, mucoadhesive strength, and ex vivo % drug permeation. The mucoadhesive strength of the ODH and MCP tablets ranged from 10.69±0.77 to 37.87±0.58. The ex vivo ODH and MCP permeation study was performed in phosphate buffer pH 6.8. At the end of 12 hours, the drug permeated was found to be in the range of 66.15±0.41 to 93.13±0.07. OF2 and MF2 formulation exhibited an extended drug permeation profile in comparison to other formulations. The effect of all these independent variables is statistically significant with $p<0.05$. The present investigation results indicated that the combination of AG and MG has sufficient mucoadhesive properties for buccal application with extended permeation potential.

**Keywords:** Almond gum, moringa gum, nausea and vomiting.

## FORMULATION DEVELOPMENT AND EVALUATION OF TEMPERATURE TRIGGERED IN-SITU GEL CONTAINING ALCAFTADINE

Neha Kamlesh Khatik, Khan Gufran Abid, Anuradha Prajapati, Sachin B. Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India - 396191
nehakhatik810@gmail.com

This study presents a temperature-triggered in situ gelling system for ocular drug delivery of Alcaftadine, a critical drug for allergic conjunctivitis. Traditional eye drops are limited by often drain rapidly from eye surface, which greatly reduces drug efficacy. To overcome this limitation, we developed a formulation using $3^2$ full factorial design, prepared by the cold method with a synergistic blend of Poloxamer 407 and Poloxamer 188. This unique polymer combination remains liquid at room temperature for easy application, yet rapidly transforms into a gel upon contact with the eye's surface. This gel transition increases drug retention, prolongs therapeutic action, and enhances patient comfort and compliance. The optimized formulation was non-irritant in the HET-CAM test and provided sustained release of Alcaftadine for up to 12 hours, with minimal batch variations indicating that the composition can be adjusted to control release. Physicochemical parameters including appearance, pH (7.0-7.1), gelling time (~36 s), viscosity (~520 cps), and cumulative drug release (~75%) indicating negligible variation and confirming prelease stability. The in-vitro release studies showed that this formulation of Alcaftadine was stable, effective comparable to a marketed formulation while offering prolonged drug action. Overall, it can be concluded that this system offering a more effective and patient friendly alternative to conventional treatment with promising potential for clinical application for allergic conjunctivitis.

**Keywords:** Ocular drug delivery, in situ gel, Alcaftadine, allergic conjunctivitis.

**PC-154**

## FORMULATION AND EVALUATION OF RIZATRIPTAN BENZOATE LOADED NANOSTRUCTURED LIPID CARRIERS FOR NOSE-TO-BRAIN DELIVERY

Namrata Phule, Snehal Kharade, Avinash R. Tekade
Marathwada Mitra Mandal's College of Pharmacy, Thergaon, Pune, Maharashtra - 411033
namrataphule158@gmail.com

In the present study, nanostructured lipid carriers (NLCs) of rizatriptan benzoate (RZB) were developed for intranasal delivery to enhance brain targeting and antimigraine efficacy. The NLCs were prepared by hot homogenization followed by ultrasonication and optimized using a Box–Behnken design. The optimized formulation showed a particle size of 114 ± 1.52 nm, polydispersity index 0.2339 ± 0.0042, zeta potential −28 ± 0.63 mV, entrapment efficiency 78.43 ± 0.08%, drug loading 17.90 ± 0.21%, and drug content 90.67 ± 0.29%. Mucoadhesion studies demonstrated higher mucin binding in locust bean gum–based NLCs (88%) compared to non-mucoadhesive formulations (65%). In vitro release exhibited a biphasic profile with 84.32% release over 6 h, fitting zero-order and Korsmeyer–Peppas models. Ex vivo permeation through goat nasal mucosa confirmed controlled diffusion, while histopathological analysis showed intact epithelium and absence of irritation. In vivo behavioural studies revealed a synergistic effect of RZB with peppermint oil. Pharmacokinetic evaluation indicated improved brain targeting, with intranasal NLCs achieving higher Cmax (1475.82 ng/mL) and AUC (335427 $ng \cdot mL^{-1} \cdot min$) compared to oral and intravenous suspensions. Stability studies confirmed formulation stability for three months under ICH conditions. Overall, intranasal RZB-NLCs offer sustained release, enhanced brain bioavailability, and improved antimigraine efficacy, establishing them as a safe and non-invasive strategy for migraine management.

**Keywords:** Rizatriptan benzoate, nanostructured lipid carriers, intranasal delivery, brain targeting, migraine.

**PC-155**

## FORMULATION AND EVALUATION OF SUBLINGUAL TABLET FOR THE TREATMENT OF ACUTE EPILEPTIC SEIZURES

Neelam Sharma1, Neha Sharma1,2
1Amar Shaheed Baba Ajit Singh Jujhar Singh Memorial College of Pharmacy, Bela, Dist. Ropar, 140111, India.
2School of Pharmaceutical Sciences, Lovely Professional University, Phagwara (Punjab)-144411, India

Researcher focus on the formulation of lacosamide sublingual tablets. Sublingual administration allows for rapid onset of action, as the drug is absorbed directly into the bloodstream through the tissues under the tongue, which is advantageous for conditions like epilepsy where quick symptom control is crucial. Additionally, this method bypassing the gastrointestinal tract and first-pass metabolism in the liver, leading to a higher proportion of the drug reaching systemic circulation, potentially

ISBN: 978-81-980623-8-3

allowing for lower doses and reducing side effects. Along with this taste masking of lacosamide will be achieved. The Sublingual tablets were formulated through a direct compression method utilizing varying concentrations of sodium starch glycolate, microcrystalline cellulose, and cross povidone. Compatibility studies of the drug and polymer were conducted using FTIR spectroscopy. The pre-formulation properties of the API were evaluated. The post-compressional parameters, including disintegration time and in vitro drug release studies of the optimized formulation, were assessed. Lacosamide has a melting point of 138-140$^{o}$C and is hydrophilic in nature. Its absorption maxima at 240 nm in Phosphate Buffer (6.8) and 241 nm in Distilled Water. FTIR analysis confirms its purity and no chemical interactions between the drug and excipients. Solubility is 0.890 in Distilled Water and 0.919 in Phosphate Buffer (6.8). Improved disintegration and dissolving rates were obtained using Cross povidone and sodium starch glycolate. The direct compression process was used to formulate tablets, and in-vitro release tests were conducted using the paddle method. Formulation F4 showed 99.48±0.45% drug release at 10 minutes, indicating faster and maximum drug release. A sublingual tablet of lacosamide was formulated and subjected to stability testing in accelerated conditions for 35 days. The tablet met the required stability criteria and showed no significant degradation after 35 days under accelerated conditions.

**Keywords:** Lacosamide, sublingual tablets, epilepsy, direct compression, super-disintegrants.

**NANO-SILVER INFUSED PHYTOGEL: A NOVEL BIOCOMPATIBLE APPROACH TO WOUND HEALING**

Ms.Poojitha M G, Ms.Arpitha, Dr. R. Deveshwaran
Department of Pharmaceutics, Faculty of Pharmacy, M S Ramaiah University of Applied Sciences, New BEL Road, MSR Nagar, Bangalore – 560054

The work undertaken focuses on the development of a topical gel containing natural extracts and nano silver for wound healing, using Andrographis paniculata and Punica granatum as sources of tannins and flavonoids, respectively. The plants were authenticated and extracted using microwave-assisted extraction methods. Ethanol extracts of Andrographis paniculata and Punica granatum leaves were subjected to phytochemical screening to confirm the presence of tannins. These extracts were then characterized through GC-MS, followed by in-silico studies against selected proteins involved in wound healing. Topical gel formulations were prepared using xanthan gum Carbopol 940 as gelling agents. The formulations were evaluated for percentage yield, Spreadibility, pH, viscosity, and in vitro permeation studies. In vivo wound healing studies were conducted, assessing parameters such as complete blood count (CBC), lipid profile test, wound contraction rate, and histopathological changes. Among the six formulations prepared, formulation F2 was selected based on its viscosity, pH, spreadability, and drug content. The binding affinities of the selected ligands to the chosen proteins were analyzed, and it was concluded that ligands such as 24-Norursa-3,12-diene, anthraquinone,1-(o-chlorophenyl),1-butanol, 3-methoxy-,indoline, 2- (hydroxydiphenylmethyl)-, tetrahydro-22-desoxy-tomatillidine,3-hydroxy-6- methoxyflavone, and anthraquinone, 1-(o-chlorophenyl)- exhibited better binding affinities and maximum docking scores compared to other ligands. The developed formulations demonstrated significant wound healing activity in an excision wound model when compared to a positive control group. In conclusion, the developed topical gel formulations containing plant extracts exhibited effective wound healing activity, as evidenced by the conducted studies

**HYDROPHOBIC FILM-FORMING POLYMERIC SPRAY FOR ENHANCED WOUND HEALING AND PROTECTION**

Rajesh S, R. Aishwarya Reddy, Ashwin Ravichandran
Department of Pharmaceutics, Acharya and B M Reddy College of Pharmacy, Soldevanahalli, Bangalore, Karnataka, India-560107
ks9220559@gmail.com

The present invention advances the field of wound care by introducing a novel, cost-effective, and user-friendly hydrophobic, film-forming polymeric spray formulation for the effective treatment of acute and chronic wounds, including diabetic ulcers and minor injuries. This innovative system forms a protective, hydrophobic film directly over the wound site, offering advantages such as ease of application, portability, and enhanced therapeutic efficacy. The composition consists of a eutectic mixture of smart polymers ethyl cellulose, chitosan, and Eudragit dissolved in organic solvents such as ethanol and acetic acid, and enriched with bioactive agents including rosemary extract, and allantoin. Ethyl cellulose provides water resistance and mechanical robustness; chitosan contributes biocompatibility, biodegradability, and antimicrobial action; and Eudragit enhances film flexibility and enables controlled drug release. Ethanol acts as a solvent and plasticizer, improving film elasticity and drug permeation, while acetic acid aids in polymer solubilization and modulates structural properties. Allantoin supports tissue regeneration and maintains an optimal moist environment for healing. Collectively, these components create a multifunctional, film-forming wound dressing that not only acts as a barrier against microbial and environmental threats but also promotes accelerated and efficient tissue repair.

**Keywords:** Wound healing, Polymeric Spray, Film Forming, Anti-inflammatory, Allantoin

**PC-158**

**NOSE-TO-BRAIN DELIVERY OF DONEPEZIL HYDROCHLORIDE VIA NANOSTRUCTURED LIPID CARRIERS EMPLOYING A NATURAL PENETRATION ENHANCER**

Renuka Lolage, Parth Pawar, Avinash Tekade
Department of Pharmaceutics, Marathwada Mitra Mandal's College of Pharmacy, Pune-411033 (M.S.), India
lolagerenuka42@gmail.com

Alzheimer's disease is a progressive neurodegenerative disorder where effective therapy is limited due to poor brain uptake of conventional oral drugs. Donepezil hydrochloride, a widely prescribed acetylcholinesterase inhibitor, suffers from low bioavailability and first-pass metabolism. The objective of the present work was to develop intranasal nanostructured lipid carriers (NLCs) of Donepezil HCl using a natural penetration enhancer to achieve direct nose-to-brain delivery. NLCs were prepared by homogenization–ultrasonication and evaluated for particle size, polydispersity index, zeta potential, entrapment efficiency, and drug release. The optimized formulation exhibited a mean particle size of ~110 nm with narrow distribution, entrapment efficiency above 65%, and stability for 90 days at 4 °C. In-vitro and ex-vivo studies demonstrated sustained release and improved permeation across nasal mucosa compared to control. Histopathological examination confirmed the absence of mucosal toxicity. Thus, intranasal NLCs of Donepezil HCl incorporating a natural penetration enhancer present a promising non-invasive strategy to enhance brain targeting and improve therapeutic outcomes in Alzheimer's disease management.

**Keywords:** Donepezil HCl, Nanostructured lipid carriers, Nose-to-brain delivery, Natural penetration enhancer, Alzheimer's disease.

**DEVELOPMENT AND EVALUATION OF FLUVASTATIN NANOCRYSTALS FOR ENHANCED SOLUBILITY AND BIOAVAILABILITY OF BCS CLASS II LIPID-LOWERING DRUGS**

Sudeep M S
Department of Pharmaceutical Sciences, Ikon Pharmacy College, Bidadi, Ramanagara (T&D), Karnataka, India
sudeep.ms.9611@gmail.com

Poor aqueous solubility is a major limitation in the development of BCS Class II drugs, including Fluvastatin, leading to reduced bioavailability and therapeutic efficacy. The present study aimed to develop and evaluate nanocrystals of Fluvastatin using the antisolvent precipitation method to enhance solubility, dissolution rate, and bioavailability. The objectives were to prepare Fluvastatin nanocrystals, optimize the formulation with different stabilizers, and evaluate their physicochemical characteristics such as particle size, zeta potential, crystallinity, and dissolution profile, along with stability assessment. Nanocrystals were successfully prepared and characterized using techniques including Scanning Electron Microscopy (SEM), X-Ray Diffraction (XRD), Differential Scanning Calorimetry (DSC), and Fourier Transform Infrared Spectroscopy (FTIR). The results demonstrated a significant reduction in particle size and improved surface properties compared to the pure drug. In vitro dissolution studies showed enhanced dissolution rates, while stability studies confirmed the

ISBN: 978-81-980623-8-3

formulations remained stable over time with no major changes in particle size or zeta potential. The findings indicate that nanocrystal formulation markedly improved the solubility and dissolution behavior of Fluvastatin, thereby enhancing its bioavailability potential. In conclusion, nanocrystals represent a promising and efficient approach for overcoming solubility-related challenges of BCS Class II drugs, offering an effective strategy for the formulation of lipid-lowering agents such as Fluvastatin.

**Keywords:** Fluvastatin, Nanocrystals, Antisolvent precipitation, BCS Class II drugs, Solubility enhancement, Bioavailability, Dissolution rate, Stabilizers, Particle size reduction, Lipid-lowering drug.

**DESIGN DEVELOPMENT AND OPTIMIZATION OF ORAL THIN FILM FOR TREATMENT OF CARDIOVASCULAR COMPLICATIONS: A QBD APPROACH**

Yogita Thakur1,2, Mohammad Adnan Raza1,2, Ajazuddin1,2
Rungta College of Pharmaceutical Science and Research, Kohka, Kurud Road, Bhilai, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023
yogitat087@gmail.com

The present study focuses on the design, development, and optimization of orally thin films (OTFs) of Azelnidipine, aimed at enhancing patient compliance and ensuring rapid onset of action through buccal drug delivery. A Box-Behnken design was employed to systematically evaluate the effects of three critical formulation variables: hydroxypropyl methylcellulose E15 (HPMC E15) as the film-forming polymer, polyethylene glycol 300 (PEG 300) as the plasticizer, and sodium starch glycolate as the super disintegrant. These factors were analysed at three levels to determine their influence on two key response variables—disintegration time and percentage drug dissolution. Twelve experimental formulations were prepared and assessed, revealing disintegration times ranging from 15 to 25 seconds and dissolution percentages indicative of efficient drug release. Statistical analysis demonstrated that higher concentrations of HPMC E15 tended to prolong disintegration time due to increased matrix density, whereas the inclusion of sodium starch glycolate significantly reduced disintegration time by enhancing film disintegration through rapid swelling and wicking. PEG 300 was found to support film flexibility and had a moderate impact on disintegration and drug release. Response surface methodology and predictive modelling facilitated the identification of an optimized formulation with desirable characteristics: rapid disintegration and high dissolution efficiency. This study highlights the effectiveness of using a Box-Behnken design for the development of OTFs, offering a promising approach for the delivery of Azelnidipine in a patient-friendly dosage form.

**FORMULATION AND EVALUATION OF DIPHENHYDRAMINE HYDROCHLORIDE MULTIPLE EMULSIONS**

Deekshitha Ramani V, Ruthi Remlalmuanpuii, Csreddy Bonepally*
Sarojini Naidu Vanita Pharmacy Mahavidyalaya
bcsrhnk@gmail.com

The objective of this study was to formulate and evaluate a multiple emulsion system (w/o/w) containing diphenhydramine hydrochloride, an antihistamine widely used for the treatment of allergic reactions and motion sickness. Multiple emulsions offer a novel approach for sustained drug delivery and improved drug stability, making them suitable for topical or oral applications. In this study, a water-in-oil-in-water (w/o/w) emulsion was prepared using a two-step emulsification process. Span 80 was used as the lipophilic emulsifier for the primary w/o emulsion, while Tween 80 served as the hydrophilic emulsifier for the secondary w/o/w emulsion. The prepared emulsions were evaluated for stability, globule size, viscosity, zeta potential, pH, drug content, and in vitro drug release profile. The formulation exhibited acceptable physical stability over a period of 30 days with minimal phase separation and consistent droplet size distribution. In vitro release studies indicated a sustained release of diphenhydramine hydrochloride from the multiple emulsion system compared to conventional formulations. The results suggest that multiple emulsions can be a promising carrier system for the controlled delivery of diphenhydramine hydrochloride, potentially enhancing patient compliance and therapeutic efficacy.

**Keywords:** Diphenhydramine hydrochloride, multiple emulsion, sustained release, w/o/w emulsion, drug delivery, emulsifier

**PREPARATION AND EVALUATION OF CURCUMIN FILM-FORMING GEL**

Sandeep A, Dr.Sowjanya Battu, Dr.B A Vishwanath
Department Of Pharmaceutics, Aditya Bangalore Institute Of Pharmacy Education And Research, Bengaluru, India-560064.
sandeepanandakumark@gmail.com

Skin is considered one of the effective routes for drug administration, suitable for both local and systemic delivery. Its effectiveness depends on the physicochemical properties of the drug and the ability of the formulation to adhere during therapy, thereby promoting drug penetration through the skin. Curcumin is an anti-inflammatory agent, here we formulate curcumin into a gel that forms a film when applied to the skin. This gel is developed for the treatment of inflammatory conditions such as rheumatoid arthritis, where the drug needs to be applied and maintained at the site of treatment for effective therapy. Topical film-forming formulations represent an emerging class of drug delivery systems. When applied topically, these formulations adhere to the skin surface, forming a thin transparent film that enables controlled delivery of the active ingredient to the underlying tissue. An additional advantage of this gel system is its transparency, which enhances patient acceptance. In this discussion, film-forming gel systems are described as a promising approach for topical drug delivery.

**Keywords:** Curcumin, film-forming gel, topical drug delivery, transdermal system, anti-inflammatory, rheumatoid arthritis.

**DEVELOPMENT OF NUTRITIONAL PEANUT OIL SUBMICRON-OLEOGEL ICE CREAM**

Monoranjan Sahu*, Prakash Kumar Palai, Subhashree Sahoo
Department of Pharmaceutics, Kanak Manjari Institute of Pharmaceutical Sciences, Rourkela, Odisha
monoranjansahu02@gmail.com

This research explored the use of submicron-oleogel which was comprised of peanut oil and bees wax instead of solid fat in ice cream preparation. Oleogel is considered as a novel candidate to replace animal fat with vegetable oil, being a research hotspot in the field of saturated fat substitution. By comparing oleogel ice cream to two ice creams (peanut oil ice cream and butter ice cream), the results showed that the overrun rate of oleogel ice cream was higher than peanut oil ice cream, and the melting rate was lower than that of butter ice cream. Besides, the hardness of peanut ice cream was moderate, and the first dropping time of oleogel ice cream was no significant difference with the butter ice creams, whereas longer than that of peanut oil ice cream. The heating (at 90 °C) times of 2 h, 4 h and 6 h were selected to prepare the oleogels. A particle size of approximately 150 nm and zeta-potential of around −26 mV were achieved along with a high drug entrapment efficiency. Among the four heating times, oleogels prepared by heating for 6 h showed the best storage stability, ionic strength stability and shear resistance. Both the viscosity and fat globule stability of the oleogel ice cream was the highest. This research expanded the application of oleogels in the ice cream industry and provided a reference for the development of more nutritional ice cream products suitable for the long-term consumption by sub-healthy people.

**Keywords:** Peanut oil; Submicron-oleogel; Ice cream; Saturated fat; Sub-healthy people.

Green nanotechnology offers a sustainable and eco-friendly approach for nanoparticle synthesis. In the present study, silver nanoparticles

ISBN: 978-81-980623-8-3

(AgNPs) were fabricated using an aqueous extract of Triticum aestivum (wheatgrass) and their anticancer potential were explored. Several reaction parameters including silver nitrate concentration, temperature, pH, extract-to-$AgNO_3$ ratio, and incubation time were optimized to obtain stable nanoparticles of smaller size. The optimal synthesis was achieved at 80 °C, pH 9, 1 mM $AgNO_3$, with a 1:1 extract-to-AgNO3 ratio and a 24 hr reaction period. Formation of the Triticum aestivum-AgNPs (TA-AgNPs) was confirmed by the color transition from pale to dark reddish-brown and the characteristic surface plasmon resonance peak at 412 nm in UV–Vis spectra. FTIR analysis indicated that phytochemicals present in the extract were involved in reduction and stabilization processes. TEM images showed predominantly spherical particles with diameters in the 15-30 nm range, while zeta potential measurements (–14.7 mV) confirmed colloidal stability. EDX spectra further verified the presence of silver, accounting for 40.15% by weight. The synthesized nanoparticles exhibited significant antioxidant activity and were biocompatible. The anticancer potential of TA-AgNPs were tested against ovarian (PA-1), prostate (DU-145), lung (A549), and breast (MCF-7) cancer cell lines using the MTT assay, with the strongest growth-inhibitory effect observed in ovarian cancer cells, as reflected by $IC_{50}$ values. These findings suggest that T. aestivum-derived AgNPs hold promise as a potential therapeutic agent, particularly for the treatment of ovarian cancer.

**Keywords:** Triticum aestivum, silver nanoparticles, anti-cancer, green nanotechnology

## DEVELOPMENT AND EVALUATION OF A PLANT BASED ORAL FORMULATION FOR URINARY TRACT INFECTION MANAGEMENT

Yash Lokhande, Amey Dongaonkar, Nishant Awandekar, Milind Umekar
Department of Industrial Pharmacy, Smt. Kishoritai College of Pharmacy, Kamptee Dist. Nagpur 441002
yash24122000@gmail.com

Urinary tract infections (UTIs) are among the most common infectious diseases worldwide with increasing resistance of causative pathogens to conventional treatments limiting the effectiveness of existing therapies. This study aimed to explore an alternative treatment approach by evaluating the antimicrobial potential of plant-derived extracts and developing a suitable oral dosage form for UTI management. Corn silk extract was selected for its known antimicrobial properties. The extracts were subjected to phytochemical screening which revealed the presence of bioactive compounds such as flavonoids, phenolic compounds, tannins, and alkaloids. In vitro antibacterial studies demonstrated significant inhibitory activity of the extract against major UTI-causing pathogens, including Escherichia coli, Staphylococcus aureus, and Klebsiella pneumoniae, confirming its therapeutic promise. Preformulation studies established the solubility, stability, and compatibility of the extract with other excipients, ensuring feasibility for oral formulation. An optimized oral dosage form was then developed using a $3^3$ full factorial design, with the optimized batch showing a disintegration time of 34 seconds and drug release of 75.06% within 60 minutes. Post-formulation evaluation confirmed desirable characteristics, including appropriate disintegration time, satisfactory release profile, and compliance with standard quality parameters. Overall, the findings suggest that the plant extract possesses strong antibacterial potential, warranting further in vivo studies and clinical evaluation to establish its role as a novel therapeutic option for the effective management of urinary tract infections.

**Keywords:** Urinary tract infections, Corn silk extract, Oral dosage form, Phytochemical screening.

## FORMULATION DEVELOPMENT, CHARACTERIZATION AND COMPARATIVE EVALUATION OF A NOVEL ECOFRIENDLY TOOTHPASTE

Prasanth Kumar M*,
Department of Pharmaceutics, Bhagwant University, Ajmer, Rajasthan, India.

Toothpaste has significant role in maintaining the oral hygiene and health of teeth. The medicated toothpastes used for managing tooth problems and preventing tooth decay find a huge market potential as, 5 out of 10 Indians have these issues with their teeth. But, some of the widely used toothpastes are reported to have heavy metal content which adversely affects health and acceptance among users. Also, the manufacturing and disposal of those toothpastes cause long-lasting impact on environmental issues such as enhanced carbon foot print, Threat to marine life. In this context the herbal based, repurposed, ecofriendly toothpaste still remains less explored in India. In this work a Novel Toothpaste (NT) enriched with Punica granatum. L, Murraya koenigii, Moringa oleifera were developed as sustainable and economical product. The prepared toothpaste was characterized for different pharmaceutical parameters such as pH, extrudability, viscosity, spreadability, foamability, cleaning action and stability. The NT had characteristic green color, and acceptable appearance. Unadjusted PH of the paste was around 8.5 showed no extra buffering agents in the final formulation. Additionally, the NT was found to have sufficient foamability and foamability with small quantity of water making it ideal choice for comfortable brushing. The viscosity of the NT was 10,000 Poise. The cleaning action was slightly high for Novel Toothpaste. All the comparative evaluation showed satisfactory results with selected marketed toothpastes. The invitro antimicrobial activities with Staphylococcus aureus, Escherichia coli and Pseudomonas aeruginosa were performed to prove the effectiveness in managing oral health. A Short-term stability study of the finished NT was also performed, which exhibited physicochemical and microbiological stability of the toothpaste. In conclusion, a Novel Toothpaste having similar pharmaceutical characteristics compared to marketed toothpastes were prepared with new indigenous herbal and non-synthetic ingredients. The stability study, Physicochemical evaluation and invitro antibacterial activities proved that a novel, stable, sustainable toothpaste can be developed as an alternative to synthetic toothpaste in a ecofriendly approach.

**Keywords:** Novel Toothpaste, Dental Caries, Gingivitis, Punica granatum

## PHARMACOKINETIC EVALUATION OF SOLID DISPERSION FORMULATIONS OF ATORVASTATIN AND ROSUVASTATIN WITH BIOENHANCERS BERBERINE AND QUERCETIN

Gausiya Sheikh and Minakshi Rajgire
Department of Pharmaceutical Quality Assurance, Anurag College of Pharmacy, Warthi, Bhandara, India-441909
gausiyaasheikh9@gmail.com

In the present study, in-vivo pharmacokinetic evaluation of solid dispersion (SD) formulations of atorvastatin (ATV) and rosuvastatin (RSV) was conducted using bioenhancers berberine (BER) and quercetin (QUR). The objective was to assess the effect of bioenhancers on the oral bioavailability of ATV and RSV when administered to Sprague Dawley rats. A validated HPLC method was developed for the quantification of ATV and RSV in plasma, employing a mobile phase of acetonitrile, 0.1% formic acid solution, and methanol (45:35:20 v/v) with detection at 247 nm. The method showed excellent linearity ($R^2$ = 0.998), precision (RSD < 1%), and accuracy (>99%). The in-vivo results demonstrated that solid dispersions significantly enhanced pharmacokinetic parameters compared to pure drug and physical mixtures. For ATV, the Cmax increased from 564.77 ± 120.65 ng/mL (control) to 1641.18 ± 155.41 ng/mL (SDc-ABK-3 with BER) and 1291 ± 166 ng/mL (SDc-AQK-3 with QUR), while $AUC_{0-\infty}$ improved from 3444.12 ± 331.84 to 18669.43 ± 3060.66 ng·h/mL. Similarly, RSV Cmax increased from 532.87 ± 118.56 to 1539.17 ± 151.35 ng/mL with BER and to 1219 ± 167 ng/mL with QUR. The $AUC_{0-\infty}$ values followed the same trend. This enhancement was attributed to improved solubility and absorption due to the presence of bioenhancers. Thus, the study concludes that the incorporation of BER and QUR in solid dispersions significantly improves the oral bioavailability of ATV and RSV.

## FORMULATION AND EVALUATION OF SACCHAROMYCES BOULARDII-LOADED COSMETIC STICK FROM VITIS VINIFERA L. FOR SKIN ENHANCEMENT

Ms Saranya K G and Nishana K S
Department of Pharmaceutics, Nirmala College of Health Science, Chalakudy, Thrissur- 680311
saranyakg89@gmail.com

ISBN: 978-81-980623-8-3

The integration of probiotics in cosmetics represents a growing trend toward natural, microbiome-balancing products that offer anti-aging, anti-inflammatory, and hydrating benefits. This study aimed to isolate Saccharomyces boulardii from Vitis vinifera L. (grapes) and formulate a probiotic-loaded cosmetic stick for skin enhancement, evaluating its physicochemical and antioxidant properties. S. boulardii was isolated using Sabouraud dextrose agar and identified through morphological (whitish cream color, spherical shape, fruity odor), staining (positive yeast viability and lactophenol cotton blue), and biochemical tests (positive flocculation, H2S, starch hydrolysis; negative killer toxin). Six formulations (CS1-CS6) were prepared via fusion method, incorporating beeswax, carnauba wax, lanolin, isopropyl myristate, emulsifying wax, propylene glycol, glycerol, salicylic acid, lavender oil, vitamin E, phenoxyethanol, and distilled water. Evaluations included physical appearance, homogeneity, surface anomalies, aging stability, hydration (skin test and corneometer), melting point (59-64°C), breaking point (140-160g), pH (4-6), spreadability (excellent for CS5 and CS6), hardness (5-10N), and antioxidant activity via DPPH assay. CS5 emerged as optimal, exhibiting smooth pale yellow texture, excellent hydration, melting point 62±0.04°C, breaking point 160±0.09g, pH 5.12±0.012, spreadability 4.5±0.5 gcm/s, hardness 6±0.05N, and 65.875% radical scavenging activity. This probiotic-infused stick demonstrates promising potential for sustainable, effective skincare, balancing efficacy with user-friendly application and stability, paving the way for innovative microbial-based cosmetics.

**Keywords:** S.boulradii, probiotics, cosmetic stick, Corneometer

## FORMULATION AND EVALUATION OF ORAL DISPERSIBLE TABLETS OF FELODIPINE

Sonali P Kale*, R B Pandhare, A R Pawar, V. K. Deshmukh
Mula Education Society's College of Pharmacy, Sonai, Tal-Newasa, Dist-Ahilyanagar, Affiliated to Savitribai Phule Pune University, Maharashtra-414105
kalesonali1112@gmail.com

The present study aimed to develop and optimize Felodipine Orodispersible tablets (ODTs) using various concentrations of superdisintegrants to enhance dissolution rate and improve patient compliance. A 32 full factorial design was employed to study the influence of crosscarmellose sodium (4–8% w/w) and microcrystalline cellulose (20–40% w/w) on disintegration time and in-vitro drug release. Preformulation studies, including organoleptic evaluation, solubility determination, melting point analysis, FTIR and DSC confirmed the purity of the drug and its compatibility with excipients. The prepared powder blends showed excellent micromeritic properties, enabling direct compression. All formulations met pharmacopeial requirements, exhibiting uniform weight, adequate hardness, low friability (<1%) and rapid disintegration. The optimized batch (F5) disintegrated in 24.3 seconds and achieved 99.5% drug release within 15 minutes. Stability studies conducted for six months under ICH-recommended conditions indicated no significant changes in physical appearance, drug content or dissolution profile. These findings suggest that the optimized ODT formulation can serve as a stable, patient-friendly dosage form with potential for enhanced antihypertensive therapy.

**Keywords:** Felodipine, Orodispersible Tablets, Superdisintegrants, Stability Studies.

**PC-170**

## PHARMACEUTICAL DEVELOPMENT AND EVALUATION OF NOVEL ORODISPERSIBLE BUCCAL STRIPS OF CARBAMAZEPINE FOR RAPID DRUG DELIVERY AND ENHANCED BIOAVAILABILITY

Sakshi Bhanap and Laxmi Kanna,Rajashree Kulkarni
Department of Pharmaceutics, Punyashlok Ahilyadevi Holkar Solapur University Solapur,Maharashtra,India – 413 255
Sakshi.bhanap@gmail.com

This study focuses on the development of novel orodispersible buccal strips of carbamazepine (CBZ) aimed at achieving rapid drug delivery, enhanced bioavailability, and improved patient compliance, particularly for individuals with dysphagia or difficulty swallowing conventional dosage forms. An accelerated solvent casting method was optimized to prepare thin, flexible, and rapidly disintegrating films. Hydroxypropyl methylcellulose (HPMC E15) and polyvinyl alcohol (PVA) were selected as the primary film-forming agents, PEG-400 served as a plasticizer, citric acid functioned as a saliva-stimulating agent, and crospovidone was incorporated as a superdisintegrant. The drug–polymer mixture was cast onto a flat surface and dried under controlled conditions in a hot-air oven at an elevated temperature to achieve uniform film formation. The prepared strips were evaluated for physicomechanical and quality attributes, including thickness, folding endurance, surface pH, drug content uniformity, disintegration time, and in-vitro drug release. The optimized formulation demonstrated rapid disintegration, satisfactory mechanical strength, uniform drug distribution, and favourable release characteristics, indicating suitability for immediate buccal absorption. The accelerated solvent casting method offered reduced processing time, consistent reproducibility, and produced stable dosage forms with desirable performance attributes. Overall, the developed orodispersible buccal strips of carbamazepine (CBZ) present a promising platform for rapid-onset buccal drug delivery, potentially improving therapeutic outcomes and patient adherence. This formulation approach can be further extended to other drugs requiring quick onset and improved bioavailability, offering broad applicability in modern pharmaceutical development.

**Keywords:** Carbamazepine, Orodispersible, Bioavailability, Hot air ove, Plasticizer

## INVESTIGATION OF A NATURAL BIOENHANCER BASED IN SITU GEL FOR IMPROVING DRUG PERMEABILITY IN THE TREATMENT OF NEUROLOGICAL DISORDER

MAITHILI RAJU FULZELE
Smt. Kishoritai Bhoyar College Of Pharmacy Kamptee
mfulzele05@gmail.com

Neurological disorders often require therapeutic agents to effectively cross biological barriers such as the nasal mucosa or the blood brain barrier to achieve their intended pharmacological effects. This study aimed to evaluate the potential of a natural bioenhancer by formulating a nasal in-situ gel to improve drug delivery to the central nervous system (CNS). An antidepressant neuroactive drug with limited aqueous solubility, was selected for the study. Pre-formulation studies, including organoleptic studies, solubility profile, UV spectroscopy, melting point and FTIR were performed. A statistical Box-Behnken Design was employed to optimize three key formulation variables: polymer concentration, mucoadhesive agent concentration, and natural bioenhancer concentration. The optimized formulations were evaluated for gelation temperature (28.63°C), Strong mucoadhesive strength (3895.34 dyne/cm2), drug content and ex-vivo permeation (95.68%) over 12 hours. The behavioral tests are also performed such as forced swim test, sucrose preference test, open field test and body weight observation test. Results demonstrated that natural bioenhancer significantly enhanced antidepressant drug permeation across the nasal mucosa and was observed consistently in formulations containing higher concentrations of thereby reinforcing its role as a natural bioenhancer. The current study aimed intranasal antidepressant gel formulations with and without natural bioenhancer for antidepressant and anxiolytic activity in a Chronic Mild Stress (CMS) rat model of depression. These findings highlight potential as a natural, safe, and effective bioenhancer for improving the nasal delivery and CNS permeability of neurotherapeutic agents.

**Keywords:** Neurological disorders, Blood brain barrier, Natural bioenhancer, Antidepressant, Nasal in-situ gel.

**PC-172**

## FABRICATION, CHARACTERIZATION OF TAMOXIFEN CITRATE-LOADED CARBON NANOTUBES IN MANAGEMENT OF CANCER

Himanshu Shekhar, Vidya B and H V Gangadharappa*
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, KA, India.
himanshushekhar0512@gmail.com

Breast cancer remains the most common malignancy among women worldwide, highlighting the urgent need for therapeutic approaches that enhance efficacy while reducing systemic toxicity. Nanotechnology-based targeted drug delivery systems hold significant potential in this regard. In the present study, tamoxifen citrate, a selective estrogen

ISBN: 978-81-980623-8-3

receptor modulator, was successfully incorporated into carboxylated multiwalled carbon nanotubes (c-MWCNTs) using sonication and centrifugation techniques. To achieve tumor-specific delivery, biotin and chitosan ligands were conjugated, leading to the formulation Bio-Chi/TAM/e-MWCNT. Physicochemical compatibility of tamoxifen and ligands with c-MWCNTs was confirmed by Fourier Transform Infrared Spectroscopy (FT-IR) and Differential Scanning Calorimetry (DSC), which indicated absence of degradation. Solubility studies identified ethanol as the most suitable solvent, consistent with tamoxifen's Biopharmaceutics Classification System (BCS) class II profile. The nanocarrier exhibited high encapsulation efficiency (80%), demonstrating excellent drug loading capacity. Scanning Electron Microscopy (SEM) revealed preserved nanotubular morphology with uniform chitosan coating, while X-ray Diffraction (XRD) confirmed the amorphous state of the formulation, favorable for enhanced dissolution and bioavailability. In vitro release studies demonstrated pH-dependent drug release, with approximately 90% at acidic pH 4.0 and 40–45% at physiological pH 7.4, suggesting preferential release in the tumor microenvironment. These findings highlight the successful synthesis and characterization of Bio-Chi/TAM/e-MWCNT as a promising targeted nanocarrier for breast cancer therapy. Further studies on biodistribution, therapeutic efficacy, and clearance are needed to advance clinical translation.

## DEVELOPMENT AND EVALUATION OF INTRANASAL LACTOFERRINBASED DULOXETINE IN SITU NASAL GEL FOR TARGETING THE BRAIN

Isha Kalbhor, Vishal Tayade, Satish Polshettiwar
School of Health Sciences and Technology, Dr. Vishwanath Karad MIT World Peace University, Pune

The study was designed to achieve efficient nose-to-brain delivery of the drug while avoiding first-pass metabolism. Lactoferrin, a member of the transferrin family and an iron-binding glycoprotein with attached carbohydrate chains, was selected as the targeting ligand due to its established role in enhancing drug bioavailability and minimizing drug loss. Duloxetine was initially identified and characterized using melting point determination and FTIR analysis. Drug–excipient interactions were further assessed through FTIR and DSC techniques. Preliminary batches of in situ gel were then formulated to optimize polymer concentrations for the desired gelation temperature. Various concentrations of Poloxamer 407 (14, 16, and 18%) and HPMCK4M (0.02 and 0.04%) were tested in the initial batches, and their gelation temperatures were evaluated. Based on these findings, a $3^2$ factorial design was implemented to prepare nine formulations containing 15–18% Poloxamer 407 and 0.01–0.04% HPMCK4M. These formulations were assessed for visual appearance and clarity, pH, gelation temperature (Tsol-gel), drug content, viscosity, mucoadhesive strength, in vitro diffusion, ex vivo permeation, statistical analysis, and accelerated stability. The developed in situ gels were found to be clear and transparent, with pH values within the acceptable range. Drug content across all formulations ranged from 68.09% to 96.14%, indicating satisfactory loading. Gelation temperature varied with polymer concentration, with all formulations falling within the required range of 29–80 °C. Among them, formulation F3 exhibited the most desirable gelation temperature.

**Keywords:** Nose-to-brain delivery, Lactoferrin-targeted in situ gel, Duloxetine, Poloxamer 407

**PC-174**

## SURFACE MODIFICATION OF QUERCETIN NLCS FOR IMPROVED INTRA-NASAL DRUG DELIVERY

Rajath N Raju, Balabhadra Phani VSSK Bhaskar Vinay and Asha Spandana KM*
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, KA, India.
rajath.1301@gmail.com

Glioblastoma multiforme (GBM), an extremely aggressive brain tumor, poses substantial treatment challenges due to its invasive nature and restricted drug delivery across the blood–brain barrier. In this study, chitosan surface-modified nanostructured lipid carriers (NLCs) were investigated as a potential therapeutic strategy for managing brain tumors. Preformulation studies, including FTIR, DSC, and XRD, confirmed the compatibility between the drug and excipients. The NLCs were prepared using hot melt homogenization followed by probe sonication, and formulation optimization was performed using a Box–Behnken design with three factors and two responses. Characterization studies, such as FTIR, DSC, XRD, and TEM, demonstrated the formation of stable NLCs with a particle size of 193.4 nm and a zeta potential of 18.9 mV. The entrapment efficiency (%EE) of the final quercetin-loaded NLCs was 81.11 ± 1.14%. In vitro drug release studies at pH 6.8 showed an initial burst followed by sustained release, reaching 85.66%, with the release kinetics fitting the Higuchi model. Pharmacokinetic studies revealed that the optimized NLCs achieved the highest quercetin concentration in the brain, with brain plasma levels 2.6-fold higher than oral solutions and 2.4-fold higher than intranasal solutions. Stability studies indicated that the quercetin-loaded chitosan NLCs remained stable for three months at 4°C and 25°C/60% RH, with no significant change in particle size, while higher temperature conditions (40°C/75% RH) were also evaluated. Overall, these findings suggest that quercetin-loaded NLCs with chitosan surface modification have significant potential as a targeted therapeutic approach for brain tumor treatment.

## FORMULATION AND USE OF NANOEMULSION TARGETING ALCOHOLIC FATTY LIVER DISEASE BY RESPONSE SURFACE METHODOLOGY.

Vishal CS and Hindustan Abdul Ahad
R R College of Pharmacy, Chikkabanavara, R R Layout, Bengaluru, Karnataka, India-566090
amarphulo@gmail.com

The research focused on examining enhanced bioavailability and in vitro dissolution properties of Metadoxine Nanoemulsion and understanding its Characterisation and optimisation. Nine formulations of nanoemulsions formulated by spontaneous emulsification technique, incorporating Tween 20 and olive oil with metadoxine. Central composite design was employed using Design-Expert software to determine and assess the influence of independent variables (Conc of Olive oil and Conc of Tween 20) and dependent variables (Particle Size, Zeta potential and Polydispersity index). The nanoemulsions underwent compatibility studies and various physical evaluations, including analysis of metadoxine content and its morphological analysis. The study observed that the Particle size of the nanoemulsion decreased as the levels of Tween 20 increased in the formulation. Particle Size of optimised formulation F8 was 275.7 nm, the zeta potential measurement was -30.6 Mv, followed by drug content showing around 88 % .In vitro dissolution studies revealed that the lower particle size exhibited an enhanced dissolution rate at 8 hours, 89.93 ± 3.319 %, compared to the pure drug 24.38 ±3.31 % and had better stability studies. The initial organic phase of the emulsion optimisation is crucial for the nanoemulsion and its physicochemical properties of the nanoemulsion. The findings underscore the nanoemulsion droplets incorporating metadoxine using olive oil with tween 20, which enhances bioavailability, thus this approach can be effective strategy, this approach proves to be an effective strategy for delivering drugs.

**Keywords:** Metadoxine, Nanoemulsion, Design, Bioavailability and Dissolution.

## DEVELOPMENT AND CHARACTERIZATION OF ECO-FRIENDLY FACE MASKS FROM COCONUT FIBRE FOR SUSTAINABLE PERSONAL PROTECTION

Raveesha Peeriga1*
1V. V. Institute of Pharmaceutical Sciences, Seshadri Rao Knowledge Village, Gudlavalleru-521356, Krishna District, Andhra Pradesh, India.
drprsha@gmail.com

The COVID-19 pandemic has heightened global demand for sustainable, low-cost, and biodegradable protective face masks. This study investigates the potential of coconut fibre (Cocos nucifera L.) as a primary material in mask fabrication due to its abundance, tensile strength, and inherent antimicrobial properties. Coconut fibres were processed through alkali treatment, sterilization, and mechanical refinement to achieve a fine, breathable nonwoven structure. Physical

ISBN: 978-81-980623-8-3

characterization, including fibre diameter distribution, porosity, air permeability, and tensile strength, demonstrated that optimized fibre mats exhibit comparable filtration efficiency to commercial masks while maintaining superior biodegradability. Fourier-transform infrared spectroscopy (FTIR) and scanning electron microscopy (SEM) analyses confirmed fibre surface modification, enhancing bonding and uniformity within the mask layers. Filtration performance was assessed against aerosols in the submicron range, showing an efficiency exceeding 85% at optimal fibre packing density. Moreover, water contact angle measurements indicated hydrophobic behaviour, further improving user comfort. These findings highlight coconut fibre as a promising renewable material for eco-friendly personal protective equipment, reducing environmental pollution from synthetic mask waste. This work supports the integration of agricultural by-products in medical and consumer protective technologies, fostering circular economy approaches in health care and environmental sustainability.

**Keywords:** Ecofriendly, sustainable, Cocos nucifera, Palmae

**FAST-DISSOLVING ORAL BREXPIPRAZOLE FILMS: A NOVEL STRATEGY FOR ENHANCED DISSOLUTION AND PATIENT ADHERENCE**

Joeann Marylin Wilson*, Yugal Bhattarai, Preethi Sudheer, Dezney Remica Fernandes
*Department of Pharmacy Practice, Krupanidhi College of Pharmacy, Bengaluru, Karnataka, India -560035
joeannmw@gmail.com

Atypical antipsychotic brexpiprazole is a BCS Class II drug indicated for schizophrenia and major depressive disorder, yet its clinical utility is limited by poor patient compliance and low aqueous solubility. This study developed fast-dissolving oral films (FDOFs) of brexpiprazole via solid dispersion to enhance solubility, dissolution rate, and patient adherence. Solid dispersions were formulated using carriers such as Mannitol, HPMC, and HPMC β-cyclodextrin at drug-to-carrier ratios of 1:1, 1:2 and 1:5, utilising solvent evaporation and freeze-drying techniques. The freeze-dried formulation 1:2 ratio demonstrated optimal performance and was selected for spray-drying comparative analysis. This optimised dispersion was embedded into FDOFs containing PVA (film-forming agent), glycerin (plasticiser), poloxamer (wetting agent), citric acid (saliva stimulant) and sweeteners. Films were characterised for drug content, physical attributes, solubility, disintegration time, and in vitro drug release profiles. The optimised freeze-dried dispersion showed a 100-fold solubility increase in distilled water and a 25-fold increase in phosphate buffer (pH 6.8). Prepared films disintegrated within 60 seconds, releasing 40.12% of the drug at 10 min and 79.47% at 120 min. XRD and DSC analyses indicated enhanced drug solubility due to peak intensity reduction and lower DSC endotherm heat consumption. These results suggest that FDOFs incorporating solid dispersion can enhance brexpiprazole bioavailability and patient compliance.

**Keywords:** Brexpiprazole, oral disintegrating films, solubility, bioavailability.

**REVOLUTIONIZING SKINCARE WITH NANOCARRIER-ENHANCED RETINOIDS: CONTROLLED RELEASE, REDUCED IRRITATION, AND ACCELERATED RENEWAL**

Sagrika Kawale and Anshuman Borkar
Anurag College of Pharmacy, Warthi, Bhandara, Maharashtra, India-441905
sagrikakawale7777@gmail.com

Our skin often bears the brunt of contemporary living. The impact of stress, late nights, extended screen time, and more intense sunlight as a result of a thinner ozone layer are all harmful. They synergize to accelerate aging. The complexion looks dull and tired as collagen breaks down faster, fine lines and wrinkles appear earlier, and skin renewal is slower. Restoring natural glow and sustaining the sense of strength and richness of the skin are the simple but most important goals of skin rejuvenation. Retinoids are now among the most effective skincare products. It is well known that the vitamin A derivatives make the skin's structure stronger and stimulate collagen production. They fight free radicals, enhance cell growth, and reduce sun damage. As a result, retinoids improve elasticity, smooth out coloring, and fine lines. The issue with conventional retinoids, is they can be irritating to the skin. Scientists have designed delivery systems like hydrogels, solid lipid nanoparticles (SLNs), liposomes, and nano-emulgels to bypass this. The skin may be treated with retinoids less painfully due to these carriers, which also enhance stability, improve absorption, and reduce side effects. Even more recently, advanced formulations utilize lipid nanocarriers to fuse retinol and peptides together. This combination of conventional treatment is superior in terms of controlled release, better tolerance, and faster repair of skin. These innovative delivery systems are changing the skincare industry as innovation remains on the rise. They promise non-surgical, effective revitalization, getting us closer to radiant, healthy-looking skin that feels renewed.

**Keywords:** Retinoid, Skin rejuvenation, Anti-aging, Nano carrier, Collagen stimulation.

**PC-179**

**COMPARATIVE OF EXCIPIENTS OF HERBAL ORIGIN OVER SYNTHETIC**

Ram S Rathod
MGV's Pharmacy College Nashik Panchavati Maharashtra
rsrmgv1510@gmail.com

Excipients play a pivotal role in the formulation of pharmaceutical dosage forms by imparting desirable physicochemical and biopharmaceutical properties, thereby ensuring product stability, safety, and patient acceptability. Traditionally, synthetic and semi-synthetic excipients such as polyvinylpyrrolidone (PVP), polyethylene glycol (PEG), hydroxypropyl methylcellulose (HPMC), and sodium starch glycolate have dominated the pharmaceutical industry due to their reproducibility, high stability, and well-established regulatory acceptance. These excipients are manufactured under controlled conditions, which minimizes batch-to-batch variation and assures consistent performance. However, concerns related to their cost, long-term toxicity, limited biodegradability, and environmental sustainability have encouraged the exploration of alternative sources. Herbal excipients, derived from natural plant origins such as gums, mucilages, pectin, starch, and alginates, have gained prominence in recent years. They are biodegradable, biocompatible, widely available, and cost-effective, offering multifunctional roles as binders, disintegrants, stabilizers, and film formers. Furthermore, the growing patient inclination toward natural and “green” formulations enhances their appeal in modern drug delivery systems. Despite these advantages, herbal excipients face challenges including variability in quality due to geographical and seasonal factors, microbial contamination, limited shelf stability, and relatively less pharmacopeial standardization. A comparative evaluation indicates that while synthetic excipients assure reliability and global regulatory acceptance, herbal excipients provide safer and eco-friendly alternatives that align with sustainable pharmaceutical practices. The future of excipient research lies in developing modified or semi-synthetic natural excipients that combine the advantages of both classes, thereby ensuring efficiency, safety, and environmental compatibility in dosage form design.

**PC-180**

**QUALITY BY DESIGN APPROACH FOR DEVELOPMENT AND OPTIMIZATION OF DIACEREIN-LOADED TRANSFEROSOMES CARRIER GEL FOR ENHANCED TRANSDERMAL DELIVERY**

Srinivasa Reddy Cheedipudi and Prasanthi Boddu
Department of Pharmaceutical Sciences, GITAM School of Pharmacy | GITAM (Deemed to be University) Visakhapatnam, Andhra Pradesh, India- 530045
srinivasch269@gmail.com

Diacerein is an anti-inflammatory agent with potential in osteoarthritis treatment; however, its poor aqueous solubility and limited oral bioavailability restrict its therapeutic efficacy. The objective of the present study was to develop and optimize a diacerein-loaded transferosomal gel for enhanced transdermal delivery using a Quality by Design (QbD) approach. Transferosomes were prepared via the thin-film hydration technique using varying concentrations of Span 80 and phosphatidylcholine, followed by statistical optimization through a Box–Behnken experimental design. The optimized formulation was evaluated for particle size, polydispersity index (PDI), entrapment efficiency, and drug content. The selected formulation was incorporated into a gel base and characterized for in vitro drug release and physicochemical

ISBN: 978-81-980623-8-3

properties using DSC, XRD, SEM, and FTIR analyses. Additional evaluations included pH, viscosity, Spreadability, ex vivo skin permeation, and stability studies. The optimized formulation exhibited a vesicle size of 142.6 ± 2.45 nm, PDI of 0.282 ± 0.012, and entrapment efficiency of 95.34 ± 2.18%. Ex vivo skin permeation studies demonstrated a flux of 124.40 µg/cm²/h across albino Wistar rat skin. SEM confirmed spherical vesicle morphology and uniform distribution. Drug release followed the Higuchi model, indicating a sustained release mechanism. These findings suggest that the developed transferosomal gel system offers an effective strategy for the transdermal delivery of diacerein, potentially improving therapeutic outcomes and patient compliance.

**Keywords:** Diacerein, Transferosomes, Box–Behnken experimental design, Transdermal drug delivery.

## FOAM BASED DRESSING SYSTEMS FOR DIABETIC WOUND HEALING

Mitali Gandhi, Rahul Padalkar, Ashwini Madgulkar
Department of Pharmaceutics, All India Shri Shivaji Memorial Society's College of Pharmacy, Pune, Maharashtra, India - 411001.
gandhimitali61@gmail.com

Diabetic wounds are particularly challenging to heal due to multiple pathological factors and frequent infections. The impaired functioning of essential cells such as vascular endothelial cells, fibroblasts, and epithelial cells hinders the repair process in the complex diabetic wound environment. Traditional wound care options often prove insufficient in addressing chronic diabetic wounds, creating a demand for advanced dressing systems that promote faster healing and effective management. This study aimed to develop a foam-based dressing system integrated with a hydrogel containing esmolol hydrochloride and D-panthenol, and to evaluate its potential in diabetic wound management with a focus on maintaining hydration, enhancing healing, and improving infection control. Cytotoxicity of esmolol hydrochloride was assessed by MTT assay, which revealed no cytotoxic effect up to 250 µM concentration. Based on these findings, hydrogel formulations were prepared with esmolol hydrochloride (14%) and D-panthenol (5%) and subsequently incorporated into a foam-based dressing. The prepared system was evaluated for wound healing activity using an excision wound model in streptozotocin-induced diabetic rats over 21 days. The dressing-treated group demonstrated nearly 96% wound closure by day 21. Histopathological evaluation confirmed significant cell proliferation, tissue remodeling, and collagen deposition. Biochemical analysis further showed increased hydroxyproline and hexosamine levels, indicating enhanced collagen formation and extracellular matrix synthesis. Foam-based dressing systems incorporating hydrogel with esmolol hydrochloride and D-panthenol present a promising approach for diabetic wound care by combining effective moisture retention with exudate absorption, thereby accelerating healing and improving overall wound management.

**Keywords:** Diabetic wound healing, Esmolol hydrochloride, D-panthenol, Hydrogel formulation

## FORMULATION AND EVALUATION OF QUETIAPINE SOLID DISPERSION

T. Mahitha, K. Rama Devi
Department Of Pharmaceutical Technology, Raghu College of Pharmacy, Visakhapatnam, Andhra Pradesh, India.
Mahithareddytetali@gmail.com

Quetiapine fumarate is a dibenzothiazepine antipsychotic agent commonly used in the treatment of schizophrenia, bipolar disorder, and major depressive disorder. Its therapeutic effectiveness is limited due to poor aqueous solubility, low oral bioavailability and variable absorption. Solid dispersion technology has been explored as a promising strategy to enhance solubility and dissolution rate of poorly water-soluble drugs. Solid dispersions are prepared by using different weight ratios of carrier and drug using methods like kneading, solvent preparation, microwave irradiation, super critical anti solvent process. The present study was aimed to formulate and evaluate solid dispersions of quetiapine fumarate using different carriers such as soluplus, kolliphor P338, kolliphor P407 were used and also a natural substance , orange peel powder as a carrier. The prepared formulations were evaluated for drug content, solubility, and in-vitro dissolution studies. Additionally, characterization techniques such as Fourier transform infrared spectroscopy (FTIR), Differential scanning calorimetry (DSC) studies. Solid dispersion technology proved to be an effective and to enhance the solubility and bioavailability of quetiapine fumarate, thereby improving its therapeutic potential and patient compliance.

**Keywords:** Quetiapine fumarate, Solid dispersions, Solubility enhancement, Dissolution.

## INFLUENCE OF DIFFERENT MARKETING STRATEGIES OF SUNSCREEN PRODUCTS ON CONSUMERS

Deepthi Mathew, Akash M, Alfiya Shihab
Department of Pharmaceutics, Pushpagiri College of Pharmacy, Tiruvalla, Pathanamthitta, Kerala, India- 689101.
deepthimathew80@gmail.com

In recent years, the global skincare market has grown rapidly due to growing awareness of the negative effects of UV radiation and the significance of sun protection.In particular, sunscreen products are now a necessary part of daily skincare regimens, which has greatly aided in the growth of the market. Researchers and marketers alike continue to be very interested in how well marketing tactics affect consumer purchasing decisions. The various tactics, including pricing, packaging, product endorsements, and advertising, may have different effects on consumers' decisions, including their selection of sunscreen products. The goal of this study is to determine how various marketing tactics affect consumers' decisions to buy skincare products in the Peringara Panchayat, a region with a wide range of age groups and skincare awareness levels. 260 participants, ages 17 to 70, participated in the survey, which looked at how brand recognition, product positioning, promotional offers, and advertising campaigns impact sunscreen consumers' decisions. Analyzing consumer preferences and behavior is another goal of the study.It was found that important elements like advertising campaigns, packaging, and pricing strategies influenced customer preferences and purchase decisions. The results show that eco-friendly and high-quality features are essential for building consumer loyalty, and that young adults especially women respond best to marketing campaigns. It also highlights how important it is to foster sustainability and increase consumer trust in order to foster brand loyalty in a cutthroat industry. These observations offer helpful direction for improving marketing strategies to better meet customer expectations.

**Keywords:** Marketing strategies, Advertisement, Pricing, Packaging.

## FORMULATION, DEVELOPMENT AND EVALUATION OF SPHERICAL AGGLOMERATES OF BEMPEDOIC ACID FOR ENHANCED COMPRESSIBILITY AND DISSOLUTION

Ahir Misha Kishor, Patel Hiranshiben Arunbhai, Sachin B. Narkhede
Smt. B.N.B. Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
mamtaahir600@gmail.com

This research focuses on improving the pharmaceutical properties of Bempedoic Acid, a drug used for the treatment of hyperlipidemia, by addressing its poor water solubility and challenging physical characteristics. Using an innovative technique called quasi-emulsion solvent diffusion, the drug was reformulated into spherical agglomerates with the polymer Eudragit L100. This process significantly improved flowability, compressibility, and dissolution rate—critical factors for efficient tablet production and effective drug release in the body. Through systematic optimization, the ideal polymer concentration and processing conditions were identified, resulting in agglomerates that are not only easier to handle during manufacturing but also release the drug more rapidly and completely compared to the original crystalline form. The resulting tablets exhibited excellent mechanical strength, uniformity, and stability, fulfilling all pharmacopeial standards. Most importantly, the new formulation demonstrated a significantly faster release profile than a leading marketed product, indicating the potential for better patient compliance and therapeutic outcomes. This study successfully demonstrates that spherical agglomeration is a powerful and practical strategy to overcome the limitations of Bempedoic Acid, paving the way for more reliable manufacturing and enhanced therapeutic performance in the management of hyperlipidemia.

**ADVANCEMENTS IN DERMA SERUM: A COMPREHENSIVE REVIEW OF FORMULATION, EFFICACY, AND REGULATORY CONSIDERATION**

Vaishnavi Manapure and Shrushti Shrirao
School Of Pharmacy, G H Raisoni University, Saikheda, Madhya Pradesh, India 480337.
vaishnavimanapure53@gmail.com

The skin on the face is always under the pressure of the environment, as well as its pollution and general lifestyle practices which in most cases cause issues like skin drying, hyperpigmentation, elasticity loss, acne, and rough skin. In order to offer a comprehensive solution, a multifunctional natural derma serum derived and experimented in this research was prepared. This serum integrated conventional and modern methods in which Rice water, Centella asiatica extract, Panthenol (Vitamin B5), and Vitamin E were used as active ingredients, and the serum contained functional excipients like hyaluronic acid, xanthan gum, and appropriate preservatives. The preparation was done by extracting rice water followed by blending of the actives, homogenization and stabilization of the mixture. Serum developed was examined in regard to critical physicochemical characteristics such as appearance, pH, spreadability, viscosity, and stability. The PH was maintained in the skin-compatible range of 4.5-6.5 across multiple storage conditions, and viscosity and spreadability was facilitated by facilitating topical application. Stability test revealed no significant alteration in colour, texture and phase partition at refrigerated, intermediate and room temperature. The presence of bioactive markers namely asiaticoside and madecassoside was confirmed through Thin Layer Chromatography. Agar diffusion revealed that there was a significant moisturizing effect on the biological evaluation with less water loss as compared to control, mainly because of the synergistic activity of Panthenol and Rice water.

**Keywords:** Derma serum, Rice water, Centella asiatica, Panthenol, Hydration, Stability

**FORMULATION DEVELOPMENT AND EVALUATION OF NANOSUSPENSION LOADED AZELNIDIPINE TABLETS FOR THE TREATMENT OF HYPERTENSION**

Ailsinghani Tanvi Harin, Tandel Shrutiben Balvantbhai, Anuradha P. Prajapati, Sachin B. Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
tanviailsinghani123@gmail.com

Introduction**:** Azelnidipine, a calcium channel blocker of BCS Class II, widely prescribed for hypertension. However, its poor solubility and limited oral bioavailability restrict therapeutic effectiveness. Nanosuspension-based formulations provide promising strategy to enhance solubility and dissolution of poorly water-soluble drugs. Objective**:** To design and evaluate nanosuspension-loaded tablets of Azelnidipine to improve solubility, dissolution rate, and therapeutic efficacy in hypertension. Methodology**:** Nanosuspensions were prepared using media milling technique with Polyvinyl Pyrrolidone K30 (PVP K30) as stabilizer and Polyvinyl Alcohol (PVA) as surfactant. Total of thirteen formulations were prepared and evaluated for drug content, entrapment efficiency, particle size, PDI, zeta potential, solubility and in-vitro release. Results**:** Formulation F6 shows most optimal results, about 98.23% drug content, 86% entrapment efficiency, an average particle size of 129.9 nm, and favorable PDI of 0.117.This formulation achieved a drug release of 95.4%, notably higher than the 67.09% observed with pure Azelnidipine. The optimised nanosuspension was further formulated into immediate-release tablets, which shows rapid resolution and supports the efficiency of nanosuspension approach. Conclusion**:** The nanosuspension based immediate release tablets significantly improves the bioavailability and solubility of Azelnidipine. Such a formulation strategy could offer practical approach of achieving better therapeutic outcomes in patients with hypertension.

**FORMULATION AND EVALUATION OF BUCCAL FILM OF FINERENONE FOR CHRONIC KIDNEY DISEASE**

Aachal Kantilal Bhanushali, Bhoomi S. Patel , Anuradha Prajapati , Sachin Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
aachalbhanushali4444@gmail.com

This research is on development and evaluation of buccal film of Finerenone in chronic kidney disease (CKD). Finerenone is a newly approved non-steroidal mineralocorticoid receptor (MR) antagonist which has shown great potential to slow down CKD progression and reduce cardiovascular risk. But in current oral tablet formulations, its therapeutic efficacy is limited due to its low water solubility, poor oral bioavailability and short half-life. Finerenone is classified under Biopharmaceutics Classification System (BCS) CLASS II showing low aqueous solubility but high membrane permeability. In traditional oral dosage form, it is subjected to first-pass effect and cytochrome P450 (CYP) induction resulting in less than 50% oral bioavailability. Hence recent research on Buccal drug delivery as a new route. Buccal delivery avoids first pass metabolism and CYP induction and thus may maximize bioavailability and therapeutic response. In preparation, Hydroxypropyl Methylcellulose (HPMC) K100M and Carbopol 934 are used as main film forming polymers. Solvent casting method is used to prepare the film to ensure homogeneous distribution of the drug and integrity of the film. To further increase drug permeation through buccal mucosa, Polyethylene Glycol (PEG) 6000 is added as permeation enhancer and plasticizer. The final buccal film is designed to deliver controlled drug release, patient compliance and therapeutic performance through sustained release of drug for prolonged period. In general this buccal film delivery is a solution to the limitations of solubility and bioavailability of Finerenone and can be a better alternative to traditional oral tablet for CKD.

**Keywords:** Finerenone, Buccal film, HPMC K100M, Carbopol 934, chronic kidney disorder (CKD)

**Formulation and Evaluation of Cluster Bean Gum**

Mayuri Gajanan Zore
Department of Pharmacognosy, Gawande College of Pharmacy, Sakharkherda, Maharashtra India -443202
mgzore2049@gmail.com

Cluster bean is a very familiar produce in the Indian vegetable markets. Eighty per cent of the world's cluster bean is cultivated in our country, as the crop can tolerate both frequent rainfalls and arid conditions. However, this vegetable is comparatively less used in conventional cuisine. The promotion of cluster bean consumption through development commercial products would have great scope in the market. Three commercial products of cluster beans were developed namely bread spread, chutney powder and ready-to-cook curry mix. Five different formulations were worked out with various ingredients in different proportions. The best formulations were selected with respect to parameters such as appearance, colour, flavour texture, taste and overall acceptability by a sensory panel comprising of ten members. The products have scope to be commercialised in urban markets. Cluster bean (Cyamopsis tetragonaloba) is known to be helpful in reducing the blood glucose level in people suffering from diabetes mellitus and hypocholesterolemic subjects. Cluster beans were rich in soluble fibre content so they may be helpful in controlling hypercholesterolaemia. Cluster bean was processed and assessed to observe the hypoglycemic and hypocholesterolemic effect. Vegetable cluster beans and other ingredients were cleaned, dried and made into powder.

**Keyword:** Cluster Bean, Industrial qualities, Guar gum

**Development and Evaluation of Oral Dissolving Films of Leflunomide**

Pragathi Devanand Bangera a, Dhananjay Santosh Deshmukh a, Muralidhar Pisay a, Srinivas Mutalik a
a Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal 576104, Karnataka, India.
pragathibangera714@gmail.com

ISBN: 978-81-980623-8-3

Leflunomide (LEF), a disease-modifying antirheumatic drug (DMARD) prodrug, has both immunomodulatory and antiproliferative activities. FDA-approved in 1999, LEF is widely used to treat severe to moderate rheumatoid arthritis and other rheumatic diseases, successfully relieving pain, swelling, and joint deterioration. With such advantages, however, LEF is categorized as a BCS Class II compound with limited aqueous solubility, leading to low and variable oral bioavailability and erratic therapeutic effects. Accordingly, increased doses are needed for the desired efficacy, which escalates the risk of side effects. For overcoming these issues, a novel oral dissolving film (ODF) with a LEF–phospholipid complex (LPC) was formulated to enhance solubility and oral performance. The LPC was characterized by assessing particle size (PS), polydispersity index (PDI), zeta potential (ZP), complexation efficiency (%F), and solubility at different LEF and soya phosphatidyl choline ratios. Solid-state characterization of LPC and LPC-loaded ODF was analysed by DSC, FTIR, and XRD. The ODF was also evaluated for disintegration time, tensile strength, folding endurance, thickness, drug content, and in vitro release. Findings showed that LPC developed spherical particles with a mean diameter of 161.2 nm, zeta potential of –27.5 mV, and an entrapment efficiency of 87.47%. The ODF showed a tensile strength of 0.18 MPa and had fast release of the drug at pH 6.8. In general, results indicate that LPC has superior advantages compared to plain LEF, and its use in ODF improves the drug's physicochemical and biopharmaceutical performance.

**Keywords:** Disease-modifying Antirheumatic drug, Leflunomide, Phospholipid complex, Oral dissolving film.

## EXPLORATION OF DIRECTLY COMPRESSED PANTOPRAZOLE SODIUM TABLETS FOR TARGET SPECIFIC DRUG DELIVERY

Bhabani Sankar Mohanta*, Subhashree Sahoo, Bhupen Chandra Behera, Prakash Kumar Palai
Department of Pharmaceutics, Kanak Manjari Institute of Pharmaceutical Sciences, Rourkela, Odisha
Bhabanimohanta6@gmail.com

The present study focuses on the formulation and evaluation of pantoprazole sodium-loaded pH-sensitive floating tablets designed to minimize drug release in the acidic environment of the stomach and protect the drug from degradation. Utilizing a direct compression method, pantoprazole sodium, an acid-labile drug, was effectively incorporated into pH-sensitive polymers, particularly hydroxypropyl methylcellulose phthalate (HPMCP HP55), to achieve targeted site-specific drug delivery. Compatibility studies by FTIR indicate that there are no significant interactions between the excipients. Six formulations (IF1-IF6) of immediate release tablets were prepared using sodium bicarbonate, carbopol 940, CMC, magnesium stearate, and HPMC. Nine formulations (SF1-SF9) of sustained-release were prepared using HPMC K4M and HPMC K100M in different ratios and combinations by direct compression method. All formulations were evaluated for pre-compression and post-compression parameters. Various formulation parameters, including surfactant type and concentration, polymer-to-drug ratio, and phase ratios, significantly influenced the particle size, encapsulation efficiency, drug loading, and release profile of the developed systems. The study concludes that appropriate concentrations of HPMC, PEG, and sodium bicarbonate can be effectively utilized to develop gastroretentive floating tablets of pantoprazole sodium with sustained drug release and improved stability in the gastrointestinal tract.

**PC-191**

## FORMULATION, DEVELOPMENT AND EVALUATION OF NANOPARTICLES LOADED ORALLY DISINTEGRATING TABLETS CONTAINING FINERENONE

Tanvi R. Prajapati, Bansari B. Patel, Anuradha P. Prajapati, Sachin B. Narkhade
Smt. B.N.B. Swaminarayan Pharmacy College, Salvav- Vapi, India – 396191
tanvi051005@gmail.com

Finerenone is new-generation non steroidal drug used to manage chronic kidney disease (CKD) in people with type 2 diabetes. While it offers therapeutic benefits, its effectiveness is limited because it dissolves poorly in water and shows low oral absorption. To make the most of this drug, there is a need for smarter delivery approaches that can improve solubility and patient convenience. This study set out to create patient-friendly oral delivery system by incorporating Finerenone nanoparticles into orally disintegrating tablets (ODTs) to enhance drug dissolution and absorption while designing a tablet easy to take, especially for older patients or those with swallowing difficulties. Finerenone was converted into nanoparticles to improve how quickly it dissolves and how effectively the body can absorb it. These tiny particles were then used to create tablets that melt quickly in the mouth so they can be taken easily without needing water. The tablets were tested for their strength, how easily they crumble, how fast they break down and absorb moisture, how evenly the drug was spread, and how well the drug released in lab tests. The nanoparticle-based tablets were strong and dissolved quickly. Compared to regular tablets, they showed much better drug dissolution and solubility. Using nanoparticles helped the drug dissolve faster, which means the body can absorb it more easily, potentially making Finerenone work better. Finerenone nanoparticle-based ODTs overcome poor solubility, improve uptake, dissolve quickly, and enhance CKD patient comfort.

**Keywords**: Chronic kidney disease, nanoparticles, orally disintegrating tablets, bioavailability

**PC-192**

## DEVELOPMENT AND CHARACTERIZATION OF CO-AMORPHOUS SUBLINGUAL FILMS OF ILOPERIDONE, AN ANTI-PSYCHOTIC DRUG.

A. Lakshmi Usha
Department of Pharmaceutical Technology, Raghu College of Pharmacy, Visakhapatnam, A.P., India.
alakshmiusha@gmail.com

Iloperidone is an atypical antipsychotic, BCS Class II drug that is practically insoluble in water and is used in the treatment of Schizophrenia. In the present research work, the solubility of Iloperidone was enhanced by formulating into co-amorphous products (CAMs). The CAMs containing Iloperidone were prepared using the Solvent Evaporation technique, with citric acid (CA) and arginine (Ag) as co-formers. Furthermore, these CAMs were loaded into sublingual films utilizing HPMC K4M as polymer and Propylene glycol as the plasticizer. Drug content, saturation solubility, FTIR, XRD, DSC, and in-vitro dissolution tests were performed. A fivefold increase in solubility of the drug was shown by CAMs containing citric acid as a co-former of ratio 1:2. From the obtained in vitro release studies, citric acid (1:2) has shown maximum drug release of 88.9%. FTIR studies indicate a chemical interaction between Iloperidone and co-former resulting in the formation of co-amorphous product and justified by DSC studies. The in vitro disintegration time for the F1 and F2 films suggested that there would be faster drug release and faster oro-mucosal absorption. The in vitro dissolution test for F1 film showed a maximum drug release of 95%, at 15 min and the maximum drug release for F2 film was 93% which was observed by the end of 30min.

**Keywords**: Iloperidone, co-amorphous product, HPMC K4M, Propylene glycol, in vitro dissolution.

## PREPARATION AND CHARACTERISATION OF ATORVASTATIN CALCIUM LOADED NANOGEL AS TOPICAL GEL BASED FORMULATION

Kanakadandi Sitaramalakshmi and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
dattu712@gmail.com

Atorvastatin calcium (ATC) is characterized by poor oral bioavailability due to its low aqueous solubility and extensive first-pass metabolism. To address these limitations, the present study focused on developing an atorvastatin calcium nanogel (ANG) to enhance solubility, drug absorption, and bioavailability, while providing controlled release, localized delivery, and improved wound-healing efficacy. ATC nanocrystals (NCs) were prepared using a $2^3$ factorial design and solvent–antisolvent precipitation method, investigating the effects of stabilizer (Pluronic F-127), solvent–antisolvent ratio, and stirring time on NC characteristics. The optimized nanosuspension (F8) was incorporated

ISBN: 978-81-980623-8-3

into an aloe vera–carbopol gel base by magnetic stirring at 800 rpm to obtain the nanogel. The formulation was evaluated for transparency, smoothness, relative density, pH, moisture content, rheological behavior, spreadability, drug stability, and ex vivo permeability. Compared with the pure drug, the NCs exhibited significantly higher saturation solubility and a faster dissolution rate. The prepared gels (AG and ANG) were clear, viscous, and stable, with ANG showing a pH of 6.5, ensuring skin compatibility without irritation. The ANG demonstrated a viscosity of 8500 cps, indicating good thickness and residence time at the site of application. Ex vivo drug permeation revealed a 24-hour release of 50 ± 8 µg/cm² from AG, while ANG achieved a markedly higher release of 400 ± 18 µg/cm². Stability studies confirmed no significant changes after 90 days of storage. Overall, the results suggest that ATC-based nanogel provides sustained release, improved drug delivery, and better patient compliance due to its transparent, non-greasy, and user-friendly topical application.

**Keywords:** Atorvastatin Calcium, Nanocrystals, Solvent–Antisolvent Precipitation, Nanogel

## FORMULATION DEVELOPMENT AND EVALUATION OF BARICITINIB NANOEMULGEL

Mahek R Mahyavanshi , Kantilal B Narkhede, Sachin B Narkhade
Smt .B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
mahekmahyavanshi@gmail.com

This study will develop a topical gel made from a nanoemulsion to treat rheumatoid arthritis. It aims to be both effective and noninvasive. Baricitinib, a drug for rheumatoid arthritis, was incorporated into the nanoemulsion using Kolisolv GTA (Triacetin) as the oil phase, Tween as the surfactant, and Transcutol HP as the co-surfactant. This was achieved through the spontaneous emulsificationmethod.Preformulation experiments included FTIR and UV spectral analysis, an equilibrium solubility study, melting point determination, and a compatibility study with excipients. We validated the analytical method for Baricitinib in phosphate buffer at pH 7.4 and in distilled water using a UV spectrophotometer. We optimized the nanoemulsion formula using a 3^2 factorial design, where oil concentration (X1) and Smix concentration (X2) were the independent variables, and Zeta potential (Y1) and particle size (Y2) were the dependent variables.The optimized formula (F7 batch) had a particle size of 82.12 nm, a zeta potential of -20.12 mV, a drug content of 99.25%, and an in vitro release of 99.83% at 6 hours. We incorporated this optimized formulation into a gel made with Carbopol 940 and Triethanolamine to adjust the pH.The analysis of the nanoemulgel showed improved results for all parameters within specifications. We assessed the nanoemulgel for spreadability, viscosity, pH, and extrudability. The 30-day stability studies showed no sudden changes in physical appearance, FTIR spectra, or in vitro drug release, confirming the formulation's stability.

**Keywords:** Rheumatoid arthritis, Baricitinib, 32 Factorial Design and Nanoemulgel

**PC-195**

## FORMULATION AND EVALUATION OF NANO-GEL BY USING α, β-UN-SATURATED CARBONYL COMPOUNDS FOR THEIR ENHANCED ANTI-INFLAMMATORY AND ANALGESIC ACTIVITIES

Saniya Rouf Korbu, Pathan Muzakkir Ahmed, Dr. Shaikh Gazi, Dr. Mohammad Rayees
Dept. Of Pharmaceutics, RP College of pharmacy, Dharashiv, (M.H) 413501
Dept. Of Pharmaceutical Chemistry, RP College of pharmacy, Dharashiv, (M.H) 413501

Arthritis is a chronic musculoskeletal disorder characterized by inflammation of one or more joints, leading to pain, stiffness, swelling, and progressive loss of mobility. It is a major cause of disability worldwide, affecting over 350 million individuals, with osteoarthritis and rheumatoid arthritis being the most prevalent forms. Once regarded as a disease of aging, it is increasingly observed in younger adults (30–45 years) due to obesity, stress, and metabolic disorders. Conventional therapies, particularly NSAIDs, provide symptomatic relief but their long-term use is associated with gastrointestinal, renal, and cardiovascular adverse effects. To overcome these limitations, the research work mainly focuses in plant-derived formulations that are effective, safe, and suitable for long-term usage. Chalcones, naturally occurring flavonoids, exhibit anti-inflammatory and analgesic properties. Advanced delivery systems such as Nano-Gels can address these issues by improving solubility, retention, and targeted delivery. The innovation is formulated by a chalcone-loaded Nano-Gel, using cinnamon oil and eucalyptus oil for topical application in management of arthritis. Both oil contents cinnamaldehyde and 1,8-cineole, possesses potent anti-inflammatory and permeation-enhancing effects. These both oils not only provide therapeutic benefits but also act as natural penetration enhancers, enabling effective transport of chalcones into deeper joint tissues. The Nano-Gel was prepared via a Nano-emulsification technique, and is stabilized with surfactants using carbopol, and subsequently converted into a Nano-Gel, was evaluated by various parameters such as Nano Particle size Analyser (Horiba), scanning electron microscopy (SEM), consistency, spreadability and viscosity tests. The Pharmacological in-vitro test was confirmed for their Anti-inflammatory and analgesic activities.

**Keywords:** Arthritis, Chalcones (α,β-un-saturated carbonyl compounds), Cinnamon oil, Eucalyptus oil, Nano-Gel, Anti-inflammatory, Natural penetration enhancers.

## FORMULATION AND IN VITRO-IN VIVO EVALUATION OF DAPOXETINE HCL NANOPARTICLES CAPSULE

Sathiya Kovaiselvan*, Selvakumar muruganantham
Department of pharmaceutics, Vivekanandha Pharmacy College for Women, Sankari, Salem – 63637303. Tamil Nadu, India
sathiyavedha2003@gmail.com

The purpose of the present study was formulation and in vitro-in vivo evaluation of Dapoxetine HCL nanoparticles loaded in the capsule shell. The objective is to increase the dissolution, half-life, and stability by decreasing the particles size, thereby improving bioavailability, and therapeutic efficacy. The nanoparticles were prepared using solvent evaporation method using different polymers (Ethyl cellulose, Chitosan, HPMC K100, Betacyclodextrin) with four different ratios. The best formulation among all sixteen were determined by comparing the theoretical yield, drug content, entrapment efficiency and invitro drug release. F6 was considered as the best formulation as it had entrapment efficacy as 90.94% and drug release was 96.93% upto 12 hours. The best formulation was characterized for its particle size, polydispersity index, zeta potential, drug entrapment efficiency, particle morphological characters (SEM and PXRD) and for anti-depressant activity in vivo. Dapoxetine Hcl nanoparticles (F6) shown better anti-depressant activity than the control, pure drug and Imipramine (standard) treated animal. Dapoxetine Hcl nanoparticles (F6) loaded in to capsule shell by hand filling method using micro crystalline as a binder and diluents, magnesium stearate as lubricant. Finally, to compare the Invitro release studies of Dapoxetine Hcl Nanoparticle Capsule (F6) with Dapoxetine Hcl Capsules.

**Keywords:** Dapoxetine Hcl, Ethyl Cellulose, Chitosan; HPMC K100, Betacyclodextrin, Nanoparticles.

## DIFLUPREDNATE IN-SITU NANOGEL FOR ANTERIOR UVEITIS. AND POST-OPERATIVE OCULAR INFLAMMATION

Ghanshamdas Bairagi, Vandana Patravale
Department of Pharmaceutical Sciences and Technology, Institute of Chemical Technology, Matunga, Mumbai, Maharashtra, India 400019.

Difluprednate (DFBA), a potent corticosteroid and difluorinated prednisolone derivative, is widely used for treating post-operative ocular inflammation and anterior uveitis. It acts by reducing vasopermeability, redness, edema, and pain while uniquely sequestering leukocytes from inflammatory sites. DFBA's active metabolite shows significantly higher glucocorticoid receptor affinity than prednisolone. Durezol, a 0.05% DFBA eye drop, is the reference listed drug (RLD), typically administered four times daily. To enhance patient compliance and therapeutic efficacy, this study developed a stable in-situ gel formulation of DFBA with sustained-release properties. Utilizing FDA-reviewed composition data, a coarse emulsion was prepared with 0.5% w/w gellan gum (GG), and further processed using a microfluidizer at 25,000 PSI for 9 cycles to obtain a nanoemulsion (NE). The resulting NE had a globule size of 91.55

ISBN: 978-81-980623-8-3

± 10 nm, PDI of 0.207 ± 0.06, and zeta potential of -6.58 ± 0.11 mV. Drug content, entrapment efficiency, drug loading, pH, and osmolality were found to be 98.55 ± 3.64%, 87.24 ± 2%, 0.044 ± 0.03%, 5.8 ± 0.2, and 283 mOsm/kg, respectively. Both DFBA-NE and in situ gelling DFBA-NE exhibited sustained drug release over 4 days—95 ± 2.4% and 90.28 ± 1.3%, respectively—outperforming the marketed DFBA eye drop and suspension in release, corneal permeation, and retention. The in-situ gel formulation remained stable for over 12 hours in simulated tear fluid, indicating potential for reduced dosing frequency and improved patient adherence. HET-CAM assay results confirmed non-irritancy, sterility was preserved, and 3-month stability studies demonstrated sustained physical stability.

**Keywords:** Difluprednate, nanoemulsion, microfluidizer, Ocular inflammation, Sustained release.

**INVESTIGATION OF TRIPLE-RESPONSIVE NEEM FACE WASH GEL**

Mitali Soren, Subhashree Sahoo
Department of Pharmaceutics, Kanak Manjari Institute of Pharmaceutical Sciences, Rourkela, Odisha
sorenmitali75@gmail.com

In this current study design, the investigation of triple-responsive face wash gel using aqueous extract of Neem leaves has been carried out. In the world of Ayurveda, Neem (Azardirachta indica) or "Divine tree" is well liked medical herb that has been a part of traditional remedies to treat acne and pimple. A novel triple-responsive gel constructed by emulsion polymerization of photo-responsive spiropyran methacrylate (SPMA), temperature-sensitive N-isopropylacrylamide (NIPAM), and pH-responsive methacrylic acid (MAA). The prepared Neem face wash gel was evaluated for parameters like color, pH, consistency, washability, grittiness, foamability, and spreadability. It was found that gel has been found to be slightly yellowish in colour, gel viscosity of 1748 cp, spreadability 7.5 g.cm/sec, semi-solid in consistency, easily washable, pH 6.15 compatible to skin, foam volume of 92 ml at 5 minutes. The system exhibited reversible volume change in response to pH, temperature, and near-infrared (NIR) light. TLC for extraction method exhibit bands in long UV 366 nm for presence of bioactive compounds like flavonoids. They offer a range of benefits, including stability of extract constituent enhancing the bioavailability, oxidative stress reduction, inflammation modulation, and DNA damage prevention. Thus, it can be concluded that the effectiveness of neem face wash smart gel believed to be act on multiple targets, enhancing anti-acne, antioxidant and anti-inflammation properties with triple response. However, the challenge remains in deciphering the complexity of herbal compounds and their mechanistic pathways.

**Keywords:** Face wash gel, Neem, triple-responsive, anti-inflammation, anti-acne.

**FORMULATION AND EVALUATION OF ELLAGIC ACID-LOADED POLYMERIC NANOPARTICLES FOR ANTIDIABETIC AND ANTICANCER ACTIVITY IN MCF-7 CELLS**

Loganayagi Venkatachalam and Dhanasekar Jayakumar
Vivekanandha Pharmacy College for Women, Veerachipalayam, Salem (Dt), Tamil Nadu, India- 637 303.
loganayagivenkat9486@gmail.com

Ellagic acid is a naturally occurring polyphenolic compound found in various plants, known for its antidiabetic, anticancer, and antioxidant properties, and associated with multiple health benefits. However, ellagic acid exhibits poor solubility and stability in the gastric environment, along with low permeability across biological membranes, resulting in limited bioavailability. To overcome these limitations, ellagic acid has been encapsulated into polymeric nanoparticles (PNPs) to enhance its solubility, permeability, stability, and overall bioavailability. In this context, an advanced strategy has been developed to formulate and characterize hyaluronic acid surface-functionalized ellagic acid-loaded chitosan-soya lecithin–TPGS-based nanoparticles using a molecular self-assembly approach to improve oral bioavailability and therapeutic efficacy. Polymeric nanostructures provide protection to ellagic acid and enable targeted delivery to specific tissues and cells. Recent investigations have reported the formulation and evaluation of ellagic acid-loaded PNPs for antidiabetic activity in rat models and anticancer activity in breast cancer cell lines such as MCF-7. This nanoparticle-based delivery system combines the therapeutic potential of polyphenols with nanotechnology to improve efficacy and broaden biomedical applications, including pharmaceuticals and functional foods.

**Keywords:** Ellagic acid, Polymeric nanoparticles, Hyaluronic acid functionalization, Antidiabetic activity, MCF-7 breast cancer cells.

**DEVELOPMENT AND CHARACTERIZATION OF SODIUM FUSIDATE NIOSOMAL INSITU GEL FOR OCULAR DRUG DELIVERY**

Pingali Haarini and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
haarini311@gmail.com

This study aimed to develop and characterize a niosomal in-situ gel system for ocular delivery of Fusidic Acid to enhance drug retention and bioavailability in the management of ocular infections. Niosomes were prepared using Thin Film Hydration (TFH) and Ether Injection (EI) methods, with TFH yielding superior drug content (DC) and entrapment efficiency (EE), and thus selected for further optimization. The optimized niosomal formulation (F8) was incorporated into in-situ gels using the cold method with varying concentrations of Pluronic F-127 and NaCMC, resulting in six batches (F1–F6). Physicochemical and performance evaluations included vesicle size, zeta potential, viscosity, gelation temperature, drug content, in vitro release, antimicrobial activity, sterility, and stability. The optimized formulation (F8) exhibited a mean vesicle size of 317 nm with uniform spherical morphology and a zeta potential of –46.4 mV, confirming stability due to strong electrostatic repulsion. The gels were homogeneous, lump-free, and demonstrated viscosity values of 504–704 cps with pH ranging between 6.2 and 6.8, ensuring ocular safety. Drug content ranged from 96.72% to 98.32%, indicating uniformity, while in vitro studies showed sustained release influenced by polymer concentration. Among all batches, F5 exhibited the most prolonged drug release profile. Sterility testing confirmed the absence of microbial contamination, and stability studies showed no significant changes under storage. Overall, Fusidic Acid niosomal in-situ gels demonstrate great potential as a novel ocular delivery system, overcoming the limitations of conventional eye drops by providing controlled release, reduced dosing, and improved patient compliance.

**Keywords:** Fusidic Acid, Niosomes, Thin Film Hydration Method, In-Situ Gel, Cold Method, Ocular Drug Delivery.

**PC-201**

**FORMULATION AND EVALUATION OF FINERENONE EXTENDED-RELEASE TABLETS USING EUDRAGIT RS100 AS A MATRIX FORMER: A COMPARATIVE STUDY WITH HPMC-BASED FORMULATIONS**

Neel Desai, Bhanushali Mayank Ratilal, Kantilal Narkhede, Sachin Narkhede
Smt B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191

The present study was aimed at developing and evaluating extended-release matrix tablets of Finerenone which is a novel non-steroidal mineralocorticoid receptor antagonist, which uses Eudragit RS100 as the matrix-forming polymer. Finerenone is currently marketed as immediate-release tablets (Kerendia®) for the management of chronic kidney disease (CKD) which is associated with type 2 diabetes mellitus (T2DM) and requires daily administration. Developing an ER formulation could sustain therapeutic levels and reduce dosing frequency, and also improves patient adherence in chronic therapy. The hydrophobic, water-insoluble, yet permeable properties of Eudragit RS100 were chosen because they minimize the impact of gastrointestinal pH and motility on drug release, which is advantageous for poorly soluble medications. Direct compression was used to create these formulations, and pre- and post-compression parameters were assessed. The tablets hardness, friability, thickness, weight fluctuation, uniformity of drug content and in vitro release in gastrointestinal fluids were evaluated. The release profile of formulation of Eudragit RS100 was tested and compared with that of traditional HPMC hydrophilic matrix system. Compared to HPMC matrices, which are prone to variations due to agitation, the ionic environment, and gel strength, Eudragit RS100 formulations provide

ISBN: 978-81-980623-8-3

more stable, pH-independent, and controlled release profile. Stability tests was performed according to ICH guidelines which shows the robustness of the optimized formulation. Finally it was shown that ER finerenone tablets based on Eudragit RS100 has better control over drug release. This could result in better adherence, fewer doses, and increased therapeutic efficacy in the long-term management of CKD with type 2 diabetes

**Keywords:** Finerenone, Extended-release tablets, Eudragit RS100, HPMC matrix, Controlled drug delivery

**FORMULATION OPTIMIZATION AND EVALUATION OF NANOSUSPENSION OF ETODOLAC**

Pravin Kumar Sharma, Pooja Prajapat, G. N. Darwhekar
Acropolis Institute of Pharmaceutical Education and Research, Indore (M.P), India - 453771
praveensharma910@gmail.com

Etodolac is a NSAID, which belongs to BCS class II and it exhibits low oral bioavailability (~ 40%) due to poor aqueous solubility. The objective of present research work was to formulate and optimize nanosuspension of Etodolac to improve solubility and dissolution profile. The preformulation studies such as λ max determination, preparation of calibration curve, determination of saturation solubility and drug excipient compatibility study using DSC were carried out. Nanosuspension of Etodolac was prepared by anti-solvent precipitation method and optimized using box behnken design to study the effect of independent variables like concentration of HPMC, concentration of SLS and concentration of urea on dependent variables like saturation solubility and % drug content. On the basis statistical analysis using DoE, the optimized formula was obtained, which was further evaluated based on saturation solubility (16.37 ± 1.21 mg/ml), % drug content (86.57 ± 1.82 %), particle size (650.45 ± 2.56 nm), zeta potential (-6.9 ± 1.2 mV), pH measurement (pH 4.86 ± 0.46), in-vitro % drug release (98.91 ± 0.53 % upto 4 hours) and stability study (found stable up to 3 months). Based on the results, it was concluded that aqueous solubility of Etodolac was found to be remarkably increased in form of nanosuspension, suggesting the potential for improvement in oral bioavailability.

**Keywords:** Etodolac, nanosuspension, anti-solvent precipitation method, solubility enhancement, Box-Behnken design.

**PC-203**

**STATISTICAL OPTIMIZATION OF ORODISPERSIBLE TABLETS OF FEXOFENADINE HYDROCHLORIDE SOLID DISPERSIONS BY BOX-BEHNKEN DESIGN**

Department of Pharmaceutics, Vignan Institute of Pharmaceutical Technology(A), Andhra Pradesh, India -530049.
Bhsrivaishnavi23@gmail.com

Fexofenadine, used as an anti-histaminic drug with low solubility has absorption problems. Fexofenadine HCL, an anti-histamine drug is used for treating hay fever and allergy,belongs to BCS Class-II and has low solubility. In the present work solid dispersions of fexofenadine Hcl were prepared using cyclodextrin and PVP as carriers to improve solubility. These solid dispersions were formulated into orodispersible tablets using cyclodextrin and PVP in different ratios. The solid dispersions showing good solubility were used to prepare orodispersible tablets using Sodium starch glycolate, Vee Gum and croscarmalose sodium as super disintegrants , the formulations were optimised using statistical design by Box - behnken method. The optimised formulation suggested by the software, combining of SSG,CCS and Vee Gum showed 88 % of drug release within 15 minutes, which is nearly equal to the value predicted by the software. Thus, converting the drug into a solid dispersion increased its solubility, and further formulation into orodispersible tablets using superdisintegrants resulted in a high drug release rate of 88%. The FTIR studies showed no interaction between the drug and cyclodextrin,PVP.

**Keywords:** Fexofenadine HCL, orodispersible, Box – behnken, cyclodextrin, disintegrants.

**INNOVATIVE HYDROGEL FORMULATION FOR ENHANCED DELIVERY OF MORINGA AND BRAHMI**

Rutuja Kumare, D. L. Bawankar and S. W. Lohe
Department of Pharmaceutics, Anurag College of Pharmacy, Bhandara, Maharashtra, India-441905
rutukumare316@gmail.com

Wound healing is a natural, complex, and essential physiological process that occurs after the skin or other tissues are damaged. Natural extracts of medicinal plants have been used for centuries in traditional healing systems like Ayurveda, Siddha, and Traditional Chinese Medicine because of their anti-inflammatory, wound-healing, and antioxidant qualities. Bacopa monnieri (Brahmi) and Moringa oleifera (Drumstick Tree) can speed up wound healing, enhance cognitive function, and encourage tissue regeneration. The plant's anti-inflammatory properties help reduce swelling and pain at the wound site, creating an environment conductive to healing. The study was conducted on leaves of Moringa oleifera and Bacopa monnieri. These powerful botanical extracts can now be incorporated into hydrogel-based medication delivery systems thanks to advancements in biomaterials. This research aims to develop a novel alginate-based hydrogel with Brahmi and Moringa extracts for better topical use.The extraction of Moringa oleifera was carried out through Soxhlet method and extraction of Bacopa monnieri was carried out through Maceration techniques. The present study successfully developed and evaluated herbal-based hydrogel formulation incorporating Brahmi and Moringa extracts for wound healing applications. The formulation was refined to guarantee the active phytoconstituents stability, bioavailability, and extended release. The potential advantages of its hydration, bioactive retention, and cell regeneration-promoting capabilities were assessed.The results suggest that such natural hydrogel systems can serve as a safe, effective, and eco-friendly alternative to conventional wound care products. This study demonstrates how contemporary hydrogel technology and traditional herbal knowledge can be combined to create novel medicinal compositions for the next generation.

**Keywords:** Hydrogels, Biopolymers, Drug Delivery, Moringa oleifera, Bacopa monnieri.

**DESIGN AND EVALUATION OF VARDENAFIL LOADED SELF NANOEMULSIFYING CHEWABLE TABLETS**

Surti Yukti Manish, Naik Neel Snehal, Kantilal Narkhede
Smt B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
Surtiyukti2006@gmail.com

The primary objective was to formulate and develop Self Nanoemulsifying Chewable Tablets of Vardenafil. Vardenafil is used for treatment of erectile dysfunction in men. It is classified under the medications known as phosphodiesterase (PDE) inhibitors. The formulation Cinnamon Oil as oil, Tween 80 as surfactant and PEG 400 as co-surfactant. This experiment underwent a 32 Full factorial design for formulation optimization. According to the design, 2 factors were evaluated, each at 3 levels, and experimental trials were conducted at all 9 combinations. Pseudo ternary phase diagram supported the selection of 2:1 ratio. Independent factors were the Concentration of Oil (X1) and the Concentration of Smix (Tween 80:PEG400) (X2). Zeta potential, Self Emulsification time and % Transmittance were taken as the dependent variables. Results were benchmarked against checkpoint batch. From overlay plot, concentration of the Cinnamon oil was determined as 20% (0.16ml) and S-mix 80% (0.83 ml). Optimized Formulation demonstrates a particle size of 89.9nm, % Transmittance of 98.25%, Zeta potential of -2.9mV and a polydispersibility index of 0.23. The liquid SNEDDS was transformed to S-SNEDDS with Neusilin acting as the adsorbent. Finally, S-SNEDDS was transformed into chewable tablets through wet granulation. This formulation exhibited a drug release of 97% within 1 hour. SNECT demonstrated improved drug formulation.

**Keywords:** Vardenafil, Self-Nanoemulsifying Drug Delivery System (SNEDDS), Chewable Tablets, Factorial Design, Bioavailability Enhancement

**PC-206**

**FORMULATION AND EVALUATION OF CHITOSAN BASED POLYMERIC NANOPARTICLES OF AN ANTI - ALZHEIMER'S DRUG MEMANTINE HYDROCHLORIDE**

Tanniru Sirisha and Sadhu Venkateswara Rao

ISBN: 978-81-980623-8-3

Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women

sirishasirishat6@gmail.com

The aim of the study was to develop Memantine HCl loaded chitosan - sodium tripolyphosphate (STPP) nanoparticles using Ionic gelation method and evaluates their physicochemical properties and in-vitro release studies for possible targeted delivery to the brain. The objective was to fabricate polymeric nanoparticles for better controlled and targeting action of drug, which also overcome the problems associated with conventional formulations like multidose therapy, poor patient compliance and high cost. Memantine HCl loaded chitosan nanoparticles (F1 to F6) were prepared by Ionotropic gelation method. The formulated nanoparticles were evaluated for external morphological characters, determination of particle size analysis, zeta potential, drug content, entrapment efficiency and in-vitro release studies. The particle size varied from 148 to 317 nm and zeta potential was in negative and its value found to be - 46.4 mV. The drug content for the Memantine HCl loaded chitosan nanoparticles varied from 69.5 ± 7.2% to 87.9 ± 1.2%. The entrapment efficiencies were found to be minimum and maximum of 55.50 ± 2.4% and 86.30 ± 3.6%. The percentage yields of all formulations were in the range of 48.24 ± 1.24 to 86.13 ± 1.37%. In-vitro release of drug follows zero order and showed sustained release behaviour for a period of 24 hr. The optimized formulation contains 3:1 ratio of chitosan & STTP and demonstrated successful sustained release. Memantine HCl loaded chitosan nanoparticle is a potential new delivery system for treatment of Alzheimer's disease.

**Key words**: Alzheimer's disease, Polymeric nanoparticles and Ionotropic gelation.

**PC-207**

**TARGETING PSORIASIS WITH DIOSCOREA BULBIFERA EXTRACT-LOADED NANOGEL: IN-VITRO CHARACTERIZATION & IN-VIVO STUDY IN RAT MODEL**

Neelam Singh, R.K. Roy
HR Institute of Pharmacy, HRIT University, Ghaziabad, India

This study explores the development of a nanostructured lipid carrier (NLC) system incorporating Dioscorea bulbifera root extract for the topical treatment of psoriasis. The NLC formulation, composed of soy wax as the solid lipid and karanj oil (Pongamia pinnata) as the liquid lipid, was prepared using the hot melt method and embedded into a Carbopol 934-based gel. A Box–Behnken experimental design was employed to optimize the formulation across sixteen experimental runs. Characterization of the NLC and nanogel was performed using diosgenin as a biomarker. In vivo evaluation using a rat model of imiquimod-induced psoriasis revealed effective drug encapsulation and significant anti-psoriatic activity. Compared to a plain extract gel, the nanogel demonstrated faster therapeutic action, sustained drug release over 12 hours, and a marked reduction in inflammatory markers IL-23 and IL-17. Histopathology examination reveals cytoarchitectural recovery of psoriatic skin. Indicating the regenerative potential of the Dioscorea bulbifera-based nanogel formulation. These results establish Dioscorea bulbifera as an intriguing option for psoriasis treatment, deserving of more clinical research to confirm its effectiveness and safety in people.

**Key words**: Dioscorea bulbifera, NLC, psoriasis, inflammatory markers, diosgenin

**PC-208**

**DESIGN AND EVALUATION OF VERAPAMIL HCL CAPSULES CONTAINING IMMEDIATE AND EXTENDED-RELEASE PELLETS**

Chetna Omaram Mali, Nitin Eknath Patil, Kantilal Narkhede, Sachin Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
chetnaomali0905@gmail.com

Hypertension remains one of the most prominent risk factors contributing to the disease burden in India and requires effective long-term control and management. One of the medications used in the treatment of hypertension is Calan SR prescribed Verapamil HCl. There are various sustained release (SR) formulations in the market. The objective of the current study was to develop and evaluate Verapamil HCl containing both Immediate Release (IR) and Extended Release (ER) layers in pellets form to both rapidly achieve therapeutic levels in the system and maintain them subsequently. The IR and ER pellets were fabricated using the powder layering and wurster coating techniques. The release-rate controlling coating Surelease (ethyl cellulose) along with Eudragit S 100 and Eudragit L 100 as pH-dependent polymers for ER were selected based on preliminary screening. Release kinetics were predefined using $3^2$ factorial design to achieve optimized formulation. The optimized batch F4 showed satisfactory physical and analytical parameters with biphasic release comprising simulated loading dose followed by zero-order rate controlled maintenance dose for 24 hours. The study concludes that the formulated capsule is capable of improving patient adherence by lowering the dosing frequency to once daily while ensuring steady therapeutic plasma concentrations of Verapamil HCl.

**Keywords:** Hypertension, Verapamil HCl, Immediate release, Extended release, Pellets

**DEVELOPMENT AND OPTIMIZATION OF ORO-DISPERSIBLE FILMS OF LAMOTRIGINE-B CYCLODEXTRIN COMPLEX: EFFECT OF LYCOAT RS 720 AND SSG CONCENTRATION ON FILM DISINTEGRATION**

Kamakshi R.S. Kunkolienker and Pearl Dighe
Department of Pharmaceutics, P.E. S's Rajaram and Tarabai Bandekar College of Pharmacy, Farmagudi, Ponda,Goa, India-403401
Kamakshi1052@gmail.com

Lamotrigine is an antiepileptic drug belonging to Phenyltriazine class. It being a BCS Class II drug necessitates it to be formulated in a dosage form which improves its solubility. In the current research work, Oro-Dispersible films (ODF) of Lamotrigine-β Cyclodextrin (LMN-βCD) complex using PVA as a film forming agent for the treatment of epilepsy were formulated. ODF of LMN-βCD (1:1) were prepared by the solvent-casting method; using PVA and Lycoat RS 720 combination as film forming agents, PEG was used as a plasticizer, SSG was used as a super-disintegrant, citric acid was used as a saliva stimulating agent. The objective behind the research was to examine the effect of the concentrations of the of Lycoat RS 720 polymer and SSG on the disintegration time and % CDR at 10 minutes of the PVA films. A 32factorial design was used for optimization where three different concentrations of the Lycoat RS 720 and SSG were used as independent factors and disintegration time and % CDR at 10 minutes were taken as dependent responses. The overall study concluded that addition of Lycoat RS 720 and SSG in suitable concentration to the PVA formed LMN-βCD complex films can improve the disintegration time and % CDR considerably.

**Keywords:** Lamotrigine, Lycoat RS 720, 32factorial design, Oro-Dispersible film.

vaishnaviss192@gmail.com

Dual-release mechanism of ethosomal gels (i.e., ethosomes and gel) makes them as versatile drug delivery systems for topical applications. Berberine (BER) is the primary active alkaloid extracted from Coptidis Rhizoma, which has many pharmacological actions. This study aimed to develop and evaluate an ethosomal gel containing berberine (BER) for treating candidiasis. The researchers formulated BER-loaded ethosomes using a modified cold technique with varying concentrations of soy lecithin (1-3%) and ethanol (10-40%). The resulting ethosomes were assessed for characteristics like vesicle shape, size, electrical charge (zeta potential), and BER entrapment efficiency. Subsequently, the optimized ethosomes were integrated into a carbopol 934 gel base. The formulated ethosomal gels underwent further evaluation for spreadability, drug release profile, ex vivo permeation through skin layers, and antifungal activity against Candida albicans compared to standard ketoconazole. Notably, the optimized formulation exhibited a skin-friendly pH, minimizing potential irritation. The encouraging antifungal activity against C. albicans suggests promise for this novel delivery system in topical treatment of candidiasis.

**FORMULATION AND DEVELOPMENT OF RIBOCICLIB NANOCARRIER FOR THE TREATMENT OF BREAST CANCER**

Anjali Patel1,2, Mohammad Adnan Raza1,2, Ajazuddin1,2
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023

Breast cancer remains one of the most prevalent malignancies among women worldwide, with limitations in conventional chemotherapeutic approaches often attributed to poor drug solubility, systemic toxicity, and multidrug resistance. Ribociclib, a selective cyclin-dependent kinase 4/6 (CDK4/6) inhibitor, has shown significant clinical promise in the management of hormone receptor-positive (HR+), human epidermal growth factor receptor-2 negative (HER2–) breast cancer. However, its therapeutic efficacy is hindered by issues such as limited bioavailability and dose-dependent adverse effects. Nanocarrier-based drug delivery systems provide an advanced platform to overcome these barriers by enhancing solubility, prolonging systemic circulation, improving tumor-specific accumulation, and reducing off-target toxicity. The present work focuses on the formulation and development of ribociclib-loaded nanocarriers, employing techniques such as nanoprecipitation or lipid-based encapsulation for optimal entrapment efficiency, stability, and controlled drug release. Characterization parameters include particle size, polydispersity index, zeta potential, encapsulation efficiency, and in vitro release kinetics, along with cytotoxicity assays on breast cancer cell lines to evaluate therapeutic potential. The proposed nanocarrier system aims to maximize ribociclib's bioavailability and antitumor activity while minimizing systemic side effects, thereby offering a promising approach in the targeted treatment of breast cancer.

**Keywords**: Breast cancer, Bioavailability, Nanocarrier, Ribociclib, CDK4/6 inhibitor.

**PC-212**

**DEVELOPMENT AND CHARACTERIZATION OF VALSARTAN PRESS COATED TABLETS FOR CHRONOTHERAPEUTIC DRUG DELIVERY SYSTEM**

Domathoti Beaulah Shalemu Rani and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
domathotishalem@gmail.com

The present study aimed to develop a chronotherapeutic drug delivery system for Valsartan using the press coating technique to enhance treatment efficacy in managing hypertension through controlled and time-dependent drug release. Valsartan's solubility was improved via solid dispersion techniques, with formulation F6 (solvent evaporation method) showing the highest saturation solubility (0.55 mg/mL). Fast-dissolving core tablets were prepared using the direct compression method, employing croscarmellose sodium and sodium starch glycolate as coprocessed superdisintegrants. Six formulations (F1–F6) were developed using varying concentrations (5%, 10%, and 15% w/w) of the superdisintegrants. Among these, F3 containing 15% croscarmellose sodium exhibited the fastest drug release. The optimized fast-dissolving core (F3) was then used to formulate press-coated tablets with HPMC K-100 and ethyl cellulose (EC) in different ratios. The coating was designed to achieve a specific lag time before drug release, ideal for chronotherapeutic applications. The mechanism involves erosion or dissolution of the coating layer, enabling delayed release from the core. Dissolution studies were carried out in 0.1 N HCl for 2 hours, followed by phosphate buffer (pH 6.8) for 12 hours. The press-coated formulation containing 350 mg EC and 50 mg HPMC K-100 exhibited the desired drug release profile, with a lag time of 3–3.5 hours and sustained release thereafter. The developed system has potential to reduce dosing frequency and enhance therapeutic outcomes in hypertension management.

**Keywords:** Valsartan, Chronotherapeutic, Press coating, Lag time and Hypertension

**PC-213**

**FABRICATION AND CHARACTERIZATION OF RUTIN SOLID LIPID NANOPARTICLES AS POLYPHENOL NANOCARRIERS FOR THE ENHANCEMENT OF ANTI-ARTHRITIC ACTIVITY**

Lathamani Lakshmanan* and Rathnamoorthi Velusamy
Department of Pharmaceutics, Vivekanandha Pharmacy College for Women, Salem, Tamilnadu, India – 637 303

In the current research, Rutin-loaded Solid Lipid Nanoparticles (R-SLNPs) were fabricated using tripalmitin, TPGS, and Soya lecithin to enhance Rutins anti-arthritic activity. Rutin, despite its efficient anti-arthritic activity suffers from poor water solubility, instability in acidic conditions, limited oral absorption in the gastrointestinal tract and poor bioavailability. The objective behind this research was to enhance the solubility of Rutin by formulating as Solid lipid nanoparticles and making it a suitable candidate for the treatment of arthritis. Rutin showed low water solubility but higher solubility in organic solvents. FT-IR confirmed its compatibility with polymers, and UV analysis validated drug's purity. SEM analysis showed smooth, spherical particles within the desired size range (175.6nm). A negative zeta potential (-24.7 mV) and low polydispersity index (0.348) suggested physical stability and target specificity**.** R-SLNPs exhibited high entrapment efficiency (85.25%) and biphasic release patttern, with an initial burst at 2 hrs followed by sustained release upto 72 hours, consistent with Higuchi diffusion kinetics. TPGS-functionalized R-SLNPs showed enhanced anti-inflammatory effects and joint protection in a rat arthritis model. Stability studies revealed higher stability under refrigeration conditions (4°C±2°C / 60%RH±5%) compared to ambient and accelerated conditions. Histopathological and biochemical analyses supported the anti-inflammatory effects and improved kidney function with R-SLNP treatment. This study concludes that Rutin-loaded SLNPs, particularly TPGS-functionalized hold promises for arthritis therapy, offering enhanced solubility, bioavailability, and stability, with potential for scalable production.

**Keywords**: Rutin, Solid lipid nanoparticles, Polyphenols, TPGS, Anti-arthritic activity.

**PC-214**

**SMART NANOTECH PATCHES: A PAIN FREE FUTURE FOR DIABETES CURE**

ZOHA HUSSAIN

India is the epicenter of a diabetes crisis, with over 101million adults currently affected and millions more at risk. conventional insulin therapy depends on multiple daily subcutaneous injections, which are painful, inconvenient and often lead to poor adherence. This unmet need calls for innovative, patient friendly and affordable approaches tailored to the Indian context. This project explores the integration of nanotechnology based microneedle patches with artificial intelligence driven dosing algorithms to create a pain free, smart and accessible alternative to insulin injections for diabetes management. We propose the development of dissolvable polymeric microneedle patches loaded with insulin-loaded nanocarriers to enable controlled, transdermal drug delivery. preclinical evaluations will focus on drug permeation, biocompatibility and glycemic control in diabetes. While usability and stability will assess suitability for Indias diverse climate and healthcare settings. This approach has the potential to transform diabetes care in India by reducing complications, improving quality of life and lessening the economic burden on patients and healthcare system.This innovation represents a step toward an indigenous solution that aligns with India's vision of affordable and patients centric healthcare. Pain free insulin delivery with minimal skin irritation. It is cost effective, scalable technology and is adaptable for Indian pharamaceutical manufacturing.

**DEVELOPMENT OF A HYDROTROPIC SOLID DISPERSION-BASED TABLET TO ENHANCE SOLUBILITY OF A POORLY SOLUBLE DRUG**

Pooja R. Gawandar and Dr. Kailash R. Biyanai
Department of Pharmaceutics, Anuradha College of Pharmacy, Chikhli,Dist Buldhana, Maharashtra, India- 443101
poojagawandarsaj@gmail.com

Limited solubility in water presents a significant obstacle in creating oral dosage forms for numerous therapeutic agents, consequently affecting their bioavailability and therapeutic efficacy. This study aims to

ISBN: 978-81-980623-8-3

formulate a hydrotropic solid dispersion-based tablet to improve the solubility and dissolution rate of a drug that is poorly soluble in water, utilizing sodium salicylate as a hydrotropic solubilizer. Initially, solubility studies were performed with different concentrations of sodium salicylate to identify the most effective hydrotropic concentration. Solid dispersions of the target drug were fabricated using the solvent evaporation technique, where the drug was first solubilized in sodium salicylate, followed by the evaporation of the solvent to yield the solid dispersion. The resulting solid dispersions were assessed for drug content, flow characteristics, compatibility, and possible molecular dispersion. Tablets were created utilizing the direct compression method along with suitable excipients. The resulting tablets underwent evaluation based on standard parameters such as hardness, friability, weight variation, disintegration time, and in-vitro dissolution assessments. The drug's solubility notably improved with the inclusion of sodium salicylate, and solid dispersions demonstrated better dissolution profiles when compared to the unprocessed drug. Among the various formulations developed, the batch containing solid dispersion made with 2M sodium salicylate showed the highest drug release (exceeding 90% within 45 minutes), in contrast to less than 30% for the unprocessed drug. The study concludes that the use of hydrotropic agents like sodium salicylate in the preparation of solid dispersions**,** followed by tableting, is a promising and simple approach to enhance the solubility and dissolution of poorly water-soluble drugs, thereby potentially improving their oral bioavailability.

**Keywords**: Hydrotropic, Solid dispersion, Bioavailability, compatibility, disintegration

**FORMULATION, DEVELOPMENT AND EVALUATION OF TOPICAL NANOEMULGEL CONTAINING ABROCITINIB FOR ATOPIC DERMATITIS TREATMENT**

Hemang Patel, Patel Yukta Ajaykumar, Kantilal B Narkhede, Sachin B. Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
hemangpatel340@gmail.com

This research focuses on the formulation, development, and evaluation of a topical nanoemulgel containing Abrocitinib for the treatment of Atopic Dermatitis (AD). Abrocitinib, a selective JAK1 inhibitor, was incorporated into a nanoemulsion system using Kollisolv GTA as the oil phase, Tween 80 as the surfactant, and Transcutol HP as the co-surfactant, prepared via spontaneous emulsification. The nanoemulsion was optimized using a $3^2$ factorial design, with oil and surfactant-co-surfactant mixture (Smix) concentrations as independent variables, and zeta potential and globule size as dependent responses. The optimized formulation (F7) exhibited a globule size of 102.2 nm and a zeta potential of –24.21 mV, indicating good stability. This nanoemulsion was then incorporated into a Carbopol 940 gel base to form a nanoemulgel. The final formulation demonstrated desirable physicochemical properties, including appropriate pH, spreadability, extrudability, and viscosity. In vitro and ex vivo studies confirmed enhanced drug permeation and sustained release. The nanoemulgel was non-irritating in a HET-CAM test and remained stable over 30 days under accelerated conditions. This study successfully developed a promising topical nanoemulgel of Abrocitinib, offering a effective and patient-friendly treatment option for Atopic Dermatitis.

**PC-217**

**FORMULATION AND DEVELOPMENT OF NASAL GEL CONTAINING UBROGEPANT NANOPARTICLES FOR ENHANCED AND RAPID BRAIN DELIVERY IN THE TREATMENT OF MIGRAINE**

Anil M. Pethe, Prasanna Phutane & Vignesh Mohan
Datta Meghe College of Pharmacy, Datta Meghe Institute of Higher Education & Research Sawangi (Meghe) Wardha, Maharashtra, India

The present study aimed to develop an intranasal gel of Ubrogepant-loaded nanoparticles (NPs) for rapid brain delivery and enhanced therapeutic efficacy in migraine treatment. Ubrogepant NPs were prepared using poly(lactic-co-glycolic acid) (PLGA), polyvinyl alcohol (PVA), and polysorbate 80, and characterized for particle size, entrapment efficiency, morphology, in vitro drug release, and pharmacokinetics using LC-MS. The optimized formulation exhibited a particle size of 183.7 ± 12.9 nm, entrapment efficiency of 80.2 ± 3.8%, polydispersity index (PDI) of 0.170 ± 0.02, and zeta potential of –11.2 ± 2.9 mV. The optimized NPs were incorporated into a thermo-reversible gel prepared by the cold technique using various polymers. The gel was evaluated for viscosity, appearance, pH, gelation, and spreadability, followed by in vitro and ex vivo studies for drug release and permeation. Pharmacokinetic and pharmacodynamic assessments were conducted in Sprague–Dawley rats. The NP-loaded intranasal gel demonstrated significantly improved permeability and drug retention in the nasal mucosa, with higher brain concentrations and faster absorption compared to intranasal NPs or oral Ubrogepant. Sustained brain levels translated into superior efficacy in the nitro-glycerine (NTG)-induced migraine model. Overall, the optimized intranasal gel formulation of Ubrogepant NPs exhibited rapid brain targeting, sustained drug delivery, and enhanced therapeutic outcomes, supporting its potential as an effective strategy for migraine management.

**Keywords**: Ubrogepant, Migraine, Nasal gel, PLGA

**BRIDGING IN VITRO AND IN VIVO: A PERTURBED DISSOLUTION VESSEL APPROACH FOR ENTERIC-COATED DICLOFENAC SODIUM TABLETS**

Bagyalakshmi J, Sujan Adithyan T, Balaji R
Department of Pharmaceutics, Sri ramakrishna Institute of Paramedical Sciences, College of Pharmacy, Coimbatore, Tamil Nadu, India – 641 044.
sujanthirumurugan@gmail.com

Dissolution testing remains a critical formulation assessment tool in pharmaceutical development, providing insights into drug release kinetics and their potential in vivo performance. Vessel design significantly influences dissolution outcomes, as hydrodynamic conditions directly affect disintegration and drug release. Although compendial dissolution vessels are standardized and widely accepted, they fail to replicate the complex gastric environment, where contractions and mucosal rugae strongly modulate dosage form behavior. This limitation often contributes to disparities between in vitro and in vivo results. In the present study, the compendial vessel of the dissolution apparatus (LABINDIA) was modified by lining its inner surface with aluminum foil engineered to mimic gastric rugae, thereby creating a perturbed hydrodynamic environment. Enteric-coated diclofenac sodium tablets(50 mg) were selected as the model formulation, and dissolution testing was conducted in both standard (DS-CV) and perturbed vessels (DS-PV) under identical conditions. Experiments were carried out at 37 °C and pH 7.5 phosphate buffer to simulate intestinal conditions. Samples were collected at 15, 30, 60, and 120 minutes, and drug release was quantified using a UV–VIS Double Beam Spectrophotometer (2202 TS). Results demonstrated distinct alterations in drug release profiles within the perturbed vessel compared to the conventional setup. Specifically, the perturbed vessel exhibited a lower absorbance rate at 274 nm than the compendial vessel, indicating reduced drug release under rugae-like hydrodynamic conditions. These findings emphasize the importance of physiologically relevant vessel modifications in enhancing the predictive power of dissolution studies. By bridging the gap between standardized in vitro methods and actual gastric physiology, such approaches provide a more accurate framework for evaluating oral drug delivery systems.

The present study aimed to investigate the individual and combined effects of β-cyclodextrin (βCD) and surfactants (Kolliphor HS15 and Pluronic F127) on the solubility and dissolution of valsartan through a $2^2$

ISBN: 978-81-980623-8-3

factorial design, and to evaluate the feasibility of formulating rapidly dissolving tablets using drugCDsurfactant complexes. Solubility studies revealed that βCD (5 mM) enhanced valsartan solubility by 4.35-fold, while Kolliphor HS15 (2%) produced a remarkable 30.37-fold increase. The combination of βCD (5 mM) and Kolliphor HS15 (2%) demonstrated a synergistic effect, resulting in a 54.43-fold improvement in solubility. Similarly, dissolution studies confirmed that both individual and combined systems significantly enhanced valsartan release ($P < 0.01$). Drug–CD and DrugCDsurfactant complexes consistently showed faster and higher dissolution compared to pure valsartan, with βCD–Kolliphor HS15 and βCDPluronic F127 combinations providing maximum dissolution increases of 31.13% and 24.07%, respectively.Factorial ANOVA results confirmed that both the main and interaction effects of βCD and surfactants significantly contributed to improved dissolution ($P < 0.01$). To validate these findings in a dosage form, 40 mg valsartan tablets were prepared by wet granulation using Drug–CD, DrugKolliphor HS15, and DrugCDKolliphor HS15 systems. Among these, tablets containing DrugCDKolliphor HS15 complexes showed superior dissolution performance, which was retained during stability testing, indicating robustness of the formulation.Overall, the study demonstrates that combining βCD with Kolliphor HS15 is a promising strategy to enhance valsartan solubility, dissolution, and potentially bioavailability, enabling the development of fast-dissolving tablet formulations.

## DEVELOPMENT AND EVALUATION OF A NATURAL ANTIFUNGAL SOAP ENRICHED WITH MEDICINAL PLANT EXTRACTS

Artalakota Divya, Alekkhya Veeramaneni & Magharla Dasaratha Dhanaraju
Department of Pharmacy, GIET School of Pharmacy, Rajahmundry, Andhra Pradesh 533296, India
divyaaratlakota@gmail.com

The growing resistance of fungal pathogens and the adverse effects of synthetic antifungal agents highlight the need for safe, natural alternatives in personal hygiene products. This study focuses on the development of a natural antifungal soap formulated with plant extracts of Azadirachta indica (neem), Aegle marmelos (bael), Cuminum cyminum (cumin), and Foeniculum vulgare (fennel). These botanicals were selected for their well-documented antimicrobial, antifungal, antioxidant, and skin-soothing properties. The soap base was enriched with aqueous and ethanolic extracts, ensuring the preservation of phytoconstituents such as azadirachtin, marmelosin, cuminaldehyde, and anethole. Preliminary evaluations demonstrated significant antifungal activity against common dermatophytes and Candida species, along with favourable physicochemical characteristics including pH balance, stability, and lathering capacity. The synergistic action of these extracts not only inhibits fungal growth but also promotes skin health by reducing inflammation and preventing secondary infections. The formulated soap represents a sustainable, plant-based, and skin-friendly hygiene product that can serve as a natural alternative to conventional antifungal soaps.

**Keywords:** Azadirachta indica, antifungal soap, antifungal agents, antioxidant

## PHARMACEUTICAL CHARACTERIZATION OF TOPICAL ERYTHROMYCIN NANOEMULGEL FOR ACNE VULGARIS

Saarumathi B, Kanitha Deepika S, Senthil Rajan D, Shivani K
Department of Pharmaceutics, PGP College of Pharmaceutical Science and Research Institute, Namakkal, Tamil Nadu, India.
saaruma5787@gmail.com

The main objective of the investigation is to formulate nanoemulsion in gel formulation of Erythromycin in order to overcome the drawbacks associated with the other dosage forms and in order to improve the overall efficacy of the drug. The present work aimed to develop nanoemulgel of Erythromycin for improving its efficacy, stability, and permeability for the treatment of Acne Vulgaris. The aim of this work was to develop an emulgel formulation of Erythromycin, a hydrophobic drug, using Carbopol 934 as gelling agent and Olive oil as penetration enhancer. The influence of gelling agent and penetration enhancers was investigated. The rheological studies, In vitro release, stability studies, thermodynamic stability studies of the prepared nanoemulgels were also evaluated. The prepared nanoemulgels were placed in tightly closed glass vials and stored at ambient temperature. These drug-loaded formulations were subjected to accelerated, thermodynamic stability studies like centrifugation stress, heating cooling stress and freeze-thawing stress, appearance, percent transmittance, refractive index, electrical conductivity. In conclusion, nanoemulsion of Erythromycin gel was developed to a satisfactory level in terms of physical stability tests, appearance, refractive index, Electrical conductivity, lower surfactant concentration. The present study endorsed nanoemulgel of erythromycin to be a promising choice over conventional formulations for the treatment of Acne Vulgaris.

**Keywords:** Nanoemulgel, Erythromycin, Acne Vulgaris, Carbopol 934.

## FORMULATION AND DEVELOPMENT OF TAPINAROF LOADED TRANSETHOSOMAL GEL FOR TREATMENT IN PLAQUE PSORIASIS

Samrudhi Patil and Ramdas Dolas
Sandip University, Nasik
Samrudhipatil52@gmail.com

Objective: This study aimed to develop and optimize tapinarof-loaded transethosomes using Box-Behnken design for improved drug delivery in plaque psoriasis treatment. Methods: Transethosomes were prepared using thin film hydration method followed by probe sonication. Box-Behnken design with 17 experimental runs was employed to optimize formulation parameters. Independent variables included Ceramide NP concentration (2-4% w/v), sodium deoxycholate concentration (0.5-1.5% w/v), and ethanol concentration (10-20% v/v). Dependent variables were particle size and entrapment efficiency. Formulations were characterized for particle size, polydispersity index, zeta potential, and entrapment efficiency using dynamic light scattering and UV-spectrophotometry. Results: The optimized transethosomal formulations demonstrated particle sizes ranging from 112-287 nm with polydispersity index values below 0.3, indicating uniform size distribution. Zeta potential measurements showed values between -32 to -45 mV, confirming excellent physical stability. Entrapment efficiency varied from 72.4% to 89.6% across different formulations. The Box-Behnken model revealed that ceramide NP concentration significantly influenced particle size, while ethanol concentration primarily affected entrapment efficiency. The optimized formulation achieved a particle size of 125±3.2 nm with 87.3±2.1% entrapment efficiency. Conclusion: The developed tapinarof-loaded transethosomes represent a promising delivery system for enhanced topical treatment of plaque psoriasis. The Box-Behnken design successfully optimized formulation parameters, resulting in stable nano-vesicular carriers suitable for transdermal drug delivery in psoriasis management.

**Keywords:** Tapinarof, transethosomes, Box-Behnken design, plaque psoriasis, nano-vesicles

## HERBAL NANOPARTICLES FOR WOUND HEALING: ADVANCES IN DEVELOPMENT, CHARACTERIZATION, AND THERAPEUTIC APPLICATIONS

Rohit Kamboj, and Kumar Guarve
Guru Gobind Singh College of Pharmacy, Yamunanagar, 135001, Haryana, India
rkamboj538@gmail.com

Wound healing is a complex and dynamic process involving hemostasis, inflammation, proliferation, and tissue remodeling. Conventional therapies often face limitations such as poor bioavailability, rapid degradation of active agents, and risk of infection. Herbal medicines, enriched with phytochemicals possessing anti-inflammatory, antioxidant, antimicrobial, and angiogenic properties, have shown remarkable potential in wound management. However, their therapeutic efficacy is frequently hampered by poor solubility, instability, and limited permeability. Nanotechnology-based approaches offer promising solutions to these challenges by enabling the development of herbal nanoparticles with improved stability, controlled release, and enhanced skin penetration. This review highlights recent advances in the formulation and characterization of herbal nanoparticles for wound

ISBN: 978-81-980623-8-3

healing applications. Key aspects include preparation techniques, physicochemical characterization, and evaluation of biological activity through in vitro and in vivo studies. Furthermore, therapeutic mechanisms such as modulation of oxidative stress, stimulation of collagen synthesis, and acceleration of epithelialization are discussed. The article also outlines emerging trends, clinical translation challenges, and future perspectives in integrating herbal nanomedicine into wound care. Overall, herbal nanoparticles represent a novel and effective strategy to overcome the shortcomings of conventional wound healing therapies.

**Keywords**: Herbal Nanoparticles, Nanomedicine, Drug Delivery, Antioxidant, Skin Repair, Tissue Regeneration, Anti-Inflammatory.

## SYNTHESIS, CHARACTERIZATION, AND ANTIBACTERIAL EVALUATION OF TRIMETHOPRIM ZINC OXIDE NANOPARTICLES FOR ENHANCED ACTIVITY AGAINST DRUG-RESISTANT ESCHERICHIA COLI AND BIOFILM-ASSOCIATED UTIS

Chandana Nagaraju, Selvakumar muruganantham
Department of pharmaceutics, Vivekanandha Pharmacy College for Women, Sankari, Salem – 63637303. Tamil Nadu, India
vnchandana841@gmail.com

The emergence of antibiotic-resistant forms of Escherichia coli, the primary cause of urinary tract infections (UTIs), presents an increasing treatment challenge. A promising strategy to improve the effectiveness and distribution of antibiotics is nanotechnology. In order to increase medication solubility and therapeutic potential, trimethoprim-loaded zinc oxide nanoparticles (TZnONPs) were effectively created in this work employing the solvent evaporation technique. With a particle size of 418.61 ± 7.66 nm, a zeta potential of -25.47 ± 0.07 mV, a large drug content (93.67 ± 1.05 mg), and an exceptional entrapment efficiency (96.49 ± 0.81%), TZnONPs-1 stood out as the best formulation among the others. The lack of chemical interactions between the medication and excipients was confirmed by FTIR and DSC characterization, whereas XRD showed partial amorphization, which improved solubility. SEM investigation revealed spherically distributed nanoparticles.In vitro drug release experiments showed that it outperformed pure trimethoprim (29.48 ± 0.81%) by having a sustained release profile of 93.49 ± 0.81% over 360 minutes. With a greater zone of inhibition (3.3 ± 0.37 cm) against E. coli than ciprofloxacin (2.2 ± 0.47 cm), TZnONPs-1 also demonstrated improved antibacterial activity. ZnO-NPs' strong antibiofilm action on urinary catheter surfaces was further validated by biofilm inhibition tests, which showed a substantial decrease in both biofilm mass and viable bacterial count. The biocompatibility of ZnO-NPs was confirmed by the hemolysis assay, which demonstrated a protective role against e. coli-induced RBC lysis and no hemolytic effect. This study identifies TZnONPs-1 as a potential nanocarrier system for the efficient treatment of UTIs, particularly those caused by biofilm-associated infections and drug-resistant microorganisms.

**Keywords:** Urinary tract infection, Trimethoprim, Zinc oxide nanoparticles, Antibacterial activity, Escherichia coli

## DEVELOPMENT AND CHARACTERIZATION OF LULICONAZOLE NANOPARTICLE LOADED NAIL LACQUER FOR TREATMENT OF ONYCHOMYCOSIS

Pandya Aum Divyeshbhai, Shinde Siddhi Suhas, Anuradha P. Prajapati, Sachin Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
aumpandya200@gmail.com

The focus of this work is in developing and assessing a luliconazole-containing nanoparticle embedded nail lacquer for treating onychomycosis. The Preformulation studies conducted using FTIR and UV analysis confirmed compatibility of the drug and excipients. Polymeric nanoparticles were synthesized using the solvent evaporation method and optimization was carried out using a $3^2$ factorial design where polymer and surfactant concentrations were independent factors and particle size, entrapment efficiency, and polydispersity index (PDI) were the response variables. The optimized formula provided a particle size of 120.12 nm, zeta potential 28 mV, PDI of 0.137, and an entrapment efficiency of 85%. The nanoparticles were incorporated into a lacquer and to evaluate the formulation, the following were tested: drying time, water resistance, viscosity, non-volatile content, and in vitro drug release. One month stability studies were carried out to assure the formulation was intact. The results suggest that the nanoparticulate nail lacquer is a stable and user-friendly formulation which allows for sustained transungual drug delivery and has enhanced antifungal efficacy for the treatment of onychomycosis.

**Keywords:** Onychomycosis, nanoparticles, luliconazole, transungual, nail lacquer

**PC-226**

## A COMBINATION OF TREATED EGG WASTE AND ALLANTOIN FOR MANAGEMENT OF HYPERPIGMENTATION: QBD APPROACH FOR FORMULATION DEVELOPMENT

Jeevajothi B, R. Aishwarya Reddy , Ashwin Ravichandran
Department of Pharmaceutics, Acharya and B M Reddy College of Pharmacy, Soldevanahalli, Bangalore, Karnataka, India-560107
jeevajothib27@gmail.com

This study explored the formulation and evaluation of a gel-based treatment for hyperpigmentation, with a focus on inhibiting Tyrosinase (TYR) and its related proteins, TYRP1 and TYRP2, which are involved in melanin biosynthesis. In-silico docking studies were performed using the Pyrx virtual screening tool to identify potential drug candidates with high binding affinity for the target proteins. The selected compounds were analysed for their ability to inhibit melanin production, a key factor in hyperpigmentation disorders. Preformulation studies included developing calibration curves, FTIR compatibility analysis, and extracting bioactive compounds from eggshell membrane (ESM) via enzymatic hydrolysis. These results guided the formulation of a gel containing 1% Allantoin and 10% ESM, stabilized with Carbopol and other excipients. To optimize the gel's formulation, response surface methodology (RSM) based on a central composite design (CCD) was used to adjust parameters such as polymer concentration, viscosity modifier, and temperature. The optimized gel demonstrated desirable characteristics, including optimal viscosity, drug permeation, and pH. Evaluation tests, including thermodynamic stability studies, viscosity, spreadability, and in-vitro permeation using Franz diffusion cells, showed that the gel was stable under freeze-thaw cycles and exhibited favorable drug release profiles. Further characterization indicated good texture properties such as cohesiveness and adhesiveness, essential for topical application. Cell viability assays using B16-F10 murine melanoma cells showed promising effects on cell growth inhibition. Overall, the developed gel formulation shows potential as an effective treatment for hyperpigmentation, addressing conditions like melasma and age spots.

**Keywords:** Hyperpigmentation, melanin, tyrosinase inhibition, allantoin, egg shell membrane.

**PC-227**

## FORMULATION AND EVALUATION OF LINAGLIPTINE FAST DISSOLVING BUCCAL FILMS USING DESIGN EXPERT

G.Niharika, Saritha Madepathi
Vignan Institute Of Pharmaceutical Technology.
chsaritha19752@gmail.com

Linagliptin is used for treating type-II diabetes. It is a BCS-III drug that has high solubility and low permeability. The aim of the present study is to formulate and evaluate buccal films to release the drug effectively and efficiently, avoid first pass metabolism, improved absorption and improve patience compliance and optimization of Buccal films prepared by solvent casting method employing DOE approach. Design of experiments (DOE) was used, taking HPMC, SSG and CCS as independent variables, disintegration time and percentage drug released as dependent variables (responses). Seventeen runs were designed by DOE software. The films were prepared by solvent casting method. All the films were evaluated for film thickness, % drug content, moisture loss, folding endurance, disintegration time and %drug released. Eventually after inserting the response data in DOE table the software suggested an optimized formulation was given by the software which is prepared and evaluated.

**Keywords**: linagliptine, buccal films, solvent casting, disintegration time, design expert.

**PREPARATION AND CHARACTERIZATION OF DRUG-LOADED MESOPOROUS SILICA NANOPARTICLES TO TREAT CANCER-INDUCED EMESIS IN WISTAR ALBINO RATS**

Biki Rilum, Venkatesh Dinnekere Puttegowda, Abhishek R, Manjunatha Panduranga Mudagal
Department of Pharmaceutics, Acharya & B M Reddy College of Pharmacy,Bangalore, Karnataka - 560107
abhishekrabhi03@gmail.com

The present research focused on the preparation and characterization of mesoporous silica nanoparticles (MSNs) loaded with ondansetron hydrochloride (OND.HCl) for managing chemotherapy-induced nausea and vomiting. MSNs were prepared via the solvent immersion (Disulpho method) at varying drug-to-carrier ratios, stirring speed, and time. Preliminary studies included drug identification and solubility analysis using UV and FTIR, confirming drug compatibility with MSNs. Physicochemical characterizations involved particle size, zeta potential, SEM, and BET analysis. In vitro release was evaluated in pH 1.2 medium, while In vivo antiemetic efficacy was assessed in rats. Among formulations, MCM-41 (F1) and SBA-15 (F2) demonstrated the highest loading efficiencies (97.0±2.19% and 95.7±1.21%, respectively). The loaded MSNs showed mean particle sizes ≤ 725.5 nm with spherical morphology confirmed by SEM (≤ 450–570 nm). BET analysis revealed high surface areas (999.43–1472.22 $m^2/g$), pore volumes (1.073–1.141 cc/g), and pore sizes (2.495–4.827 nm). In vivo results confirmed superior antiemetic activity in rats treated with drug-loaded MSNs. Stability testing demonstrated satisfactory performance at 40±2°C/75±5% RH for 3 months. Overall, OND.HCl-loaded MSNs were successfully developed with high drug loading, controlled release, better stability, and enhanced antiemetic efficacy using minimal excipients.

**Keywords:** Mesoporous silica nanoparticles, Ondansetron HCl, MCM-41, SBA-15, Cancer

**FORMULATION AND EVALUATION OF NANOSTRUCTURED LIPID CARRIER SYSTEM FOR BRAIN DRUG DELIVERY**

J. Joysa Ruby, E.Sasikala Sanal Prasad venkadesh DP
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Soldevanahalli, Road Bengaluru, Karnataka, India-560107
Sasikalakala2001@gmail.com

Alzheimer's disease is a progressive, incurable neurodegenerative disorder marked by the degeneration of nerve cells including tau protein-based neurofibrillary tangles and amyloid-beta (Aβ) plaques. The prevalence is expected to reach 131.5 million by 2050, with cases steadily increasing since 2015. Although the precise cause remains unclear, multiple pathological factors contribute to its onset and progression. The present research focuses on the development of Donepezil-loaded Nano Lipid Carrier (NLC) and in vitro evaluation. NLCs were prepared by high-pressure homogenization followed by bath sonication, using varying concentrations of GMS (100–200 mg w/v), oleic acid (2–4 ml v/v), and Poloxamer (100–200 mg w/v). Preformulation studies, including FT-IR for drug–excipient compatibility, were performed. Characterization involved, particle size, PDI, zeta potential, entrapment efficiency (EE), drug loading and SEM. In vitro drug release, cell line studies, and stability assessments were also conducted. FT-IR confirmed drug–excipient compatibility. SEM revealed spherical particles with morphology. Optimized batch (F7) showed particle size 272 nm, PDI 0.493, zeta potential –25.2 mV, entrapment efficiency 72.60%, and drug loading 23.3±2.6%. In vitro studies for 48 h demonstrated and found 81.70% cumulative release, following sustained kinetics ($R^2$ = 0.9163). Cell line studies indicated higher cell viability for NLC formulation compared to plain drug solution. Donepezil-loaded NLCs demonstrated suitable particle size, stability, and sustained release, making them promising for brain delivery via the nasal route in Alzheimer's management.

**Keywords:** Alzheimer's, Nano lipid carriers, GMS, Donepezil HCl, High-pressure homogenization.

**PC-230**

**FORMULATION AND ANTIMICROBIAL INVESTIGATION OF IXORA COCCINEA PHYTOSOME-LOADED TOPICAL GEL**

R. Jasmin Sajini, C. Vinodhini, D. Chamundeeswari
Department of Pharmaceutical Chemistry, Sri Ramachandra Faculty of Pharmacy, SRIHER, Porur, Chennai-600116.

Various species of Ixora are used in Ayurveda, Folk, Siddha, and Unani systems of medicine for treating dysentery, healing ulcers, and exhibiting anti-tumor activity. The aim of the present study was to prepare a phytosome-loaded topical gel from the ethyl acetate fraction of Ixora coccinea leaves and to evaluate its in vitro antimicrobial efficacy.Phytosomes were prepared using the plant extract (ICLEA) with different ratios of phosphatidylcholine (1:0.5, 1:1.0, 1:1.5; PLE1–PLE3) by the solvent evaporation method. The phytosomes were evaluated for particle size, SEM analysis, IR, drug content, and drug entrapment efficiency. The optimized phytosome-loaded extract (PLE1) showed a particle size of 245.30 ± 0.01 nm, and vesicle formation was confirmed by SEM analysis.The optimized phytosome (PLE1) was incorporated into carbopol-based topical gel formulations (PLTG2–PLTG4). Additionally, a conventional extract-loaded topical gel (ELTG) was prepared and compared with the phytosome-loaded gels. The formulations were evaluated for parameters such as pH, homogeneity, grittiness, spreadability, viscosity, gel strength, drug content, and in vitro diffusion studies.Among the formulations, PLTG2 showed optimal evaluation parameters and superior drug release performance. Stability studies indicated that the optimized topical gel remained stable, with no significant changes in any parameter when stored at 25 °C ± 2 °C/60 % RH ± 5 % RH and 40 °C ± 2 °C/75 % RH ± 5 % RH. Antimicrobial studies demonstrated that PLTG2 produced a comparable zone of inhibition with standard drugs. The study confirms that phytosome-loaded topical gel of Ixora coccinea (PLTG2) exhibits better physicochemical properties, sustained drug release, stability, and promising antimicrobial activity compared to conventional extract-loaded gels.

**Keywords**: Phytosome,Ixora, Global Health, Health Care.

**FORMULATION AND EVALUATION OF MICROSPHERES ENCAPSULATING ZIDOVUDINE BY IONIC GELATION AND SOLVENT EVAPORATION TECHNIQUES**

Supritha C, Vasir Ashfaq Ahmed
Department of Pharmaceutics, Ikon Pharmacy College, Bidadi, Ramanagara, Karnataka, India-562109
suprithachinnegowda@gmail.com

The aim of the present study is an attempt to formulate and evaluate microspheres drug delivery of Zidovudine by using Chitosan and Eudragit L100 as a polymer for potentially treating HIV and AIDS related conditions. The formulation F1 to F4 which were prepared by ionic gelation and the formulation F5 to F8 were prepared by solvent evaporation methods by varying the concentration of Chitosan and Eudragit L100 polymer ratios which were significantly affected the in vitro drug release from the prepared formulations. The in vitro drug release studies were carried out by using phosphate buffer pH 7.4. Drug and physical mixture were characterised by FTIR, the result of IR study showed that no interaction between drug and polymers and other formulation parameters of formulated microspheres are evaluated which showed better results. It was concluded that the formed microspheres showed prolonged in vitro drug release. It might contribute better patient compliance while reduce frequency of dosing and by acceptable sustained-release dosage form Zidovudine microspheres promote a fast and effective against the AIDS related conditions. From the, in vitro drug release studies and release kinetics studies it can be concluded that the formulation F4 prepared by ionic gelation method has better potential of sustaining drug release.

**Keywords:** Zidovudine, microspheres, controlled drug delivery, Ionic gelation technique, solvent evaporation method.

**PC-232**

**CHRONO FLOAT: DESIGN AND DEVELOPMENT OF A FLOATING PULSATILE RELEASE SYSTEM FOR DOMPERIDONE**

Subhiksha. V. C, Radhakrishnan. S
Department of pharmaceutics, The Erode College of Pharmacy
The Tamil Nadu Dr M.G.R Medical University
sekarsubhi1@gmail.com

Nausea and vomiting frequently accompany gastrointestinal disorders and various treatments, detracting from patient comfort and adherence.

ISBN: 978-81-980623-8-3

Gastroretentive pulsatile drug delivery systems (GRPDDS) time-controlled release within the stomach, optimizing absorption for drugs with limited absorption windows such as domperidone. To formulate and refine a floating pulsatile release tablet (FPRT) of domperidone that remains buoyant for at least 11 hours, incorporates a 4-hour lag phase, and subsequently discharges the full dose rapidly. Domperidone cores were produced by wet granulation with crospovidone, lactose, citric acid, and sodium bicarbonate. Press-coating employed HPMC K100M, HPMC K4M, and ethyl cellulose combined with sodium bicarbonate to impart floatation and regulate pulsatile release. Five formulations (F1–F5) were optimized using a Design of Experiments framework to target specific lag and buoyancy durations. Evaluations included flow behavior, weight uniformity, hardness, friability, floating lag time, buoyancy duration, swelling index, and in vitro dissolution. FT-IR spectroscopy assessed drug–excipient compatibility, and ANOVA determined the impact of polymer ratios. All batches conformed to pharmacopeial criteria. Formulation F4 demonstrated superior performance: it floated within 4 minutes, sustained buoyancy for 11 hours, exhibited a swelling index of 90.4%, and showed a pulsatile release profile—no drug release during the 4-hour lag followed by complete release within 2 hours. Polymer composition significantly influenced release kinetics. The optimized FPRT (F4) achieved precise lag timing, prolonged gastric retention, and swift post-lag drug delivery, presenting a promising chronotherapeutic approach to enhance domperidone's efficacy and patient compliance.

**Keywords**: Domperidone; Floating pulsatile release; Gastroretentive delivery; Lag time.

**PC-233**

## FORMULATION AND EVALUATION OF METOCLOPRAMIDE CHEWING GUM TO TREAT MOTION SICKNESS

Manisha Kumari Sah, Venkatesh D P, Punya R, Manjunatha P M
Department of Pharmaceutics, Acharya & B M Reddy College of Pharmacy, Bangalore, Karnataka – 560107
Punyagowda199@gmail.com

A medicated chewing gum containing Metoclopramide hydrochloride was developed for the treatment of motion sickness to provide rapid onset of action and improve patient compliance. The formulations were prepared by the conventional method using gum base, glycerine/sorbitol, talc, sugar, colouring and flavouring agents. They were evaluated for physical appearance, weight variation, drug content, stickiness, texture, in vitro drug release, sensory evaluation, and stability. The chewing gums exhibited good organoleptic properties including chewability, taste, softness, and mouthfeel. Among the formulations, F2 showed promising results with 86.94% drug release within 15 minutes, indicating potential for enhanced bioavailability by reducing onset time. Drug release was found to be influenced by formulation factors such as gum base selection and plasticizer proportion. Stability testing conducted for three months at 40 ± 2°C and 75 ± 5% RH confirmed no significant changes in physicochemical characteristics or release profile of F2. Thus, medicated chewing gum of metoclopramide hydrochloride proved effective, stable, and patient-friendly for motion sickness management.

**Keywords:** Medicated chewing gum, Metoclopramide hydrochloride, Motion sickness, Conventional method

## FORMULATION AND DEVELOPMENT OF IMMEDIATE-RELEASE MICROENCAPSULATED VITAMIN B12 LOZENGES FOR DEFICIENCY MANAGEMENT AND WELLNESS SUPPORT

Hiren R Baria, Neha Vadgama, Sachin B Narkhade
Smt.B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
hirexbaria@gmail.com

Vitamin B12 deficiency is an emerging public health issue, and evidence indicates that 50–60% of population, predominantly women of India have below optimal levels. This research involves the formulation of microencapsulated Vitamin B12 lozenges by solvent evaporation technique, each providing 250 µg of Vitamin B12. Microencapsulation is employed to safeguard the vitamin from premature breakdown and enhance its bioavailability, thus helping to maintain and sustain sufficient Vitamin B12 levels in the body. Formulation also features a natural disintegrating agent for immediate release, an antioxidant botanical source for immunological support, a phytonutrient-rich botanical that supplies necessary micronutrients, and a metabolism supporting botanical to maintain digestive health. A natural sweetener, colour and flavour, make the lozenges palatable and improve patient compliance. The product is not only vegetarian but also vegan friendly and classified as a nutraceutical. Ongoing assessment includes hardness, friability, disintegration time, rate of dissolution, and uniformity of content. Preliminary results indicate that the lozenges disintegrate rapidly in the oral cavity, enabling rapid release of Vitamin B12 for efficient absorption. Additional research, including stability testing, antioxidant retention testing, bioavailability modeling, and sensory testing, is underway to ascertain product consistency, long term safety, and user acceptability. This method offers a handy, consumer-oriented solution to Vitamin B12 deficiency. By utilizing advanced microencapsulation technology combined with well chosen botanicals, the lozenges seek to supply a stable, safe, and efficient nutraceutical that supports Vitamin B12 levels and nutritional wellbeing.

**Keywords:** Vitamin B12 deficiency, Lozenges, Microencapsulation, solvent evaporation technique, Nutraceutical.

## MUCOADHESIVE GASTRORETENTIVE FLOATING MICROSPHERES OF LEVOFLOXACIN: A NOVEL APPROACH TO PROLONGED ANTIBIOTIC THERAPY

Sudarsan S M, Radhakrishnan. S
Department of pharmaceutics,The Erode College of Pharmacy,638112, The Tamil Nadu Dr M.G.R Medical University
tis7bsudarsan@gmail.com

Oral drug delivery systems face significant challenges in achieving controlled release, particularly in the gastrointestinal tract where drug absorption can be highly variable and unpredictable. Floating microspheres represent an innovative approach to enhancement of gastric retention and improve bioavailability of therapeutic agents, addressing the limitations of conventional solid oral dosage forms. This study aimed to develop and evaluate levofloxacin-loaded floating microspheres using various polymeric combinations to achieve sustained drug release and enhanced gastric retention for improved therapeutic efficacy. Floating microspheres were prepared using the solvent evaporation method with different polymer combinations including HPMC K4M, HPMC K100M, sodium alginate, and sodium carboxymethyl cellulose. Ten formulations (F1-F10) were developed and evaluated for micromeritic properties, drug entrapment efficiency, buoyancy studies, in-vitro dissolution, particle size analysis, and morphological characterization using scanning electron microscopy. Formulation F7 demonstrated optimal performance with the highest percentage yield (90.12%) and drug entrapment efficiency (88.96%). The microspheres exhibited excellent buoyancy properties with sustained drug release over 12 hours. Particle size analysis revealed an average diameter of 60±3.8µm for F7. FTIR studies confirmed drug-polymer compatibility without chemical interactions. Stability studies showed minimal variation in drug release under various storage conditions. The solvent evaporation method successfully produced levofloxacin-loaded floating microspheres with sustained release capabilities. Formulation F7 emerged as the optimal formulation, demonstrating superior pharmaceutical properties and promising potential for enhanced antibiotic therapy through improved gastric retention and controlled drug delivery.

**Keywords:** Floating microspheres, Levofloxacin, Solvent evaporation.

## FORMULATION AND EVALUATION OF DICLOFENAC SODIUM LOADED TRANSDERMAL PATCH USING CHITOSAN DERIVATIVE

Pallavi W Sawwalakhe, Amruta S Phuse, Prasad R Deshmukh, Dipti B Ruikar
P. R. Pote Patil College of Pharmacy, Amravati, Maharashtra 444603

Transdermal patches represent a non-invasive dosage form that delivers medication directly into the bloodstream, bypassing the significant first-pass metabolism experienced by orally administered drugs. The system was designed as a multi-layered matrix patch to provide a controlled release of the medication. Objective of study to synthesize N- palmitoyl chitosan used as permeation enhancer with controlled released for

ISBN: 978-81-980623-8-3

diclofenac transdermal patch. N-palmitoyl chitosan was prepared by using palmitoyl chloride and characterized by FTIR, DSC and XRD. Diclofenac sod was loaded in macroparticle using N- palmitoyl chitosan and TPP using ionotropic gelation method and was evaluated for drug loading (51.40%). The patches were meticulously prepared using a solvent evaporation technique. This process involved creating a backing membrane with 2% (w/v) polyvinyl alcohol (PVA), film-forming polymers such as HPMC, PVP, and ethyl cellulose, 15% dibutyl phthalate as a plasticizer with macroparticles of diclofenac sod equivalent to 15 mg. Prepared patches were demonstrated excellent physical characteristics, maintaining a uniform shape and exhibiting 100% flatness without any curling or stickiness. The patches were smooth, slightly opaque, and showed good flexibility and mechanical strength. The average drug contents were found to be 0.590 mg/cm² for patch of chitosan macroparticles 1.529 mg/cm² for patch of N-palmitoyl chitosan macroparticles. While In-vitro released study revealed plane diclofenac sod patch released 99.33%, chitosan macroparticle containing patch released 67.06% and N-palmitoyl chitosan macroparticle patch released 45.94% diclofenac within 1 hr. Permeation study revealed about 43.48% diclofenac sod able to penetrated by N-palmitoyl chitosan macroparticles patch while 29.24% by chitosan macroparticle patch. In conclusion, synthesize N-palmitoyl chitosan was evaluated as a promising material for controlled delivery also permeation enhancer for diclofenac sodium in transdermal patch.

**Keywords** - N-palmitoyl Chitosan, Diclofenac Sodium, Controlled Release, Permeation Enhancer

## FORMULATION AND EVALUATION OF MESALAMINE IN-SITU GEL TABLET USING EXTRACTED STARCH AND PECTIN

Dehuti S Fate, Vaishnavi R Shahare, Prasad R Deshmukh, Dipti B Ruikar
P. R. Pote Patil College of Pharmacy, Amravati, Maharashtra 444603

In Situ gel forming tablet represents an innovative approach in oral drug delivery, enhancing the solubility and controlled release of medications. The objectives was to extract, characterize, and evaluated of natural polymers jackfruit seed extracted starch and jackfruit core extracted pectin as In Situ gelling agents and its application in the formulation of In Situ gel of mesalamine oral tablet for targeting colonic drug delivery. These polymers were selected for their biodegradability, mucoadhesive potential, and ability to undergo sol-to-gel transition at physiological pH. Extraction of starch was carried out using aqueous method while extraction of pectin was carried out using dried powder and distilled water and filtered through muslin cloth and characterized using FTIR, confirming the presence of functional groups and pharmacognostic study reveals the presence of chemical constituents (starch and pectin), swelling index study confirms the gelling nature of extracted starch and pectin which confirmed its application as in situ gelling material. A total of four batches of mesalamine in situ gel tablets were formulated by direct compression using the extracted starch and pectin along with xanthan gum, HPMC, microcrystalline cellulose, magnesium stearate and talc. To provide enteric protection and achieve targeted drug release, the tablets were coated with Eudragit L100, ensuring that drug release occurred in response to the intestinal pH. Enteric coated mesalamine tablets were evaluated which exhibited superior characteristic including acceptable thickness(5.68mm), hardness (7.0 kg/cm2), weight variation(784.1±39.07mg), swelling index (589.85% at 120 mins) which shows effective pH-responsive gelation at pH 6.8. The disintegration studies in 0.1N HCl showed the acid uptake of 5.44% that fulfil the criteria of enteric coating. In- Vitro drug release studies were carried out using rotating paddle dissolution test apparatus at 6.8 pH phosphate buffer shows 91.91% drug release in 6hours which confirmed that the formulation resist disintegration in gastric conditions and formed a stable gel matrix in the intestinal environment, enabling sustained drug release. FTIR studies confirmed no significant chemical interactions between mesalamine and the excipients, establishing formulation stability and compatibility. In conclusion, the study successfully demonstrates the potential of jackfruit seed extracted starch and core extracted pectin as effective, eco-friendly In Situ gelling agents.

**Keywords**- Jackfruit, Starch, Pectin, In Situ, Mesalamine, Controlled Release.

## DESIGN AND OPTIMIZATION OF A GASTRO-RETENTIVE MODIFIED RELEASE FORMULATION OF CIMETIDINE USING BIODEGRADABLE POLYMER

Patel Hemangikumari narendrabhai, Dr. Himanshu K. solanki, Vedant R. Patel
Dept. of Pharmaceutics, SSR College of Pharmacy (Permanently Affiliated to Savitribai Phule Pune University), Sayli-Silvassa, Silvassa-396230, Union Territory of Dadra Nagar Haveli and Daman Diu, India.
patelhemanginarendra@gmail.com

The objective of this study was to design and optimize Cimetidine-loaded sodium alginate beads as an oral multiparticulate formulation exhibiting floating and mucoadhesive characteristics. Beads were prepared using the ionotropic gelation method with sodium alginate as the polymer and sodium bicarbonate as the gas-generating floating agent. A $3^2$ full factorial design was applied to investigate the effects of sodium alginate ($X_1$) and sodium bicarbonate ($X_2$) on formulation responses: drug entrapment efficiency ($Y_1$, %DEE), drug release at 720 min ($Y_2$, $Q_{720}$ min), floating lag time ($Y_3$, FLT), total floating time ($Y_4$, TFT), and percentage mucoadhesion ($Y_5$).The optimized batch, containing 1133 mg of sodium alginate and 217 mg of sodium bicarbonate, demonstrated high %DEE (86.81 ± 1.81%), minimal FLT (135.33 ± 2.52 sec), extended floating duration (10.31 ± 0.18 hrs), and sustained drug release (~96.79 ± 0.46% at 12 hrs). Drug release followed the Korsmeyer-Peppas model, with a release exponent n = 0.6653, indicating non-Fickian (anomalous) transport, suggestive of a mechanism involving both diffusion and polymer matrix relaxation. FTIR analysis confirmed no significant chemical interactions between Cimetidine and the formulation excipients. SEM images revealed spherical, rough-surfaced beads with localized drug crystals, potentially contributing to an initial burst release. The formulation demonstrated good short-term stability under both ambient and refrigerated conditions. Overall, the optimized formulation provides a promising platform for improved gastric retention and sustained delivery of Cimetidine, potentially reducing dosing frequency and enhancing therapeutic outcomes.

**Keywords:** Cimetidine, gastro-retentive drug delivery system (GRDDS), beads, ionotropic gelation, multiparticulate drug delivery, floating-mucoadhesive systems, $3^2$ factorial design optimization, Korsmeyer-Peppas kinetic model.

## DEVELOPMENT AND EVALUATION OF CHITOSAN/SILK/CARBONATED HYDROXYAPATITE SCAFFOLDS FOR BONE REGENERATING APPLICATION

Trupti Dhurde, Patil Bhuvaneshwari, Ravindra V Badhe
Department of Pharmaceutical Chemistry, Marathwada Mitra Mandal's College of Pharmacy, Pune-411033 (M.S.), India
truptidhurde5@gmail.com

Bone defects caused by trauma, tumors, congenital anomalies present challenges in clinical management. Traditional treatments like autografts, allografts, and xenografts face limitations, including donor site morbidity, immune rejection, and poor integration. Recent advances in bone tissue engineering offer promising alternatives by leveraging biomaterials, growth factors, and cells to create biocompatible scaffolds that mimic natural bone structures. Study focuses on development and evaluation of composite scaffolds made from chitosan, silk fibroin, and carbonated hydroxyapatite (CHA) for regenerative bone applications. Scaffolds fabricated using freeze-drying techniques and characterized for porosity, swelling, mechanical properties, degradation rates. Analytical methods, including FTIR, DSC, XRD, confirmed structural integrity and material compatibility. In vitro studies demonstrated excellent biocompatibility, with enhanced cell proliferation and angiogenesis observed in scaffolds containing growth factors. Biodegradation tests indicated controlled degradation rates suitable for tissue regeneration. The results highlight synergistic effects of chitosan, silk and CHA in creating a scaffold that supports cell growth, promotes vascularization, and facilitates bone tissue regeneration. Study provides foundation for advancing bone graft substitutes, offering scalable and effective solution for treating critical-sized bone defects.

**Key Words:** scaffolds, chitosan, silk fibroin, carbonated hydroxyapatite

**FORMULATION, CHARACTERIZATION AND IN-VITRO COMPARISON STUDIES OF CHLORZOXAZONE MICROSPHERES BY USING NATURAL AND SYNTHETIC POLYMERS**

Tamilselvan N, Rameena P, Balamugunthan S, Akash L
Department of Pharmaceutics, PGP College of Pharmaceutical Science and Research Institute, Namakkal, Tamil Nadu, India-637 207
ntamilselvan292003@gmail.com

Formulating, analysing, and comparing chlorzoxazone microsphere in vitro dissolution data was the goal of this study. One treatment for spasticity is chlorzoxazone, a skeletal muscle relaxant. Chlorzoxazone has a half-life of one to two hours. For this kind of medicinal candidate, microspheres work well as a drug delivery mechanism. Because of the need to develop an appropriate dosage form that allows for both easy dosing and prolonged drug release, the ionic gelation process was used to make microspheres. To ensure that the FT-IR approach would not be used to detect drug-polymer interactions, pre-formulation experiments were conducted. In this investigation, sodium alginate and ethyl cellulose were used as natural and synthetic polymers, respectively. Surface morphology, micromeritics characteristics, entrapment efficiency, and in vitro drug release were evaluated for all four batches of microspheres (E1–E4 and S1–S4). The best formulation for the preparation of a novel chlorzoxazone drug delivery system was determined to be microspheres made of ethyl cellulose (E3) polymer. These microspheres exhibited the highest drug content (85.7%), entrapment efficiency (91.5%), percentage yield (77.3%), and in vitro drug release (88.55%) for 16 hours.

**Keywords:** Chlorzoxazone, Skeletal muscle relaxant, Ethyl cellulose, Sodium alginate.

**DUAL-DRUG ELECTROSPUN NANOFIBER TRANSDERMAL SYSTEM FOR ENHANCED BIOAVAILABILITY IN TYPE 2 DIABETES MELLITUS**

Yashraj Mahendrasinh Solanki
Department of Pharmaceutical, SSR College Of Pharmacy, Sayli Road, Silvassa-396230
yashrajsolanki4545@gmail.com

Type 2 Diabetes Mellitus (T2DM) is a chronic metabolic disorder often requiring combination therapy with Metformin hydrochloride (MH) and Sitagliptin phosphate (SP). However, oral administration of this combination is associated with gastrointestinal complications, poor patient compliance, and reduced bioavailability. In this study, a dual-drug electrospun nanofiber (NF)-based transdermal delivery system was developed for the first time to address these limitations. Electrospun nanofibers were fabricated using individual and blended polymers to optimize fiber morphology, mechanical strength, and drug release behavior. Characterization by scanning electron microscopy confirmed bead-free morphology with uniform distribution, while Fourier-transform infrared spectroscopy and differential scanning calorimetry verified drug–polymer compatibility and amorphous drug dispersion. The optimized nanofibers exhibited tensile strength of 2.4 ± 0.2 MPa, ensuring mechanical stability for transdermal application. In vitro diffusion studies using Franz cells showed sustained release of approximately 80% MH and 75% SP over 24 hours. Pharmacokinetic evaluation in animal models demonstrated enhanced systemic absorption, with a 1.8-fold increase in relative bioavailability compared to oral dosing ($p < 0.05$), along with prolonged plasma drug levels and reduced fluctuations. These findings indicate that the electrospun dual-drug nanofiber system enables controlled release, improves bioavailability, and minimizes gastrointestinal side effects, offering a promising strategy for long-term T2DM therapy. This innovative formulation has potential to enhance therapeutic efficacy and patient adherence through a convenient and effective transdermal drug delivery platform.

**Keywords:** Electrospun nanofibers, Transdermal delivery, Metformin hydrochloride, Sitagliptin phosphate, Type 2 Diabetes Mellitus

**INTRANASAL CHITOSAN NANOPARTICLES OF VERICIGUAT FOR ENHANCED BRAIN DELIVERY IN ALZHEIMER'S DISEASE**

Kruti Mahesbhai
Department of pharmacology, SSR College of pharmacy, Sayli Road Silvassa 396230

Alzheimer's disease (AD) is a progressive neurodegenerative disorder associated with memory impairment and cognitive decline, with limited therapeutic options. Vericiguat, a soluble guanylate cyclase (sGC) stimulator approved for cardiovascular disorders, has shown potential to improve neuronal signaling through the cyclic guanosine monophosphate (cGMP) pathway. However, poor brain bioavailability through systemic administration restricts its therapeutic application in AD. To address this challenge, Vericiguat-loaded chitosan nanoparticles were developed for intranasal delivery to bypass the blood–brain barrier and enhance brain targeting. Nanoparticles were prepared by spray-drying and evaluated for particle size, surface charge, and encapsulation efficiency. The optimized formulation exhibited a mean particle size of 155 ± 8 nm, zeta potential of +26.4 mV, and encapsulation efficiency of 82.7%, demonstrating stability and mucoadhesive properties favorable for nasal administration. Molecular docking confirmed strong binding affinity of Vericiguat with the sGC receptor, supporting its therapeutic relevance in AD. In vivo studies in AD-induced rodent models using behavioral tests such as novel object recognition and Morris water maze showed significant improvements in learning and memory in animals treated with intranasal Vericiguat nanoparticles compared to free drug ($p < 0.01$). These findings confirmed enhanced brain uptake and superior therapeutic efficacy. Overall, intranasal chitosan nanoparticles of Vericiguat represent a promising drug delivery approach for improving cognitive outcomes in AD and highlight the potential of repurposing cardiovascular drugs for neurodegenerative disorders.

**Keywords:** Alzheimer's disease, Vericiguat, Chitosan nanoparticles, Intranasal delivery, Brain targeting

**FORMULATION AND EVALUATION OF NANO-GEL BY USING DIFFERENT CHALCONE FOR THEIR ENHANCED ANTI-INFLAMMATORY AND ANALGESIC ACTIVITIES**

Silawat Fatema Abdul Rauf, Pathan Muzakkir Ahmed, Dr. Shaikh Gazi, Dr. Mohammad Rayees
Dep. Of pharmaceutics, RP College of pharmacy, Dharashiv, MH 413501
Dep. Of pharmaceutical chemistry, RP College of pharmacy, Dharashiv, MH 413501

Pro-inflammatory cytokines like TNF-α and IL-1β induce chronic inflammation, oxidative stress, and progressive joint deterioration, which are hallmarks of arthritis disorders, especially rheumatoid arthritis, which continue to be a major cause of disability globally. Nonsteroidal anti-inflammatory medicines (NSAIDs) and other conventional therapy relieve symptoms but face challenges such as limited bioavailability , poor therapeutic targeting and undesirable systemetic side effect , they are frequently constrained by immunological, hormonal, and gastrointestinal side effects emerging nanotechnology based strategies are reshaping the therapeutic landscape , with nano emulsion offering particularly versatile platform ,to overcome these drawbacks, a chalcone oil–based oil-in-water (O/W) nanoemulsion gel was developed as a novel topical anti-arthritic formulation. The nanoemulsion, consisting of kinetically stable droplets in the 10–200 nm range, enhanced dermal penetration, improved solubility, and offered sustained release of bioactive constituents with capsicum oils or semisynthetic chalcone. Preclinical evaluation in models of arthritis showed excellent symptom management and a notable reduction in oxidative stress and inflammatory markers without causing systemic harm. These results highlight chalcone nanoemulsion gel as a promising, patient-friendly alternative for arthritis management, synergizing the therapeutic potential of natural phytoconstituents with the advantages of nanotechnology-driven drug delivery.

## DESIGN AND IN-VITRO EVALUATION OF BUCCOADHESIVE TABLETS OF OLMESARTAN MEDOXOMIL

Varsani Dimpal, Venkatesh Dinnekere Puttegowda, Mamatha Sree J, Manjunatha Panduranga Mudagal
Department of pharmaceutics, Acharya & BM Reddy College of Pharmacy, Soladevanahalli, Achit nagar (Post), Acharya Sarvepalli Radhakrishnan Road, Bengaluru-560107, Karnataka, India.
sreereddy9111@gmail.com

Mucoadhesive buccal tablets of Olmesartan medoxomil were formulated using different bioadhesive polymers, namely Carbopol 934P, HPMC K4M, Sodium carboxymethyl cellulose, and Hydroxyethyl cellulose, in varying ratios (1:1, 1:2, and 1:3).The backing layer consisted of ethyl cellulose, an impermeable substance. Olmesartan medoxomil was developed in nine different formulations utilizing the direct compression process.To increase the solubility of Olmesartan medoxomil, a solid dispersion was used with various ratios of Poloxamer F407 polymer (1:1, 1:2, and 1:3). The produced tablets were tested for erosion, surface pH, bioadhesive characteristics, in vitro drug release, and drug diffusion. The swelling index was found to be proportional to the Carbopol 934P and HPMC K4M contents.The surface pH of all formulations ranged between 5-7, indicating their suitability for buccal application without causing irritation.The tablets with 1:2 ratios of carbopol 934P:HPMC K4M showed the highest percentage of drug release and diffusion through the buccal mucosa in vitro. Formulation F2 was identified as the most optimized, showing strong bioadhesive strength, enhanced drug solubility of 94.20 ± 0.56%, and drug diffusion of 92.56% over 7 hours.F2 formulations were determined to be stable during stability tests.

**Keywords:** Mucoadhesive buccal tablet, Olmesartan medoxomil, HPMC K4M, Sodium CMC, Poloxamer F407

## FORMULATION AND DEVELOPMENT OF MATRIX- MICROSPHERE OF ANTIDIABETIC DRUG (SAXAGLIPTIN) BY IONOTROPIC GELATION METHOD

Pooja Manohar Lomate, Mr. Aslam Tamboli, Mrs. Nikam Rohini
Dept. of pharmaceutics, R.P. College of Pharmacy Alani, Dharashiv, MH, 413501

Type 2 diabetes mellitus (T2DM) is a chronic metabolic disorder characterized by insulin resistance and progressive β-cell dysfunction, resulting in persistent hyperglycemia. Globally, over 537 million adults are affected. Saxagliptin, a DPP-4 inhibitor, is widely prescribed for glycemic control in T2DM but has a short biological half-life, requiring frequent dosing and impacting patient compliance. The present research work focus to develop sustained-release microspheres of Saxagliptin using the ionotropic gelation technique to enhance therapeutic efficacy and adherence. Sodium alginate served as the primary polymer, with ethyl cellulose incorporated at varying ratios to modulate drug release. Nine formulations were prepared and evaluated for particle size, morphology, micromeritic properties, entrapment efficiency, drug loading, and in vitro release kinetics. The optimized formulation produced discrete, spherical microspheres with good flow properties and entrapment efficiency ranging from 78.1% to 94.2%. Sustained drug release was observed for up to 9–10 hours, with enhanced release in acidic conditions simulating the gastric environment. Kinetic analysis indicated a diffusion-controlled release mechanism. Ionotropic gelation proved to be a simple, solvent-free, and non-toxic method for encapsulating Saxagliptin into microspheres, offering a promising strategy for sustained drug delivery. This approach may significantly improve patient compliance and therapeutic outcomes in the management of T2DM.

**Keywords**: Saxagliptin, Anti-diabetic, Microsphere, Ionotropic Gelation, Sustained Drug Release

## KOJIC ACID–NSAID–PALMITIC ACID HYBRIDS AS DUAL-ACTING AGENTS FOR HYPERPIGMENTATION AND INFLAMMATORY SKIN DISORDERS

Yogita Meshram and Prachi Khobragade
Anurag College of Pharmacy, Near Bhandara Road Railway Station, Warthi, Tah. Mohadi, Dist. Bhandara-441905 (M.S.), India
yogitameshram441@gmail.com

Inflammation and hyperpigmentation often occur together in dermatological conditions, yet most current therapies target these disorders separately. Kojic acid (KA), a well-known tyrosinase inhibitor, suffers from poor skin permeability, while non-steroidal anti-inflammatory drugs (NSAIDs) show strong anti-inflammatory activity but have limited application in cosmeceuticals. To overcome these limitations, novel KA–NSAID–palmitic acid hybrids were synthesized and evaluated as dual-function agents. Both monoester and diester derivatives of KA with ibuprofen, naproxen, diclofenac were prepared via DCC-mediated esterification and characterized using NMR, Mass spectroscopy, and HPLC (purity >97%). Their biological activities were tested through mushroom tyrosinase inhibition, anti-melanogenic effects in B16F10 melanoma cells, cytotoxicity on HEK cells, carrageenan-induced paw edema in rats, and ex vivo porcine skin permeation studies. The diester derivatives demonstrated significantly improved activity compared to parent compounds. Notably, ibuprofen-KA diester (IBUD) and diclofenac-KA diester (DICD) inhibited tyrosinase by 49% and 35% at 200 µM, respectively, and showed superior melanogenesis suppression in B16F10 cells (79%), surpassing KA alone (43%). In vivo, diesters produced greater edema reduction than NSAIDs. Skin permeation studies confirmed 2–3 fold higher delivery due to the lipophilic palmitic acid moiety. Importantly, cytotoxicity assays revealed minimal toxicity toward mammalian cells, even at higher concentrations. Overall, these findings highlight KA–NSAID–palmitic acid diesters as safe, dual-acting molecules with strong anti-melanogenic and anti-inflammatory properties, improved skin penetration, and promising potential as topical therapies for hyperpigmentation and inflammatory skin disorders.

**Keywords:** Kojic acid; NSAIDs; Palmitic acid; Melanogenesis; Inflammation; Tyrosinase inhibition; Skin permeation

## FORMULATION OF NANOCARRIER-BASED IN SITU GEL FOR IMPROVED BRAIN DELIVERY OF OXCARBAZEPINE

Ramya. M, J. Joysa Ruby, Rakasmita Pal, Nivia Remegia De Sa, Kritika Chandra, Patil Anjan Chandrashekhar.
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Soldevanahalli, Achit Nagar Post, Bengaluru, Karnataka, India.
ramyam.24.phce@acharya.ac.in

Epilepsy is one of the most common chronic neurological disorders affecting the central nervous system (CNS), characterized by recurrent seizures that may range from partial to generalized types. Despite existing therapies, many patients experience inadequate seizure control due to poor drug bioavailability or inconsistent dosing. This study focuses on the formulation and optimization of an oxcarbazepine-loaded nanoparticle-based in situ gel to enhance therapeutic efficacy and provide sustained drug release. Nanoparticles were prepared using high-shear homogenization followed by bath sonication, incorporating varying concentrations of glyceryl monostearate (100–200 mg), stearic acid (20–40 mg), and surfactants such as Poloxamer 188 and Tween 80. The nanoparticles were characterized using Fourier Transform Infrared Spectroscopy (FT-IR), Differential Scanning Calorimetry (DSC), Scanning Electron Microscopy (SEM), and zeta sizer analysis, yielding a particle size of 244 ± 71.20 nm, a polydispersity index (PDI) of 0.32 ± 0.05, and a zeta potential of −25 ± 6.45 mV. Entrapment efficiency was also evaluated and found to be satisfactory. The optimized nanoparticles were incorporated into an in situ gel using Poloxamer P-407 and Poloxamer P-188 (15–20% w/v) via the cold method. The gel formulations were evaluated for clarity, pH (6.23 ± 0.3), gelling capacity, gelation temperature and time, and rheological properties. Stability studies

ISBN: 978-81-980623-8-3

demonstrated the physical and chemical integrity of the formulation over time. In vitro drug release studies indicated a sustained release profile, supporting prolonged residence time at the administration site. The developed oxcarbazepine-loaded nanoparticle in situ gel system shows strong potential for improved epilepsy treatment through enhanced bioavailability and controlled drug delivery.

**Keywords:** Epilepsy, In situ gel, Oxcarbazepine, Poloxamer, nasal delivery.

**DEVELOPMENT AND EVALUATION OF A PROBIOTIC-BASED HERBAL GEL FOR SUSTAINABLE SKINCARE**

Gourab Garain, Sandeepa Yadav, Deepthi Swapna and Dr B A Vishwanath
Department of Pharmaceutics, Aditya Bangalore Institute of Pharmacy Education and Research – 560064
gourabgarain2002@gmail.com

The growing demand for natural and multifunctional cosmeceuticals has encouraged the exploration of probiotic-based formulations for improved skin health and sustainability. In this study, a novel probiotic-incorporated gel was developed using cell-free supernatants derived from fresh curd, rich in probiotic metabolites. The gel base was prepared with carbopol-940, glycerin, aloe vera extract, and neutralized using triethanolamine (TEA) or NaOH to achieve optimal viscosity and stability. Active ingredients such as niacinamide (Vitamin B3), panthenol (Pro-vitamin B5), and green tea extract were incorporated for added therapeutic and antioxidant benefits. Phenoxyethanol and ethylhexylglycerin were used as primary preservatives, with sodium benzoate or potassium sorbate as alternatives.The probiotic supernatant was extracted by centrifugation and incorporated into the gel base under aseptic conditions. The final formulation was evaluated for physicochemical parameters (pH, viscosity, clarity, and stability), microbiological safety, and consumer acceptability. The optimized gel exhibited a skin-friendly pH (~5.5), uniform texture, and improved hydration potential due to synergistic effects of probiotics and herbal actives. Patch testing confirmed safety, while preliminary results suggested potential benefits in skin barrier support and protection against oxidative stress.This study demonstrates the feasibility of integrating probiotics with herbal ingredients into topical gel systems, offering a promising cosmeceutical innovation that combines natural sustainability, therapeutic activity, and consumer safety. Such formulations hold strong potential for commercialization in the growing natural skincare market.

**FORMULATION DESIGN AND CHARACTERIZATION OF SELF MICRO EMULSIFYING DRUG DELIVERY SYSTEM FOR PRAVASTATIN**

Vivek Kumbharkar, Bhakti Matkar, Rohan Badhe, Sampada Dalvi
Department of Pharmaceutical quality assurance, Marathwada Mitra Mandal's College of Pharmacy, Thergaon, Pune, Maharashtra, India 411033
vivekkumbharkar8@gmail.com

The Pravastatin (PRAVA) self-micro emulsifying drug delivery system (SMEDDS) was developed to address the issues with poor solubility. Because PRAVA is almost completely insoluble in water, it exhibits irregular oral absorption and has an impact on bioavailability. According to saturated solubility studies, the oil phase was chosen for the formulation, and surfactants and co-surfactants were screened according to their capacity for emulsification. The self-emulsifying area was identified using ternary phase diagrams. It was determined that polyethylene glycol 200 (20%), almond oil (20%), and tween 80 (60%) were the components that were optimized. The droplet size, zeta potential, emulsification time, and rheological analysis were used to characterize the prepared SMEDDS. The trial validated PRAVA SMEDDS's potential for oral administration. The conclusion is that poorly water-soluble drugs like PRAVA can have their solubility and dissolution improved using the SMEDDS formulation technique.

**Keywords:** Pravastatin, SMEDDS, Phase Diagram, Dissolution Rate.

**REVOLUTIONIZING PHARMACEUTICALS: TAILORED 3D PRINTING SOLUTIONS FOR PERSONALIZED MEDICINE**

Gangeshwar.k
Department of Clinical Pharmacy Practice, Aditya Bangalore Institute of Pharmacy,Education and Research, Bangalore, Karnataka, India.
gangeshwark67@gmail.com

Personalized medicine has emerged as a transformative approach in modern healthcare, enabling treatments tailored to individual patient profiles, including genetic, physiological, and lifestyle factors. Traditional dosage forms provide limited flexibility in addressing patient-specific therapeutic requirements, often leading to complications such as polypharmacy, poor compliance, and suboptimal outcomes. Three-dimensional (3D) printing offers a promising technological breakthrough by enabling the design and fabrication of customized pharmaceutical formulations with precise control over dosage, drug release kinetics, and delivery systems. This work investigates the integration of 3D printing into pharmaceutical sciences, focusing on its applications in oncology and chronic pain management. Key innovations such as bioprinting, multi-material systems, and AI-driven formulation models are highlighted, with emphasis on patient-centric drug delivery approaches. Additionally, ethical and regulatory considerations, including risk analysis, equitable access, and patient data protection, are discussed. Findings suggest that 3D printing not only enhances therapeutic efficacy but also reduces adverse drug reactions, improves adherence, and holds the potential to revolutionize precision medicine.

**SYSTEMS BIOLOGY AND IN SILICO STUDIES OF THE BIOACTIVES FROM HYPERICUM PERFORATUM L. AGAINST PROSTATE CANCER**

Dhanushya Saravanan*, Praveen Sekar and Senthil Kumar Raju
Department of Pharmaceutical Chemistry, Swamy Vivekanandha College of Pharmacy, Tiruchengode, Namakkal, Tamil Nadu, India – 637205.
dhanushyasarvanan04@gmail.com

Prostate cancer is the second most frequent cancer in men worldwide. It has an age-adjusted incidence rate of 29.4 per 100,000 population and produces around 14.2% of new cancer cases in men. Hypericum perforatum L.is a perennial flowered plant, which contains anthraquinones, carotenoids, flavonoids, cumarine, naphthodianthrones, xanthones, volatile oils and proanthocyanidins. In this present study, we made an attempt to investigate the potential of phytochemicals from Hypericum perforatum L. using a systems biology approach. The phytochemicals were obtained from Dr. Duke's Phytochemical and Ethnobotanical database, IMPPAT, the Coconut database, Phytohub version 1.4, the Medicinal Plants database, The Natural Products Atlas, and the KNApSAcK Core system databases. SwissADME, ProTox 3.0, and CardioTOXCSM webservers were used to estimate phytochemical's physicochemical, pharmacokinetic, and toxicological profiles. OSIRIS Property Explorer was used to estimate the drug score and the results demonstrated the compound's druggable nature. Network modelling and enrichment analysis predicted the phytochemical's precise targets, which merely indicated that they would be quite active against prostate cancer. The statistical significance of the targets was determined using survival analysis and found that only the target SRC was statistically significant ($p < 0.05$). Then, molecular docking against SRC using Autodock tools was performed and compared with the co-crystallized ligand and standard. Owing to the various in silico studies, the compounds Apigenin, Kaempferol, Kieclorin, Luteolin 5,3-Dimethyl ether and Naringetol were identified as hit compounds. Among them, Kieclorin was highly active against SRC with good binding energies and interaction profiles. Thus, these compounds can be used against prostate cancer. However, further in vitro and in vivo studies are warranted.

**PC-253**

**DEVELOPMENT OF ROPINIROLE HYDROCHLORIDE LOADED NLC'S FOR BRAIN TARGETING THROUGH NASAL ROUTE FOR THE TREATMENT AND MANAGEMENT OF PARKINSON'S DISEASE**

ISBN: 978-81-980623-8-3

Shubham Bhosale, Samiksha Surwade, Avinash R. Tekade
Marathwada Mitra Mandal's College of Pharmacy, Thergaon, Pune, Maharashtra, India - 411033.
shubhambhosale3112@gmail.com

In the present investigation, Ropinirole Hydrochloride (RPH)-loaded Nanostructured Lipid Carriers (NLCs) were developed for brain targeting through the nasal route for the treatment and management of Parkinson's disease (PD). The objective of the study was to enhance the bioavailability of RPH, bypass hepatic first-pass metabolism, and overcome the blood–brain barrier (BBB) limitations by employing the nose-to-brain delivery approach. NLCs were prepared using glyceryl monostearate (solid lipid), cinnamon oil (liquid lipid), and surfactants (Tween 80 and Poloxamer 188) by high-pressure homogenization and optimized using a design of experiments (DoE) approach. The optimized NLC formulation exhibited particle size below 200 nm, narrow polydispersity index, high entrapment efficiency (>80%), and negative zeta potential ensuring stability. In-vitro release studies indicated sustained drug release following Higuchi and Korsmeyer–Peppas models, while ex-vivo permeation studies on goat nasal mucosa showed improved permeation with cinnamon oil-based NLCs compared to plain formulations. Histopathological evaluation confirmed the safety of the optimized formulation with no nasal mucosal damage. Stability studies revealed that the optimized formulation remained physically and chemically stable under accelerated conditions. Thus, the study successfully demonstrates that intranasal administration of RPH-loaded NLCs offers a promising strategy for direct nose-to-brain delivery, resulting in enhanced brain targeting, improved therapeutic efficiency, and minimized systemic side effects in the management of Parkinson's disease.

**Keywords:** Ropinirole Hydrochloride, Parkinson's disease, Nanostructured Lipid Carriers, Nose to-brain delivery.

**PC-254**

## DEVELOPMENT AND CHARACTERIZATION OF MULTIFUNCTIONAL CO-PROCESSED EXCIPIENT FOR DIRECT COMPRESSION

Poonam Charde; Mahima Pali; Nilesh Mahajan
Department of Pharmaceutical Sciences, Dadasaheb Balpande College of Pharmacy, Besa, Nagpur, Maharashtra, India.
chardepoonam09@gmail.com

Direct compression (DC) is a widely preferred method in tablet manufacturing due to its simplicity and cost-effectiveness. However, the success of this method largely depends on the functional properties of excipients. Single excipients often do not meet all requirements of direct compression, leading to the development of co-processed excipients. Co-processing aims to combine two or more pharmaceutically acceptable excipients to obtain a product with superior properties, without undergoing chemical changes.The objective of the present study was to develop and characterize a corn starch based multifunctional co-processed excipient (CCS) suitable for direct compression. Newly developed material was expected to offer enhanced flowability, compressibility, and compatibility. This reduced the number of incorporating excipients in tablets by converting native corn starch to multifunctional excipients. CCS was developed by cross-linking corn starch with epichlorohydrin and co-processed using poly-vinyl pyrrolidone (PVP) along with silicon dioxide (SiO2) and croscarmellose sodium (CrCs). Optimization was guided by the Sediment Delivery Model (SeDeM) Expert System, which evaluated key parameters including flowability, compressibility, and disintegration. Tablet formulations were then prepared using optimized blends and assessed for hardness, friability, disintegration, and dissolution, confirming their effectiveness for use in direct compression tablet formulation. Optimization confirmed a significant influence on compressibility, flow, and disintegration. FT-IR revealed the crosslinking, while XRD showed reduced crystallinity due to starch gelatinization. SEM images displayed predominantly spherical agglomerates with $SiO_2$ particles adsorbed on the surface. Enhanced solubility, swellability, flowability, and compressibility confirmed the successful development of a multifunctional excipient suitable for direct compression tablet formulation. These findings suggested that CCS may be potentially applied as one of the preferred multifunctional excipients for DC of tablets.

## FORMULATION, DEVELOPMENT AND EVALUATION OF NANOEMULSION LOADED TRANSDERMAL PATCH CONTAINING MIRABEGRON FOR TREATMENT OF OVERACTIVE BLADDER SYNDROME

Vikash Kumar Mali, Nandani Tiwari, Kantilal Narkhede, Sachin Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav – Vapi, India - 396191
Malivikash464@gmail.com

The present research study set out to formulate a nanoemulsion based transdermal patch loaded with mirabegron for the effective treatment of Overactive Blabber Syndrome (OBS), which is a condition affecting over 546 million individuals worldwide. Overactive Bladder Syndrome (OAB) is diagnosed by urgency of urination, usually with frequency and nocturia, and can significantly limit quality of life. Mirabegron was incorporated into a nanoemulsion system consisting of Maisine CC oil, Tween 80 as surfactant, Transcutol P as co-surfactant that was blended with hydrated HPMC K100M and PVA solution dissolved. Plasticizer PEG 400 was then added followed by casting the blend on glass petri plates using the solvent casting method. The optimized nanoemulsion contained 92.14 nm droplet size, 0.267 PDI, and -21.4 mV zeta potential, ensuring physical stability. The tensile strength of the optimized patch was 6.1 MPa, drug release at 24 hours being 90.02%, and transdermal flux being 28.84 µg/cm²/hr. The 3-month stability study showed >95% retention of drug and minimal physical degradation. Thus, here, developed nanoemulsion transdermal patch was efficient in delivering Mirabegron with improved permeation and controlled release, indicating its potential as a non-invasive treatment method of overactive bladder with advantages over the conventional oral therapy in terms of patient compliance and fewer GI side effects and other side effects.

**Keywords**: Nanoemulsion, Mirabegron, Transdermal Patch, Overactive Bladder

## FORMULATION AND EVALUATION OF FICUS PUMILA HERBAL GEL FOR ANTI-INFLAMMATORY ACTIVITY

J Joysa Ruby, B G Divya Sree, Meghana B H, Venkatesh D P,
Department of Pharmaceutics, Acharya & B M Reddy College of Pharmacy, Bangalore, Karnataka - 560107
divyasreebalasa@gmail.com

Inflammation is an imperative defense response that, if not controlled, needs treatment, but conventional synthetic anti-inflammatory agents, especially NSAIDs, have severe side effects such as gastrointestinal issues and cardiovascular hazards, so this study aimed to formulate, prepare, and test a herbal gel extract as a safer option for the treatment of inflammation. Leaves of Ficus pumila were harvested, identified, and extracted with maceration using ethanol and water, and six gel formulations (F1-F6) were prepared with varying concentrations of Carbopol 934, hydroxypropyl methylcellulose (HPMC), and xanthan gum as gelling agents with complete assessment involving phytochemical screening, physicochemical analysis (pH, viscosity, spreadability, extrudability), test for skin irritation , and evaluation of anti-inflammatory activity with carrageenan-induced paw edema model in Wistar rats. Phytochemical analysis has validated the existence of bioactive molecules such as carbohydrates, steroids, flavonoids, saponins, and glycosides, whereas formulation F1 (0.5% Carbopol 934) showed ideal characteristics with pH 7.10 ± 0.2, good spreadability (3.85 $gcmsec^{-1}$), satisfactory extrudability (89.7%), non-irritant nature (PII < 2.0), anti-inflammatory activity compared to reference diclofenac gel. The 0.5% Carbopol Ficus pumila gel is an effective, safe medicinal herbal option for treating inflammation with better patient compliance and fewer adverse effects than in synthetic counterparts.

**Keywords:** Ficus pumila, Herbal gel, Anti-inflammatory, Phytochemical, Carrageenan-induced paw edema model.

**DEVELOPMENT AND OPTIMIZATION OF A THERMORESPONSIVE CHITOSAN–POLOXAMER IN SITU NASAL GEL FOR ENHANCED BRAIN DELIVERY OF RIVASTIGMINE IN ALZHEIMER'S THERAPY**

Deepak Rathore, Dulendra Damahe, Priti Singh, Sachin B. Narkhede
Smt. B.N.B. Swaminarayan Pharmacy College, Salvav- Vapi, Gujarat, India – 396191
deep0012346@gmail.com

Rivastigmine, a widely prescribed cholinesterase inhibitor for treatment of Alzheimer's disease, is limited by poor oral bioavailability due to extensive first-pass metabolism and low ability to penetrate the blood–brain barrier (BBB). To target these concerns, the current study aimed to formulate a thermoresponsive in situ nasal gel from a chitosan–poloxamer system for intranasal drug delivery and resulting brain targeting. The gel was prepared using the cold method at varying concentrations of chitosan and poloxamer 407 and then optimized utilizing a $3^2$ factorial design. The optimized gel produced a gelation temperature of 32.5 ± 0.6 °C, suitable for nasal delivery. The optimized gel maintained standard physicochemical properties with an acceptable pH (6.1 ± 0.2), viscosity and mucoadhesive strength for nasal residence time. In vitro drug release studies showed prolonged drug release of eight hours, which followed Higuchi kinetics. Ex vivo permeation studies across nasal mucosa showed a 1.8-fold increase in drug permeation compared to drug solution alone. Histopathological analysis did not show any mucosal damage or irritation after application. Overall, the outcomes indicate that this thermoresponsive in situ nasal gel has great potential as a painless non-invasive delivery system for Rivastigmine which will promote patient compliance and therapeutics in Alzheimer's disease.

**Keywords:** Rivastigmine, chitosan, nasal delivery, spray dryer.

**PC-258**

**FORMULATION AND EVALUATION OF GASTRO-RETENTIVE FLOATING TABLETS OF DASATINIB FOR ENHANCED BIOAVAILABILITY**

Gajjar Sujal Kaushik, Sarode Gorakh, Anuradha Prajapati, Sachin Narkhede
Smt B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
sujalgajjar222@gmail.com

We formulated and tested gastroretentive floating tablets of Dasatinib to enhance its oral bioavailability by extending the duration it remains in the stomach and releasing the drug slowly. The aims were to enhance Dasatinib's dissolution in the stomach, minimize the dosing frequency, reduce first pass metabolism and enhance patient compliance through a well-formulated floating tablet system. To prepare these floating tablets we have employed Hydroxypropyl Methylcellulose (HPMC K4M) and Carbopol 934 through wet granulation technique followed by compression on 10 station rotary tablet press using 8 mm flat faced punches. Preformulation studies entailed solubility, melting point and UV absorbance. In vitro dissolution study was carried out with the help of USP Type II dissolution apparatus at 50 rpm in 0.1 N HCl for 24 hours to analyze the influence of polymer concentration on drug release and buoyancy. We have optimized the formulation using $3^2$ factorial design. Optimized formulations exhibited satisfactory flow properties, floating lag time of less than 30 seconds and floating duration of greater than 12 hours. The release of the drug was according to non Fickian diffusion and was best described by Higuchi and Korsmeyer-Peppas models. The best batch (F3) had 92.45% cumulative drug release after 24 hours. Stability studies indicated no significant change for one month. Dasatinib floating tablets formulated using HPMC K4M and Carbopol 934 enhanced gastric retention and controlled release of the drug leading to improved bioavailability and patient compliance.

**Keywords:** Dasatinib, gastroretentive, floating tablet, HPMC K4M.

**PC-259**

**Dolutegravir Nanosuspension: Formulation, Optimization, and In Vitro–In Vivo Characterization**

Monika Bhairam1, Ravindra Kumar Pandey1, Shiv Shankar Shukla1, Bina Gidwani1
1Columbia Institute of Pharmacy, Raipur (C.G.)
monikab430@gmail.com

This study aimed to develop and optimize a nanocarrier-mediated nanosuspension of dolutegravir, an antiretroviral drug with poor aqueous solubility, using a Design of Experiments (DoE) approach. The nanosuspension was prepared by high-speed homogenization followed by probe sonication, employing Soluplus as a stabilizer. The optimized formulation was evaluated for particle size, polydispersity index (PDI), zeta potential, drug content, morphology, and pharmacokinetics. In vitro dissolution and in vivo studies in Wistar rats were conducted to assess performance. The optimized dolutegravir nanosuspension exhibited a mean particle size of 337.1 nm with a low PDI and negative zeta potential, confirming stability. In vitro release and solubility were significantly improved compared to the pure drug. Pharmacokinetic studies demonstrated enhanced oral bioavailability, as reflected by increased AUC values. Sonication time was a critical factor influencing particle size. Differential scanning calorimetry and X-ray diffraction revealed an amorphous drug state in the nanosuspension, contributing to improved dissolution. The nanosuspension strategy effectively enhanced dolutegravir solubility and bioavailability, highlighting its potential as a promising delivery system for HIV therapy. Further clinical investigations are warranted to confirm therapeutic applicability.

**Keywords:** Dolutegravir, Nanosuspension, Solubility enhancement, Nanocarrier, HIV/AIDS

**FORMULATION, DEVELOPMENT AND IN VITRO SCREENING OF SPIRULINA AND INULIN FORTIFIED FUNCTIONAL CHOCOLATE**

Affan Parkar, Anas Memon, Akdus Khan, Abusufiyan Shaikh
Anjuman-I-Islam's Kalsekar Technical Campus, School of Pharmacy, New Panvel, India-410206.
affanparkar2004@gmail.com

The increase demand in healthy food category has encouraged the formulation of functional chocolate. In the present study, we formulated a nutritionally rich chocolate with low sugar by using optimum blend of dark (cocoa) and white chocolate bases, fortified with a prebiotic dietary fibre (inulin) and a protein rich cyanobacterium (Spirulina platensis). Dark chocolate is known for its antioxidant's polyphenolic constituents, while white chocolate help in providing desirable texture and creaminess. In our formulation, sugar was partly substituted with inulin, and the formulation was optimized for meeting sensory and texture target. Three final optimum formulations were evaluated using in vitro antioxidant activity (DPPH radical scavenging, reducing power assay), and simulated gastrointestinal digestive system. In addition, total phenolic content was also quantified. The Spirulina–inulin fortified chocolate demonstrated significantly high antioxidant activity ($P < 0.01$) and phenolic content ($P < 0.05$), as compared to control formulation. Furthermore, simulated studies with digestive system suggested the release of Spirulina nutrients and cocoa antioxidants. Our optimized formulation showed reduced sugar content, more protein content, and enhanced antioxidant potential, proving it a promising functional confectionery for the benefit of health-conscious users.

**Keywords**: Functional chocolate; Inulin; Spirulina; Antioxidant; DPPH; Reducing power assay

**PC-261**

**FORMULATION AND EVALUATION OF SOLID PERFUME CHAPSTICK FORTIFIED WITH VITAMINS AND ESSENTIAL OILS AS A TOPICAL PREPARATION FOR SKIN BRIGHTENING EFFECT**

K. S. Salve, Charuta Shinde
PES Modern College of Pharmacy (For Ladies) Moshi, Pune, Maharashtra, India, 412105
patilketki9@gmail.com

The present work was aimed at formulation and evaluation of a solid perfume chapstick, a topical preparation enriched with vitamin E and a blend of essential oils. The formulation fortified with Vitamin C is aimed to give skin brightening effect with smooth silage leaving a lasting, gentler, softer, subtler aroma when applied to the underarms. For this, five different blends of waxes were made to prepare the base for the ChapStick formulation. One from these blends, were optimised to get appropriate consistency necessary for the formulation. Then, six different preparations consisting of Vit C, Vit E, preservatives and varied proportion of essential oils like Lavender, Vanila, Jasmine and jojoba oil were used in specified concentration as base for the ChapStick perfume.

ISBN: 978-81-980623-8-3

The preparation with pleasant aroma, applicability and other properties was selected for the evaluation process to ensure the desirable properties in the ChapStick formulation. After the evaluation of ChapStick it was packed in a suitable container and labelled for display/presentation purpose

**Keywords:** Chapstick, Solid perfume, Essential oils, Vitamin C, Vitamin E

**DEVELOPMENT AND EVALUATION OF TOPIROXOSTAT-LOADED HPMC-G-PCL MICROSPONGES**

Krishna Kailash Poshia, Patel Chahat, Kantilal Narkhede, Sachin Narkhede
Smt B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
krishnaposhia8@gmail.com

Topiroxostat is used to treat hyperuricemia and gout. It is a selective xanthine oxidase inhibitor. However, it has limited oral bioavailability and low aqueous solubility (BCS Class II). The goal of this study was to improve its therapeutic performance by creating microsponges using hydroxypropyl methylcellulose-graft-poly(ε-caprolactone), a novel amphiphilic graft copolymer (HPMC-g-PCL). The copolymer's dual characteristics like hydrophilic swelling capacity of HPMC and biodegradable property of PCL helps to enabled efficient drug encapsulation and sustained release. Microsponges were prepared using the quasi-emulsion solvent diffusion method and optimized by a $3^2$ full factorial design by considering polymer concentration and stirring speed as critical factors. The optimized formulation results in production yield of 88.75%, entrapment efficiency of 92.10%, and cumulative drug release of 87% over 12 hours. The microsponges exhibit morphological characterization which confirmed spherical particles with interconnected pores, uniform particle size and good flow property. The release profile demonstrates sustained and controlled release behavior of drug by maintaining steady therapeutic levels and by reducing dosing frequency. Overall Topiroxostat-Loaded HPMC-g-PCL-based microsponges present a promising and innovative drug delivery system for the effective management of gout and presents the possibility for enhanced patient compliance and therapeutic outcome.

**Keywords:** Topiroxostat, HPMC-g-PCL, Microsponges, Sustained release, Gout management

**FORMULATION AND EVALUATION OF NANOCRYSTAL LOADED NASAL IN SITU GEL FOR INTRANASAL DRUG DELIVERY**

J. Joysa Ruby, Pachipala mokshitha, Manasa V, Venkatesh DP
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Bengaluru, Karnataka, India-560107
mokshitha3110@gmail.com

Epilepsy, affecting nearly 70 million people worldwide and 12 million in India, is marked by recurrent seizures due to abnormal brain activity, leading to significant physical, cognitive, and emotional impairment. Conventional treatments, including antiepileptic drugs, vagus nerve stimulation, ketogenic diets, and surgery, are limited by poor bioavailability and adverse effects, necessitating novel drug delivery approaches. Intranasal administration offers advantages such as bypassing the blood–brain barrier, rapid absorption, and improved therapeutic efficacy. In this study, oxcarbazepine, a BCS class II antiepileptic drug with poor solubility and bioavailability, was formulated into a nanocrystal-based in situ nasal gel. Nanocrystals were prepared by anti-solvent precipitation and incorporated into the gel via a cold process. The optimized nanocrystals showed a mean size of 244±71.20 nm, zeta potential of –25±6.45 mV, and needle-shaped morphology. The gel exhibited rapid sol-to-gel transition within 5 seconds at physiological temperature and maintained a nasal-compatible pH of 6.23±0.07. In vitro release studies showed sustained drug release, with nanocrystals achieving 85.24% release at 24 hours compared to 75.59% from the gel, indicating improved solubility and controlled release. Thus, it can be concluded that oxcarbazepine nanocrystal-loaded in situ gel is a promising intranasal delivery system capable of improving therapeutic efficacy, patient compliance, and overall epilepsy management.

**Keywords:** Oxcarbazepine, Nanocrystal Nasal delivery, In situ gel.

**DESIGN AND OPTIMIZATION OF HYDROGEL WITH ADIANTUM CAPILLUS EXTRACT FOR ENHANCED WOUND HEALING**

Karveer Babanrao Aghade, Suraj Daulatrao Bendre & Sachin Bhagwat Aglawe
Rashtrasant Janardhan Swami College of Pharmacy, Kokamthan, Kopargaon, Maharashtra, India, 423601.
aghadekarveer@gmail.com

Wounds are a major global health issue, often leading to death and prolonged suffering, particularly in the case of chronic wounds. Despite the development of numerous treatments, there is still a lack of effective, widely used wound dressings. Hydrogel-based dressings are promising due to their ability to maintain a moist environment conducive to healing, alongside their biocompatibility and permeability. This study investigates the formulation and optimization of a hydrogel containing Adiantum capillus extract, a plant known for its medicinal properties, including anti-inflammatory and antimicrobial activities. The hydrogel was prepared using various concentrations of Polyvinyl Alcohol (PVA) and Glyceryl Monostearate (GMS) as independent variables. Nine formulations were designed using a factorial experimental design, with evaluations of folding endurance, drug content, swelling ratio, and in-vitro drug release. The results indicate that batch F5 (with 1.5% PVA and 1% GMS) exhibited the optimal properties, including high drug content (96.7%), folding endurance (223 folds), and an excellent drug release profile, with 90.04% drug release at 12 hours. Additionally, the hydrogel demonstrated favorable physical characteristics such as a uniform appearance and moderate moisture content. Statistical analysis validated the optimal formulation, confirming the hydrogel's potential for sustained drug release and controlled delivery in wound healing applications. This study highlights the promising role of Adiantum capillus-based hydrogels in advancing wound care solutions.

**Keywords:** Hydrogel, Adiantum capillus, Wound Dressing, Controlled Release, Pteridaceae

**FORMULATION AND CHARACTERIZATION OF CRYPTOTANSHINONE LOADED NANOSTRUCTURED LIPID CARRIERS (NLC) FOR TOPICAL DELIVERY**

Sandhya Mishra1, Ravindra Kumar Pandey2, Shiv Shankar Shukla3
Department of Pharmaceutics, Columbia Institute of Pharmacy, Raipur, Chhattisgarh-493111, India1
Department of Pharmacognosy, Columbia Institute of Pharmacy, Raipur, Chhattisgarh-493111, India2
Department of Quality Assurance, Columbia Institute of Pharmacy, Raipur, Chhattisgarh-493111, India3
sandhyamishre2911@gmail.com

Cryptotanshinone is one of the tanshinones extracted from the traditional Chinese herb Salvia miltiorrhiza and belongs to solanaceae family. Cryptotanshinone shows anti-inflammatory activity and can be therapeutically used for the treatment of Rheumatoid Arthritis. As nanotechnology can better target arthritic joints and has higher bioavailability, it has demonstrated increased success in treating rheumatoid arthritis. Topical delivery of nanomedicines can overcome some of the disadvantages of oral delivery, such as decreased bioavailability because of poor solubility, unpleasant taste, and first-pass metabolism. The stratum corneum barrier of skin produce hindrance in the topical delivery of skin which can be overcome by various nanocarriers, amongst which Nanostructured lipid Carriers (NLC) is an effective carrier of the drug through the skin. The current study aims to create NLC that is loaded with cryptotanshinone and evaluate it in vitro. Cryptotanshinone loaded NLC was developed by using Hot Homogenization method. Further, the characterization of the prepared nano-formulation was done using Zeta sizer, Entrapment efficiency, Drug loading capacity and Drug release profile. The results revealed acceptable size range 158.1±5.4nm, high drug entrapment efficacy 80.98±1.9%, acceptable polydispersity index 0.260±0.039, zeta potential -28.91±0.65 mv and high drug loading capacity. The result revealed that NLC would be a promising carrier for topical delivery of cryptotanshinone for anti-inflammatory activity.

**Keywords:** Rheumatoid Arthritis, Nanotechnology, Nanostructured lipid Carriers, Topical delivery

**FORMULATION, QBD BASED OPTIMIZATION AND CHARACTERIZATION OF ANTIPSORIATIC TRANSETHOSOMAL GEL**

Disha Kesharwani*, Swarnali Das Paul1, Rishi Paliwal2, Trilochan Satapathy3
*&3 Columbia Institute of Pharmacy, Raipur, C.G. 1Shri Shankaracharya College of Pharmaceutical Sciences, Bhilai, C.G, India 2Faculty of Pharmacy, IGNTU, Amarkantak, Madhya Pradesh, India
disha@columbiaiop.ac.in

Psoriasis, a chronic autoimmune skin disease marked by inflammation and epidermal hyperproliferation, has garnered significant attention in dermatological research due to its complex pathophysiology, diverse clinical manifestations, and significant detrimental impact on patients' quality of life. Transethosomes are sophisticated lipid-based nanocarriers that can enhance the skin administration of hydrophobic medications, improving the effectiveness of treatment for psoriasis. The goal of the current study is to create a topical transethosomal gel of diosgenin that has efficient antipsoriatic action, enhanced skin penetration, and prolonged release. Diosgenin, a member of BCS class II, has a very low oral bioavailability yet has great potential for treating psoriasis. By preventing the synthesis of pro-inflammatory cytokines like TNF-α and IL-1β, which are crucial in psoriasis, it regulates the immune response. Thin film hydration was used to make the transethosomal gel, and the 32 response surface approach was used to optimize it. The developed transethosome was found to possess 184 nm particle size, 95.5% entrapment efficiency, 94.6 % drug release, and elevated anti-psoriatic. Using the Imiquimod (IMQ) model, an in-vivo antipsoriatic study was conducted on BALB/c mice. The treatment appreciably reduced the Psoriatic Area and Severity Index, thickness of epidermal layer, and inflammatory cytokines level. Based on the results, it can be concluded that the transethosomal gel loaded with diosgenin is an excellent delivery system for psoriasis since it improves skin penetration, sustained the drug release, and decrease the inflammation with little side effects.

**PC-267**

**TRANSFORMING FLURBIPROFEN DRUG DELIVERY: ENHANCING NANOEMULGEL FORMULATIONS WITH INNOVATIVE NANO-CARRIER SYSTEMS**

Manas Kumar Sha, Debashish Mohanty, Souvik Giri, Mihir Kumar Kar
Sri Jayadev College of Pharmaceutical Sciences, Naharkanta, Bhubaneswar, Odisha 752101

The current investigation aims to improve the distribution of flurbiprofen by developing advanced nanoemulgel formulations. The purpose is to boost the drug's effectiveness by enhancing its stability, controlled release, and bioavailability through innovative nano-carrier technology. This new delivery method could significantly change how poorly soluble medications are given. After thorough testing, peppermint oil, Tween 80, and PEG-400 were selected for use. An optimal oil to surfactant and co-surfactant ratio was determined using a pseudo-ternary phase diagram to create the nanoemulsion. Using a high-pressure microfluidization technique, the study produced nanoemulsions with the labels NEF1 through NEF9, which were then optimised using a 22 Central Composite Design (CCD). The particles had zeta potentials ranging from -35.19 to -18.91, sizes ranging from 69.5 nm to 297.1 nm, and drug release percentages ranging from 76% to 92.1%. Carbopol 934(1%) gel was mixed with the optimal formulation, NEF1, to create a 5% w/w Flurbiprofen nanoemulgel. When compared to a commercial product, this new formulation demonstrated an 80.12% improvement in drug release and good physical qualities, including 97.4% drug release. Additionally, the nanoemulgel held up well at 4°C for 90 days, suggesting that it could be used for topical drug administration.

**Keywords:** Nano-carrier technologies, Bioavailability, Pseudo-ternary phase diagram, High-pressure microfluidization, Central Composite Design (CCD)

**DEVELOPMENT OF FLOATING SOLID SELF NANOEMULSIFYING DRUG DELIVERY SYSTEM FOR IMPROVED GASTRIC RETENTION IN PEPTIC ULCER**

Pooja R. Nandane, Anurag K. Shahi, Nishant B. Awandekar, Swati N. Lade, Milind J. Umekar
Department of Pharmaceutics, Smt. Kishoritai Bhoyar Collage of Pharmacy, Kamptee Nagpur, Maharashtra, India- 441002
pooja.nandane1718@gmail.com

Peptic ulcer disease is a chronic gastrointestinal disorder caused by excessive gastric acid secretion and pepsin activity. The SNDDS is isotropic mixture of natural or synthetic oils, surfactant and co-surfactants to produce fine oil-in water nanoemulsion through gentle agitations in aqueous environment. This study aimed to formulate and optimize a Gastroretentive self-nanoemulsifying drug delivery system (SNEDDS) to enhance solubility, stability, and therapeutic efficacy by using a Potassium-Competitive Acid Blocker (P-CAB), offers superior acid suppression. Pre-formulation studies, including organoleptic evaluation, melting point, solubility analysis, and UV-Visible spectrophotometry, established the physicochemical characteristics of the drug. The formulation was optimized using Box-Behnken Design. Solid SNEDDS was prepared by adsorption to solid carrier method, produced free-flowing granules, further compressed into gastroretentive floating tablets. From the all 13 batches, optimized F9 batch showed the appropriate results. The optimized formulation showed prolonged buoyancy for 11.5 hours, drug release of 94.5% over 12 hours, satisfactory hardness (5.5 kg/cm$^2$), Thickness of 3.54 ± 0.027, and Friability is 0.48. The developed gastroretentive solid SNEDDS formulation demonstrated enhanced drug stability, and increased oral bioavailability of drug with ensuring prolonged gastric retention for the management of peptic ulcer.

**Keywords:** Peptic ulcer disease, Gastroretentive, Box-Behnken Design, SNEDDS, Floating tablets.

**INVITRO AND INVIVO EVALUATION OF THERMOSENSITIVE EAR HERBAL INSITU GELLING SYSTEM FOR OTITIS**

A.Geethalakshmi
Department of Pharmaceutics, Harsha College of Pharmacy, Nelamangala, Bangalore, Karnataka, India-562123
geelak74@gmail.com

Otitis media, a very common ear infection especially in children, remains a major global health concern, which often leads to ear pain, fever, discharge, and, if untreated might cause progressive hearing loss. The conventional and first line treatment relies on antibiotics and analgesics; however, their prolonged use leads to antimicrobial resistance and drug related side effects, which necessitates for safer and more effective alternatives. Utilising the ancient knowledge of traditional medicine, the antibacterial, antioxidant, and anti-inflammatory properties of garlic (Allium sativum) and ginger (Zingiber officinale) were investigated as potential therapeutic agents. The current study concentrates on creating an in situ gel based on ginger and garlic to modernise their delivery, providing extended retention, localized drug release, and minimized systemic exposure. The aim of this research is to develop thermo sensitive drug vehicles for ear infection Thermo sensitive ear drop was prepared using cold method by mixing thermo sensitive polymer pluronic F-127, viscosifying agent HPMC-E 50 LV and herbal extracts. Prepared nine formulations were evaluated for physical parameters like appearance, gelation temperature, pH, drug content, rheological properties, isotonicity, sterility test, in vitro diffusion study and antimicrobial testing demonstrated broad-spectrum efficacy, showing significant inhibition zones against both Gram-positive and Gram-negative pathogens. The drug released from selected F3 formulation provides sustained release over 8 hours period and showed excellent auricular tolerance. By bridging the gap between natural medicine and advanced pharmaceutical technology, this herbal in situ gel presents itself as a novel, safe, and promising alternative for the treatment of localised otitis.

**Key words:** Otitis, Allium sativum, Zingiber officinale, Thermosensitive in situ gel, Pluronic F-127

ISBN: 978-81-980623-8-3

The present study focuses on to develop and optimize Ribavirin-loaded silver nanoparticles for enhanced bioavailability and improved therapeutic efficacy in antiviral treatment. Ribavirin-loaded silver nanoparticles were formulated using a $2^3$ factorial design with silver nitrate concentration (2.5-5.0mM), reducing agent concentration (1.0-2.5% w/v), and stirring time (15-30 min) as independent variables. The nanoparticles were characterized for particle size, zeta potential, Polydispersity index, drug loading, entrapment efficiency, morphology, in vitro release, and stability. The optimal formulation AF8 achieved maximum desirability (0.999) through the factorial model design which produced particles with 40.7 ± 1.8 nm size and -32.5 ± 2.7 mV zeta potential and 0.189 ± 0.008 PDI and drug loading of 16.5 ± 1.2% along with an entrapment efficiency of 78.3 ± 3.9%. Drugs and excipients remained independent of each other according to FTIR and DSC testing. The biphasic drug release pattern of the nanoparticles showed 93.84% total drug discharge within 12 hours according to first-order ($R^2$=0.9925) and Higuchi ($R^2$=0.9948) kinetic patterns. The nanoparticles experienced only minimal modifications of their critical quality attributes throughout six months of accelerated stability evaluation while their particle size reached 45.6 ± 2.7 nm and their drug content held steady at 94.2 ± 2.1%. The introduction of silver nanoparticles loaded with Ribavirin shows potential as an efficient bioavailability enhancer for antiviral drugs thus potentially lowering medication doses and adverse effects.

## OPTIMIZATION AND CHARACTERIZATION OF LINAGLIPTIN TRANSFEROSOMAL GEL FOR ENHANCED TARGETED DELIVERY IN TYPE 2 DIABETES

Aditya Mishra, Souvik Giri, Archana Pattanaik, Mihir Kumar Kar
Sri Jayadev College of Pharmaceutical Sciences, Naharkanta, Bhubaneswar, Odisha 752101

Transfersomes are highly flexible and ultra-optimized lipid molecular aggregates with the objective of improved transdermal drug delivery. Transfersomes can penetrate the human skin, even the stratum corneum, by diffusing through pores that are smaller compared to their vesicle size. Transfersomes are a very promising carrier system for transdermal drug delivery, and chemicals like soya lecithin, Span 80, and methanol (all analytical grade) were utilized in making them. Various transfersomal formulation (F-1 to F-8) were formulated and compared for vesicle size and entrapment efficiency. The vesicle sizes of the formulations were 465.2 nm to 314.3 nm. Entrapment efficiency ranged from 66.35% to 79.76%. Among these, formulation F4 showed the lowest vesicle size and the highest entrapment efficiency and was the best among them. Formulation F4 was then formulated in a gel base employing 1%, 2%, and 3% Carbopol, and was analyzed for drug content, pH, spreadability, viscosity, and drug release behavior. The transfersomal gel formula exhibited controlled release of drug as 81.71% within 12 h. The optimized Linagliptin transfersomal gel overcame the skin barrier property with ease, facilitating better drug release and providing a promising candidate for transdermal delivery.

**Keywords:** Linagliptin, Transfersomes, Soyalecithin, Span-80andTween-80.

## Formulation And Evaluation Of Antimicrobial Ointment Containing Lantana Camara And Piper Betel Ethanolic Extract

Dnyaneshwar B. Borkar*, Suchita K. Bhoyar, Sanjay P. Wate
Department of Pharmaceutical Sciences, Anurag College of Pharmacy, Bhandara, Maharashtra, India – 441905
borkardnyaneshwar992@gmail.com

Formulating and testing an antibacterial ointment with ethanolic extracts of Piper betel (betel leaf) and Lantana camara (lantana) was the goal of this small project. Folk medicine has long utilized both of these herbs for their antibacterial and other medicinal qualities. In this investigation, a base ointment was made using ethanolic extracts of Piper betel and Lantana camara. Using a variety of bacterial and fungal strains, the ointment's antimicrobial activity was assessed using accepted microbiological methods. The physicochemical characteristics of the ointment, such as its stability, pH, consistency, and spreadability, were evaluated. The formulation showed potential efficacy against common infections, and the results showed significant antibacterial activity. In order to verify the ointment's biocompatibility, the study also evaluated its safety profile. The creation of the ointment by mixing these plant extracts offers a natural substitute for antibacterial therapy, which adds to the increasing demand for plant-based pharmaceuticals.

## FORMULATION AND EVALUATION OF SEMI-SYNTHETIC GEL CONTAINING TAGETES ERECTA AND CURCUMIN EXTRACT FOR THE TREATMENT OF ATOPIC DERMATITIS

Kale Digvijaysinh Ramesh, Shinde Kiran, Shah Darshan, Hapse Sandip

Atopic dermatitis (AD) is a chronic inflammatory dermatological disorder characterized by pruritus, dryness, and erythema, which significantly impairs the quality of life of affected individuals. Conventional treatments, including topical corticosteroids, immunomodulators, and emollients, often exhibit limitations such as adverse side effects and diminished therapeutic efficacy. This study aimed to design and evaluate a semi-synthetic gel formulation incorporating natural bioactive compounds from Tagetes erecta (marigold) and curcumin—both renowned for their anti-inflammatory, antioxidant, and wound-healing properties. The primary objective of this study was to formulate, optimize, and assess the efficacy of a semi-synthetic gel enriched with extracts from Tagetes erecta and curcumin as a potential therapeutic intervention for AD. The gel formulation was developed using a combination of natural and synthetic polymers, including carbopol and triethanolamine, and was rigorously evaluated for its physicochemical and microbiological characteristics. The gel demonstrated optimal spreadability, a pH within the skin's physiological range, and favorable viscosity, with stability observed under various storage conditions. In vitro assays revealed that the gel exhibited significant anti-inflammatory and antioxidant activities, as well as its capacity to mitigate both inflammation and oxidative stress. The anti-inflammatory effects were attributed to the presence of flavonoids and carotenoids from Tagetes erecta and curcumin, which modulated the expression of pro-inflammatory cytokines and enzymes. The antioxidant potential was linked to the ability of these bioactive compounds to neutralize reactive oxygen species (ROS) and reduce oxidative damage.Based on these findings, the semi-synthetic gel containing Tagetes erecta and curcumin extracts demonstrates considerable promise as a novel treatment modality for atopic dermatitis. Its favorable physicochemical properties, coupled with potent anti-inflammatory and antioxidant actions, suggest that it may offer a viable, natural alternative to conventional pharmacologic therapies for the management of AD.

## PROTACS IN CANCER THERAPY: BRIDGING INNOVATION AND CLINICAL APPLICATION

[1]ROHITH .M [2]G. Shravani
1,2 Vishnu Institute of Pharmaceutical Education and Research, Narsapur, Medak,Telangana– 502313, India
[2]Assistant Professor, Department of Pharmaceutical Chemistry, Vishnu Institute of Pharmaceutical Education and Research, Narsapur, Medak – 502313, India
shravani.g@viper.ac.in

A revolutionary development in precision medicine, proteolysis-targeting chimeras (PROTACs) use the ubiquitin–proteasome system (UPS) to specifically break down disease-causing proteins, particularly those linked to cancer. PROTACs have a more long-lasting therapeutic effect. This review examines creation, uses, and difficulties of PROTACs in cancer treatment, highlighting how they can be used to take advantage of cancer's weaknesses, boost effectiveness, and go past resistance. Clarifying PROTAC mechanisms and their advantages over conventional treatments, showcasing developments in tumor-selective PROTAC design, and talking about the difficulties in putting them into practice are the main goals. Recent studies show that PROTACs tag target proteins for destruction via enlisting E3 ubiquitin ligases. Studies that compare them to small-molecule inhibitors highlight how much more

ISBN: 978-81-980623-8-3

effective they are.Enhancingtumor specificity, stability, and selectivity is the goal of optimization using chemical engineering and bioinformatics. PROTACs efficiently break down cancer-causing proteins, surpassing the drawbacks of inhibitors. By using tumor-specific E3 ligases, therapeutic accuracy is increased and off-target effects are reduced. Design advancements improve tumor selectivity, control resistance, and improve delivery even more. PROTACs are transforming oncology by providing innovative treatments for tumors that are resistant and challenging to cure. Even if there areissues with safety, pharmacokinetics, and clinical translation, research is still being done for experimental discoveries with practical uses, which has potential to improve patient outcomes.

**Keywords:** PROTACs, ubiquitin-proteasome system, E3 ligase, precision medicine, tumorspecific targeting.

**DEVELOPMENT OF CHITOSAN-COATED PLGA NANOPARTICLES FOR TARGETED PULMONARY DELIVERY OF DOXORUBICIN IN LUNG CANCER**

J. Joysa Ruby, Shreyas N, Pavithra S, Venkatesh DP
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Soldevanahalli, Achit nagar post, Dr. Acharya Sarvepalli Radhakrishna Road, Bengaluru, Karnataka, India-560107
shreyas24l.krishna@gmail.com

Doxorubicin HCl is a widely used anticancer drug, yet its clinical utility is restricted by poor solubility, low bioavailability, and unfavourable pharmacokinetics in conventional formulations. This study aimed to develop and evaluate a chitosan-coated PLGA nanoparticle system for passive, pulmonary-targeted delivery of doxorubicin in non-small cell lung cancer (NSCLC). Nanoparticles were prepared via a double emulsion solvent evaporation method and subsequently transformed into inhalable powder through lyophilization. Physicochemical characterization was carried out using SEM, FTIR, DSC, zeta potential, particle size analysis, and in-vitro release studies. The optimized particles measured 248–348 nm, with zeta potential shifting from negative to positive after chitosan coating, confirming successful surface modification. In-vitro release demonstrated sustained drug release over 48 hours. Cytotoxicity testing on A549 cells showed that chitosan-coated nanoparticles significantly enhanced antiproliferative activity compared to free doxorubicin. Overall, this delivery system exhibited improved bioavailability, prolonged release, and greater therapeutic potential, suggesting that chitosan-coated PLGA nanoparticles may serve as an effective pulmonary platform for doxorubicin delivery in lung cancer treatment.

**Keywords:** Chitosan, PLGA, Doxorubicin, Nanoparticles, NSCLC.

**FABRICATION AND CHARACTERIZATION OF NANOSPONGES LOADED WITH AN ANTINEOPLASTIC AGENT**

Gopikrishna S Pai, Praveen Raj R, Titha Jose
Department of Pharmaceutics, St joseph's College of Pharmacy, Cherthala, Kerala, India-688524
gopikrishnaspai@gmail.com

The main objective of the present work is to fabricate and characterize nanosponges loaded with an antineoplastic agent. The nanosponge was formulated by incorporating the drug in to the particles. Doxorubicin Hydrochloride has a wide anticancer activity. The activity of Doxorubicin Hydrochloride can be improved and its toxicity can be diminished by enhancing the relative specific accumulation in the tumour regions. The potential of the drug to be incorporated into the dosage form was analysed by preformulation studies such as FTIR study, solubility studies and the organoleptic properties. The formulation was carried out using Emulsion solvent diffusion method. In this method an organic phase consisting of the drug and polymer in dichloromethane is added to the aqueous phase consisting of PVA in water. The mixture was stirred using a magnetic stirrer at 1000rpm. The formulation was evaluated by Percentage yield, Entrapment efficiency, SEM, Zeta potential, Particle size distribution, Differential Scanning Calorimetry, In-vitro dissolution study, Porosity. The SEM images showed that the particles are spherical and nano-sized. The best formulation was selected based on the results of Entrapment efficiency, In-vitro dissolution study etc. Nanosponges are commonly developed as a topical dosage form but this study can be used as a model to develop controlled or targeted drug delivery systems that are cheap, effective and easily affordable to the patients. This study resulted in porous nature of nanosponges which provides a channel for the release of the drug and the method is quick and reproducible.

**Keywords**: Doxorubicin Hydrochloride, FTIR study, organoleptic properties, Emulsion solvent diffusion, SEM.

**FORMULATION AND EVALUATION OF SILVER NANOPARTICLE BY USING TAMRINDUS INDICA FRUIT SHELL.**

Jyoti Gorakh Wagh, Manashree Mahesh Kapre.
MES College of Pharmacy, Sonai, Tal.Newasa, Dist.Ahmednagar, 414105
jjyothi2007@gmail.com

Nanoparticles has become a main branch of nanotechnology and there is an increasing commercial demand for nanoaprticlesdeu to the their ample applications.Nanoparticles play a major role in the field of engineering and medicine.This study investigates an efficient and sustainable route of Silver nanoparticles preparation from silver nitrate(AgNO3) using fruit shell extract of Tamarindusindica well known for their wide availability and medicinal property. For the synthesis of silver nanoparticles using the fruit shell extract of Tamarindusindica as a reducing agent from silver nitrate( AgNO3) has been investigated .The synthesis of silver nanoparticles mostly helps in enhancement of their Anticancer Activity.The synthesis of silver nanoparticles have been characterised using Ultaviolet Visible Spectroscopy, Fourier Transform Infrared Spectroscopy(FT-IR) ,Scanning Electron Microscopy (SEM) and X-Ray Diffraction Spectroscopy (XRD) and this synthesized silver nanoparticles shows an absorption peak at approximately 450 nm in the UV-visible spectrum.The morphological study of silver nanoparticles using SEM suggest that the nanoparticles are spherical in shape with a diameter around 20 to 100 nm.with their anticancer activity against MCF-7 Cellline .

**BIOACTIVES LOADED ELECTROSPUN 2D-NANOFIBERS: OPTIMIZATION, CHARACTERIZATION AND EVALUATION AS CHRONIC WOUND HEALING DEVICE.**

Sima Kujur, Parneet Kaur Deol, Indu Pal Kaur
University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India, 160014.
simakujur96@gmail.com

The study aimed to develop probiotic and fish oil-loaded 2D electrospun nanofibers (P&FO@NF) for chronic wound healing. Probiotics counter infections and modulate the wound environment, while fish oil rich in omega-3 fatty acids (33% EPA, 22% DHA) offers anti-inflammatory and regenerative effects. The two agents complement each other with FO enhancing probiotic viability and probiotic improving omega-3 bioavailability of fatty acids. However, instability of fish oil and reduced probiotic survival limit topical use. Hence, 2D NF are designed to overcome these issues, while the mimicking extracellular matrix, maintaining moisture balance and promoting tissue regeneration, and are considered wound healing devices. Optimization was carried out using Design of Experiments (DoE, JMP 17.1 custom design) to determine ideal emulsion and electrospinning conditions. The formulation composition and electrospinning parameters were optimized to obtain NF that showed uniform particle distribution (size 508 nm, PDI 0.228), stable morphology, and desirable physicochemical characteristics. Comprehensive characterization included FTIR, DSC, viscosity, thickness, and SEM analysis. Mechanical testing indicated good flexibility, while cytotoxicity studies on L929 cells demonstrated high viability (~72% at 1 µg concentration) without significant toxicity. Antibacterial assessments revealed effective inhibition of E. coli, MRSA, and Pseudomonas aeruginosa. In vivo evaluation using a diabetic wound model in male Wistar rats confirmed superior wound contraction (94.4%) compared to a marketed formulation (83.3%), with histological studies and biomarker estimation supporting enhanced tissue regeneration. These findings highlight the potential of P&FO@NF device as an efficient and biocompatible wound dressing for chronic wound management.

**FORMULATION AND CHARACTERIZATION OF PROTEIN MAGNETIC NANOPARTICLES FOR TARGETED DELIVERY OF PEMETREXED DISODIUM IN LUNG CANCER**

Patil Ajay Vitthal, J Joysa Ruby, Pranitha D B
Department of Pharmaceutics, Acharya & BM Reddy College of Pharmacy, Bengaluru, Karnataka, India-560107
pranitgadevaragunda@gmail.com

Lung cancer remains a leading cause of cancer-related mortality worldwide, with chemotherapy often restricted by systemic toxicity and insufficient drug targeting. Nanotechnology-based carriers present a promising strategy to overcome these limitations. In this study, protein-based magnetic nanoparticles (PMNs) were developed for inhalable delivery of pemetrexed disodium via the nasal route for targeted treatment of lung carcinoma. The nanoparticles were synthesized by the co-precipitation method and coated with albumin to enhance stability and biocompatibility. The optimized formulation (S7) displayed a mean particle size of 70.2 nm, narrow PDI, and favorable zeta potential, ensuring colloidal stability. Drug entrapment efficiency was notably high (82.42%) compared to less effective formulations (35.45%). In vitro diffusion studies demonstrated improved release, with PMNs achieving 58.81% drug diffusion at 60 minutes versus 42.49% for the pure drug. Ex vivo permeation studies across goat mucosa further confirmed enhanced permeability. Moreover, cytotoxicity evaluation on Ehrlich Ascites Carcinoma cells revealed stronger anticancer activity of PMNs than the free drug. Collectively, these results indicate that protein-coated magnetic nanoparticles significantly improve drug stability, release, permeability, and cytotoxicity, representing a promising nanocarrier system for targeted lung cancer therapy.

**EVALUATION OF STARCH FROM TARO (COLOCASIA ESCULENTA) AS DISINTEGRATING AGENT IN TABLET FORMULATION**

Kajal R. Ade, Sachin W. Lohe, Sanjay P. Wate
Department of Pharmaceutical Sciences, Anurag College of Pharmacy, Bhandara
Maharashtra, India- 441905
shubhamade1052000@gmail.com

Taro (Colocasia esculenta) contains about 70–80% starch, which can serve as a potential disintegrating agent in pharmaceutical tablet formulations. The aim of this study was to extract and evaluate starch from Taro and assess its suitability as a disintegrating agent. Starch was extracted using a simple process, and physicochemical tests confirmed its good properties without altering its chemical composition. The extracted starch was then used to prepare lactose tablets via wet granulation. The formulated tablets were evaluated for hardness, friability, weight variation, solubility, and disintegration time. Results showed that tablets containing taro starch disintegrated within 1.5 minutes, with wet granulation tablets exhibiting superior performance. These findings suggest that taro starch can be used as an effective alternative disintegrating agent in tablet dosage forms.

**Keywords**: Taro starch, Colocasia esculenta, Disintegrating agent, Tablet formulation.

**FORMULATION AND EVALUATION OF FINERENONE EXTENDED-RELEASE TABLETS USING EUDRAGIT RS100 AS A MATRIX FORMER: A COMPARATIVE STUDY WITH HPMC-BASED FORMULATIONS**

Neel Desai, Bhanushali Mayank Ratilal, Kantilal Narkhede, Sachin Narkhede
Smt B.N.B Swaminarayan Pharmacy College, Salvav, Vapi, Gujarat, India – 396191
neeladesai615@gmail.com

The present study was aimed at developing and evaluating extended-release matrix tablets of Finerenone which is a novel non-steroidal mineralocorticoid receptor antagonist, which uses Eudragit RS100 as the matrix-forming polymer. Finerenone is currently marketed as immediate-release tablets (Kerendia®) for the management of chronic kidney disease (CKD) which is associated with type 2 diabetes mellitus (T2DM) and requires daily administration. Developing an ER formulation could sustain therapeutic levels and reduce dosing frequency, and also improves patient adherence in chronic therapy. The hydrophobic, water-insoluble, yet permeable properties of Eudragit RS100 were chosen because they minimize the impact of gastrointestinal pH and motility on drug release, which is advantageous for poorly soluble medications. Direct compression was used to create these formulations, and pre- and post-compression parameters were assessed. The tablets hardness, friability, thickness, weight fluctuation, uniformity of drug content and in vitro release in gastrointestinal fluids were evaluated. The release profile of formulation of Eudragit RS100 was tested and compared with that of traditional HPMC hydrophilic matrix system. Compared to HPMC matrices, which are prone to variations due to agitation, the ionic environment, and gel strength, Eudragit RS100 formulations provide more stable, pH-independent, and controlled release profile. Stability tests was performed according to ICH guidelines which shows the robustness of the optimized formulation. Finally it was shown that ER finerenone tablets based on Eudragit RS100 has better control over drug release. This could result in better adherence, fewer doses, and increased therapeutic efficacy in the long-term management of CKD with type 2 diabetes

**INFLUENCE OF NATURAL STABILIZERS ON ESOMEPRAZOLE NANOCRYSTALS PREPARED BY ANTISOLVENT PRECIPITATION METHOD FOR ENHANCED ORAL BIOAVAILABILITY**

Mynam Harika and T. Balakrishna
Department of Pharmaceutics, V. V. Institute of pharmaceutical sciences, Gudlavalleru, Andhra Pradesh, India- 521356

Esomeprazole is proton pump inhibitor which has low aqueous solubility, therefore, reducing its oral bioavailability. The best course of action in increasing its therapeutic efficacy is to increase its solubility and rate of dissolution. The major aim of the research was to escalate the solubility and the dissolution speed of esomeprazole by planning nanocrystals of the drug using the technique of antisolvent precipitation. The nanocrystals of esomeprazole were made using the different stabilizers like the Guar gum, Karaya Gum, and polyethylene glycol 400 (PEG 400). The variability of such stabilizers was applied in the creation of eight formulations (F1, F2, F3, F4, F5, F6, F7 and F8). Particle size, drug content and in vitro drug release of the formulations were determined. The Fourier-transform infrared spectroscopy (FTIR) and differential scanning calorimetry (DSC) were used in characterization. The best formula released 99% of the drug in only 5 minutes, which is much more than the pure drug. The FTIR analysis showed that there was no drug-stabilizer interaction, which showed excipient compatibility. DSC data indicated lower crystallinity, which shows a successful formation of nanocrystal. Antisolvent precipitation as a method to produce stable Nanocrystals of Esomeprazole is simple and has high probability of producing Esomeprazole nanocrystals with high dissolution rates that can enhance oral bioavailability. Optimized formulation F8 showed 99 percent of the drug in 5 minutes. No convincible drug-excipient interaction. Enhanced dissolution because of reduced particle size and associated increase in surface area and effective stabilization Reduced crystallinity shown by DSC.

**Keywords**: Esomeprazole, Antisolvent precipitation, Guar gum, FTIR, Dissolution enhancement.

Topiroxostat is a xanthine oxidase inhibitor and is used in the treatment of gout. Since it has low therapeutic efficacy due to poor aqueous

ISBN: 978-81-980623-8-3

solubility and dissolution rate, this study aims to develop and evaluate fast dissolving tablets (FDTs) containing nanoparticles of Topiroxostat to enhance it's solubility and dissolution rate. Solvent diffusion technique was used to prepare nanoparticles with spherical crystallization employing PVP-K30 and SLS as formulation variables. A $3^2$ full factorial design was used to optimize process parameters. Among the F1-F6 batches, the F4 batch demonstrated proper spherical shape, uniform size, and enhanced dissolution properties. The tablets were prepared by direct compression using Croscarmellose sodium (CCS) and Crospovidone as superdisintegrants. The absence of possible drug-polymer interactions was confirmed by FTIR analysis. The optimized formulation exhibited a disintegration time of 23 ± 0.10 sec, wetting time of 25 ± 0.22 sec, and significantly enhanced drug release as compared to the pure drug and it's marketed formulation. Stability studies were conducted for over a month which indicated no major changes in drug content, solubility and dissolution parameters. This study depicts that fast dissolving tablets containing nanoparticles of Topiroxostat provide enhanced dissolution and rapid drug release, putting forward a promising approach for enhanced therapeutic management and treatment of gout.

## DEVELOPMENT OF NANO ICARITIN LOADED POLYMERIC SCAFFOLD FOR DIABETIC WOUND HEALING.

Tharani.M, Vadivelan Ramachandran and Jawahar Natarajan
Department of pharmacology, Indira Gandhi Institute of Pharmaceutical Sciences, Perumbavoor, Kerela-683549
tharanidheiva058@gmail.com

A diabetic wound is a complex, chronic non-healing wound that occurs in approximately 34% of patients with diabetes and is commonly referred to as Diabetic Foot Ulcer (DFU). Biomaterial-based scaffolds have entered this sector to provide structural stability and a favourable environment for cellular regeneration, thus imitating original tissue in function. To formulate Icaritin NLC-loaded Chitosan/ PVA/ Methylcellulose (ICT- Cs/PVA/MES) scaffold and study its effect on oxidative stress and inflammation via NrF 2 /HO-1 axis for diabetic wound healing in rats. Icaritin NLC-loaded Cs/PVA/MES scaffold was formulated by freeze-drying technique, characterized and evaluated for compatibility, morphology, degradation and in vitro drug release studies. In vitro SRB assay was carried out. It was further tested for diabetic wound healing studies on STZ-induced diabetic rats with an excisional wound model. The formulated scaffold was in a spongy texture and highly porous. In vitro SRB assay showed no cytotoxicity and in scratch assay within 48hr significant migration was observed in ICT-NLC The in vivo studies showed complete wound closure within 21 days in the ICT scaffold group with a significant increase in the expression of NrF2/ HO-1 and a significant decrease in the expression of NF-kB, TNF-α and IL-6.It was concluded that the developed scaffold could be a promising treatment strategy for diabetic wound healing.

**Keywords**: Icaritin, diabetic wound healing, nanoparticles, scaffold.

## FORMULATION AND EVALUATION OF TOPICAL NANO-EMULGEL USING ANTI-INFLAMMATORY DRUG FOR THE TREATMENT OF ARTHRITIS

Kalavathy DJ and Rachana BL
Associate Professor, Department of Pharmaceutics, Visveswarapura Institute of Pharmaceutical Sciences, BSK II stage, Bangalore-560070.
kaladj222@gmail.com

The current research study was focused on the formulation of Celecoxib-based nanoemulsion hydrogel for the treatment of arthritis. Celecoxib, used to manage pain and inflammation. is hindered by several limitations, hence, a transdermal topical applicalion containing Celecoxib nanoemulgel was formulated. Pseudo-ternary phase diagrams were constructed using tea tree oil as oil phase, PEG 400 as surfactant, ethanol as co-surfactant, and water. 4:1 ratio of PEG 400 to ethanol (Smix) was found to yield the largest isotropic region. The formulations were further optimized using a 32 factorial design.Formulation C6 demonstrated the most desirable properties, including a globule size of 221.3 nm, a polydispersity index of 0.572, drug content of 95.2±0.16%, drug release of 75.34±0.44% after 8 hours, viscosity of 214±0.36 cP. The selected nanoemulsion (C6) was then incorporated into a Carbopol 940 gel base at concentrations of 1%, 1.5%, and 2% to produce three different Celecoxib nanoemulgels (C6F1, C6F2, C6F3). These Emugels were evaluated for pH, Viscosity, Spreadability, Extrudability, Drug content and % drug release formulation.Among these, formulation C6F3 exhibited the best performance, with a drug content of 98.04±0.22% by UV spectrophotometer and 98.13% by HPLC method and a drug release of 64.11±0.43% at 6 hours. Thus, it can be concluded that the objective of this study was successfully achieved through the development of the Celecoxib nanoemulgel, which offers enhanced therapeutic efficacy in treating arthritis and effectively managing pain and inflammation, underscoring its reliability as a topical treatment option for patients.

**Keywords:** Celecoxib, Transdermal , Nanoemulgel, Tea tree oil, Carbopol 940.

## FORMULATION DEVELOPMENT AND EVALUATION OF MEDICATED LOZENGES OF AMISULPRIDE

Riddhi Nitesh Padhiyar, Ansari MD Ashfaque, Anuradha P. Prajapati, Sachin B. Narkhede
Smt. B.N.B. Swaminarayan Pharmacy College, Salvav-Vapi, Gujarat, India – 396191
rixdhi19@Gmail.com

This study focuses on the formulation and evaluation of medicated lozenges which contain Amisulpride, which is used for the effective management of post-surgery emesis. A complexation approach was used using where β-cyclodextrin was used, where a 1:2 ratio of drug-to-carrier was demonstrated. The most significant improvement in solubility to prevail is the poor aqueous solubility of Amisulpride. Methods for preparing lozenges were used such as heating and congealing methods with excipients like sucrose, isomalt, HPMC E5, stevia, ginger, and citric acid which is selected based on preliminary compatibility and functionality studies. For systematic optimization a $3^2$ full factorial design was used, using sucrose and HPMC E5 levels as independent variables, while disintegration time, hardness, and drug release profile were used as dependent responses. The optimized formulation shows a disintegrated time of 9.41 minutes, hardness of 10.7 kg/cm², and it also shows cumulative drug release behavior, which supports product stability. The results show the successful development of stable and patient friendly lozenges of Amisulpride with enhanced solubility, and it has effective drug delivery. This work shows the importance of rational formulation design, application of factorial optimization, and integration of natural sweeteners and flavoring agents which improve both therapeutic efficacy and patient compliance. The study provides an effective strategy to the development of novel dosage forms which are intended for the management of emesis in clinical practice.

## DESIGN AND EVALUATION OF CRISABOROLE-LOADED NANOSUSPENSION GEL: A NOVEL TOPICAL APPROACH FOR ATOPIC DERMATITIS THERAPY

Rehan Siraj Sharif, Ahir Hemini Mukeshbhai, Sachin Narkhede
Smt. B.N.B. Swaminarayan Pharmacy College, Salvav – Vapi, India - 396191
sharifrehan77@gmail.com

The present study is related to Formulation, Development and Evaluation of Nanosuspension of a drug Crisaborole which is poorly soluble PDE-4 inhibitor loaded in the gel for the treatment of Atopic dermatitis. The Research of last ten years reveals that the atopic dermatitis(AD) is influenced by immunologic, environmental, and genetic variables where the Atopic dermatitis affects 15–30% of children and 2–10% of adults worldwide, highlighting the condition's pervasiveness. There are several marketed formulations are Available for the Atopic dermatitis patient out of which the most desirable one thought is topical as the onset of action is quick. Crisaborole Nanosuspension was developed by Wet media milling method which contain Poloxamer 188 and Poloxamer 407 as Surfactants and Hydroxypropyl Methyl Cellulose K 100M (HPMC K 100M) and Polyvinyl Pyrrolidine K 30 (PVP K-30) as stabilizer in proportion 1:3, optimized by 32 Factorial Design and then suitably incorporated into nanogel with

ISBN: 978-81-980623-8-3

addition of 0.5% Carbopol 940 for topical delivery of nanosized Crisaborole. To determine the advantage of Crisaborole Nanosuspension Gel for skin application the in vitro experiment was performed using Franz diffusion cell. Best batch F8 has shown Maximum particle size 139.9 nm, zeta potential -11.1 mV and cumulative drug release 95.47%. The optimise batch was subjected to stability study for 30 days the visual evaluation showed no change in physical appearance during stability study after stability. This present study indicates that recently developed Nanosuspension based Topical gel can be used safely for treatment of Atopic Dermatitis.

**Keywords:** Atopic dermatitis (AD), Nanosuspension Gel, Crisaborole, 3Full factorial Design

**DEVELOPMENT OF MUPIROCIN SLN-LOADED BIGEL FOR ENHANCED TOPICAL MANAGEMENT OF SKIN INFECTIONS**

Mahek Kamlesh Prajapati, Gandhi Nisha Jagdish, Anuradha P. Prajapati, Sachin Narkhede
Smt B.N.B. Swaminarayan Pharmacy College, Salvav- Vapi, India - 396191
prajmahek2004@gmail.com

This work describes the development of a bigel-based topical drug delivery system containing mupirocin-loaded solid lipid nanoparticles (SLNs) for enhanced antibacterial treatment. Mupirocin is a highly potent and effective topical antibiotic, especially against Staphylococcus aureus and methicillin-resistant bacteria (MRSA); however, its clinical effectiveness is compromised due to faster systemic absorption and renal elimination after topical administration. To overcome these constraints, SLN were formulated by the solvent emulsification-evaporation method with Phospholipon 90G as the lipid matrix and Poloxmer 407 as the surfactant. The developed SLN formulation showed a mean particle size of 120nm, zeta potential of -22.5mV, and entrapment efficiency 86%, reflecting excellent colloidal stability and drug encapsulation. The SLNs were loaded in a bigel system containing hydrogel and oleogel phases to improve skin retention, spreadability, and drug permeation. The bigel was examined for physicochemical characteristics such as pH, viscosity, spreadabiliy, and homogeneity and also for its bioavailability. Sustained release of the drug from the SLN-loaded bigel (73.2% for 14 hours) compared with the commercial mupirocin ointment (92% for 8 hours) reaffirmed its controlled release nature. Antimicrobial evaluations also confirmed good activity against S. areus. The bigel was shown to be physically and chemically stable over 3 months' storage. These results indicate that the SLN-based bigel developed here provides a valuable opportunity for sustained topical delivery of mupirocin, with the potential to improve therapeutic efficacy and patient compliance in the treatment of localized skin infections caused by bacteria.

**Keywords:** Solid lipid nanoparticles, bigel, mupirocin, sustain release action, topical delivery, and bacterial skin infection.

**FORMULATION AND OPTIMIZATION OF SANDWICHED OSMOTICALLY CONTROLLED DUAL DRUG DELIVERY SYSTEM FOR ANTIDIABETIC THERAPY**

Mangesh D Godbole, Chinmay Jungare*, Abhiroop Nakade
Dadasaheb Balpande College of Pharmacy, Besa Nagpur, Maharashtra, India-440037.
chinmayjungare4255@gmail.com

In the treatment of diabetes mellitus, conventional antidiabetic therapies frequently fall short due to erratic medication levels, frequent dosing and low patient compliance. The objectives of the presented research was to design a sandwiched osmotically controlled dual drug delivery system for the simultaneous administration of linagliptin (DPP-4 inhibitor) and empagliflozin (SGLT-2 inhibitor) for steady and regulated delivery, to improve glycemic control. After completing a thorough preformulation characterisation, Empaglifozin was mixed with HPMCK4M, KCl and Lactose Monohydrate along with talc and magnesium stearate to make one layer. Same was done with Linagliptin to make another layer. For giving it sandwiched osmotic nature, a push layer was made by mixing KCl, Lactose monohydrate, talc and magnesium stearate. The 8 mm round standard concave punches were used to compress tri-layer tablet. The obtained tablets were coated with cellulose acetate (5%, 10%, w/w) in conventional coating pan to develop semipermeable membrane. The delivery orifices was developed mechanically to precisely control the release of drugs. FTIR, DSC and XRD study concluded that drug and polymers were compatible with each other. Hardness, friability, weight variation and dissolution tests were performed. In vitro study showed that, improved formulation have zero-order release kinetics, regardless of agitation or pH. Batch F3 having 5% cellulose acetate coating showed empaglifozin and linagliptin 98.8626 % and 97.453 % release respectively at the end of 24 h dissolution study in 0.1 M HCl. It was concluded that, sandwiched osmotic tablets can be a game-changer for simultaneous delivery of antidiabetic drug for longer-acting effects and better patient compliance.

**Keywords:** Sandwiched osmotic tablet, Diabetes mellitus, Controlled release, Osmotic pump.

**COMPARATIVE STUDY OF AI AND CYCLODEXTRIN TOWARDS BETTERMENT OF SOLUBILITY OF SOME APIS WITH POOR WATER SOLUBILITY**

P. S. Gaikwad

Inclusion complexation with Cyclodextrin (CD) is an industrially feasible approach to modify the physicochemical properties of poorly water-soluble drugs. In the case of CD techniques, the experimental determination of a complex binding constant is frequently troublesome and tedious. Therefore, AI-assisted computer-based methods have been applied as a device for anticipating CD association constants, which reduces the duration of assessment of the same and for identifying various driving forces associated in inclusion phenomenon. In this research work, CD inclusion complexation of Piperine (PIP) was prepared in aqueous medium, indicating 1:1 stoichiometry, which is previously confirmed by computational chemistry within a very short period. This computational methodology also predicted the inclusion mode of piperine inside b-cyclodextrin, different interactions & affinity of drug towards CD which is important for predicting the stability of inclusion complexes. As a result, AI is an effective tool in the exploration of Novel drug delivery and when it is combined with the Cyclodextrin approach, it may produce a less expensive, more researcher-friendly, less time-consuming technique in formulation development.

**FORMULATION AND EVALUATION OF COLON TARGETING MESALAMINE ABLET USING POWDER COATING TECHNIQUE**

Akanksha A Talokar, Anushree P Thelkar, Prasad R Deshmukh, Dipti B Ruikar
P. R. Pote Patil College of Pharmacy, Amravati, Maharashtra 444603.

Powder coating is a novel solvent free coating technology that has gained increasing attention in pharmaceutical field as an alternative to conventional liquid–based coating techniques. In this process, dry powder particles consisting of polymers plasticizers and functional excipients are applied onto solid dosage form and subsequently fused under controlled thermal or plasticizer conditions to form a continuous film. The advantages of powder coating is solvent free process, patient safety, uniform coating, control release, stability, taste masking and the disadvantage of powder coating is limited substrate, equipment requirement, coating defects, scaleup language. The objectives is to load mesalamine in chitosan macroparticles and formulate and evaluate powder coating enteric coated tablet using mesalamine loaded chitosan beads for colon targeting. Mesalamine loaded chitosan beads by using inotropic gelation method. FTIR confirmed the successful entrapment of mesalamine in chitosan beads having 39% drug loading with 58.5% Entrapment efficacy. Core tablets were prepared by direct compression method having mesalamine loaded chitosan beads with MCC, mannitol, sodium starch glycolate, povidone and evaluated for appearance, thickness (5.22mm), hardness (5.5kg/cm2), friability (0.7%), weight variation (250.2mg) and disintegration time (17mins). The powder coating to core tablets of mesalamine and mesalamine loaded beads were carried out using Eudragit L100, HPMC, PEG 6000, and talc by compression coating. Powder coated tablets were successful evaluated for enteric tablet by acid uptake and disintegration in 6.8 pH phosphate buffer, In-vitro drug released study showing controlled released of mesalamine about 76.67% in 6 hr at 6.8 pH phosphate buffer. In

ISBN: 978-81-980623-8-3

conclusion, dry powder coating technique successfully evaluated for colon targeting mesalamine delivery.

**Keyword:** Powder coating, chitosan beads, mesalamine, colon targeting.

**COST OF ILLNESS ASSOCIATED WITH TYPE 2 DIABETES MELLITUS MANAGEMENT: A PROSPECTIVE ANALYSIS OF DIRECT AND INDIRECT COSTS**

Chaitanya Guduru, Nagasri Juluri, Sravanthi Cherukupalli, Thanuja Chaapala, Ramesh Adepu
Vikas College of Pharmaceutical Sciences, Rayanigudem, Suryapet – 508 213

This prospective observational study assessed direct and indirect costs associated with Type 2 Diabetes Mellitus management. The study was conducted in private clinics in Suryapet through case reports and patient interviews about monthly expenditures. One hundred patients aged above 30 years with Type 2 DM were included, comprising equal gender distribution. Statistical analysis was performed using regression analysis and T-test. Results showed 63 patients (63%) had diabetes complications while 37 (37%) were without complications. Total annual cost of illness for patients with complications was 510.96 USD compared to 319.68 USD for those without complications, showing significant difference of 191.28 USD. Patients with complications spent 225 USD annually for medications versus 93.72 USD for those without. Laboratory charges were higher for complicated cases (78.60 USD) compared to uncomplicated ones (45.12 USD). This study highlights the substantial financial impact of diabetes complications, with complicated patients spending approximately 60% more on healthcare. The findings emphasize the need for effective complication prevention strategies to reduce economic burden on patients and healthcare systems.

**Keywords**: Type 2 Diabetes Mellitus, Cost of illness, Healthcare expenditure, Direct costs, Diabetes complications.

**COMPARATIVE STUDY OF VITAMIN C CONTENT IN MARKETED COSMECEUTICALS**

Vijayalakshmi M, Sushmitha Y M, Rizwana D, Abhiram R A, Prasanna G S
Department of Pharmaceutical Chemistry, S.B.D. Institute of Pharmacy
vijayalakshmi44961@gmail.com

Vitamin C (L-ascorbic acid) is a water-soluble vitamin commonly applied in cosmetical products due to its strong antioxidant effect, its capacity to enhance collagen production, and its possible application in the prevention of oxidative and UV-related harm to the skin. As more consumers are increasingly willing to use vitamin C-based skin care formulations, there is a need to assess the real amount of vitamin C available in the marketed formulations. The aim of the current study was to determine the vitamin C level of marketed cosmeceutical products by the use of the 2,6-dichlorophenol indophenol (DCPIP) titration technique. The redox mechanism offers an easy and effective means of vitamin C quantification because it can be used in changing the color of DCPIP dye, which is blue, to colorless. Several of the marketed formulations with lots of lotions, serums, and creams were chosen to be analyzed. The findings showed that there was significant difference in vitamin C level of various brands and formulations. It was observed that some products have had a closer vitamin C content compared to the claim on the label and others had a relatively lower content. These findings are significant because it indicates the stability of the products, the differences in formulation, and the possibility of the therapeutic effectiveness in preserving the skin condition. Finally, the paper emphasizes the significance of analytical quality control over cosmeceutical products and reveals the formulation (Sugar pop sunscreen) with the greatest proportion of vitamin C (96.8) of all the ones analyzed. This article highlights the importance of vitamin C in cosmetics product as well as the importance of rigorous assessment of the products sold to the market in order to guarantee their effectiveness and safety to the consumer.

**Keywords:** L-ascorbic acid, cosmeceuticals, antioxidant, collagen synthesis, DCPIP method

**DESIGN, SYNTHESIS AND COMPUTATIONAL MECHANISTIC STUDY OF 1,3-THIAZOLE DERIVATIVES TO CONSTRAINT CARDIOVASCULAR RISK FACTORS**

Samruddhi S. Khonde, Vikrant L. Salode, Nilesh B. Banarase
Department of Pharmaceutical Chemistry, P. R. Patil Institute of Pharmacy, Talegaon (S.P.), Maharashtra, India.

Cardiovascular diseases (CVD) remain the leading cause of global mortality, necessitating novel therapeutic agents targeting underlying risk factors. This study focuses on the design, synthesis, and computational evaluation of novel 1,3-thiazole derivatives aimed at modulating cardiovascular risk. Thirty-five novel thiazole analogues were designed using in silico approaches, including molecular docking and quantitative structure-activity relationship (QSAR) analysis, targeting the angiotensin-converting enzyme (ACE), a key regulator implicated in hypertension and cardiac dysfunction. Databases such as PubChem, ZINC, and Enamine confirmed the novelty of selected compounds. Molecular docking revealed promising binding affinities, particularly for compounds AP27, VP21, and VP20. ADME profiling indicated favourable drug-like properties and toxicity assessments predicted acceptable safety profiles. Eight lead compounds were synthesized via microwave-assisted methods and structurally characterized by IR, NMR, and mass spectroscopy techniques. Preliminary acute oral toxicity studies using OECD guidelines demonstrated non-lethal toxicity levels for selected compounds. The integrative approach of computational predictions and experimental validations suggests these novel thiazole derivatives as potential candidates for cardiovascular therapeutics. Further pharmacological and clinical evaluations are warranted to establish their efficacy and safety profiles.

**Keywords:** Thiazole, Cardiovascular risk, Drug design, Molecular docking, QSAR

**FORMULATION AND OPTIMIZATION OF DIRECTLY COMPRESSED FLOATING TABLETS CONTAINING IBUPROFEN AND RABEPRAZOLE**

Suprith B S, Srividya K, Prakruthi K N, S S Prasanna
Department of Pharmaceutics, S.B.D. Institute of Pharmacy
suprithbs08@gmail.com

The goal of this study was to create gastro-retentive floating tablets with a mix of Rabeprazole and Ibuprofen that would improve stomach retention and provide sustained release by employing the direct compression method. The proton pump inhibitor Rabeprazole is acid-labile and needs gastric protection, while the widely used NSAID Ibuprofen frequently irritates the stomach when released quickly. To extend gastric residency and offer a concurrent therapeutic advantage, a floating drug delivery system (FDDS) was created. Formulations ($F_1$–$F_9$) were made with different amounts of HPMC as the release-retarding polymer, and effervescent agents such as citric acid and sodium bicarbonate. Characterization of the powder blend (bulk density, tapped density, Carr's index, Hausner's ratio, and angle of repose) verified that the majority of formulations had acceptable flow characteristics. The lag time for floating varied from 15 to 39 seconds, with $F_5$ exhibiting the shortest lag time. All formulations maintained their buoyancy for over 12 hours. In summary, the combination floating tablets of Rabeprazole and Ibuprofen were able to maintain buoyancy for an extended period of time. The formulation that showed the most promise among all of them was $F_4$, which combined the potential for enhanced therapeutic efficacy in gastro-retentive drug delivery with a rapid floating onset.

**Keywords:** Ibuprofen, Rabeprazole, Floating drug delivery system, Gastro-retentive tablets, Direct compression.

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by β-amyloid (Aβ) aggregation, tau hyperphosphorylation, oxidative stress, and cholinergic dysfunction, leading to cognitive

ISBN: 978-81-980623-8-3

decline. Despite promising leads, clinical translation is hindered by poor aqueous solubility and limited brain permeability due to the restrictive blood–brain barrier (BBB). Our laboratory previously developed two naturally inspired multifunctional neuroprotective molecules, F24 (Eur J Med Chem. 2020;198:112257) and F76 (Bioorg Med Chem. 2021;46:116385), with strong anti-Alzheimer potential, but their utility was restricted by unfavorable pharmacokinetics. To address these limitations, we engineered an exosome-based nanocarrier system using human plasma-derived exosomes for enhanced solubility, stability, and targeted brain delivery. Drug loading was optimized through a hybrid probe sonication–incubation method, yielding stable vesicles with high encapsulation efficiency. Exo-F24 and Exo-F76 exhibited sustained release at physiological pH and potent inhibitory activity against acetylcholinesterase (AChE) and butyrylcholinesterase (BChE), with enzyme kinetics confirming their inhibition mechanism. Both formulations also displayed significant antioxidant activity (DPPH assay), metal chelation, and effective BBB permeability (PAMPA-BBB). In SH-SY5Y neuroblastoma cells, they protected against $H_2O_2$-induced oxidative stress, confirming neuroprotective efficacy. Pharmacokinetic studies in rodents revealed improved oral bioavailability, sustained systemic exposure, and efficient brain distribution. In vivo, Y-maze testing in scopolamine-induced amnesia models demonstrated enhanced memory performance and cognitive protection. These findings highlight exosome-based delivery as a promising strategy to overcome solubility and delivery barriers of neurotherapeutics, establishing Exo-F24 and Exo-F76 as multifunctional candidates for AD therapy.

**THE DEVELOPMENT OF BIODEGRADABLE MICROPARTICLES IN REGENERATIVE MEDICINE**

Chandra Shekhar Reddy Bonepally1, Krishnaveni bommineni 2
Sarojini Naidu Vanita Pharmacy Mahavidyalaya, Tarnaka, Secunderabad -500017
Rbvrr womens college of pharmacy, Barkathpura, Hyderabad – 500027

Biodegradable microparticles are emerging as versatile platforms in regenerative medicine due to their ability to promote tissue repair and deliver therapeutics in a controlled, localized manner. Their tunable physicochemical properties, derived from both synthetic polymers and natural biomaterials, allow precise modulation of degradation rates, drug release kinetics, and surface characteristics, making them highly adaptable for clinical applications. Recent innovations in microparticle engineering have focused on optimizing fabrication techniques such as microfluidics and electrospraying to enhance uniformity, scalability, and reproducibility. Functional modifications have enabled their use as multifunctional systems for three-dimensional scaffolding, stem cell expansion, and targeted modulation of inflammatory responses, expanding their role beyond traditional drug delivery vehicles. Preclinical studies have demonstrated the efficacy of biodegradable microparticles in skeletal tissue regeneration, osteoarthritis treatment, and wound healing, with sustained therapeutic effects and reduced systemic toxicity. These advances highlight their potential to address unmet needs in precision medicine and tissue engineering. However, no clinically approved products are currently available, indicating significant translational gaps. While biodegradable microparticles demonstrate strong promise for regenerative therapies, barriers remain, including long-term biocompatibility evaluation, large-scale manufacturing challenges, and regulatory hurdles. Overcoming these limitations requires interdisciplinary collaboration across biomaterials science, pharmaceutical technology, and clinical research. Continued innovation and investment in this field are expected to accelerate the development of clinically viable solutions, offering improved therapeutic efficacy, personalized treatment strategies, and enhanced patient outcomes.

**APPLICATION OF REFINED SUNFLOWER OIL FOR THE DEVELOPMENT OF SELF- MICROEMULSIFYING DRUG DELIVERY SYSTEMS FOR POORLY WATER SOLUBLE EMPAGLIFLOZIN**

Nilesh Kulkarni, Anushka Kale, Shashikant Dhole
Department of Pharmaceutics, Progressive Education Society's, Modern college of Pharmacy (For Ladies), Moshi, Pune, Maharashtra, India Affiliated to Savitribai Phule Pune University, Pune, Maharashtra, India.

Empagliflozin, a sodium-glucose co-transporter 2 (SGLT-2) inhibitor, is used in the management of Type II Diabetes Mellitus, exhibits low solubility, and variable therapeutic efficacy. Refined Sunflower Oil is distinguished by being an edible, pharmaceutically approved lipid that is rich in polyunsaturated fatty acids, particularly linoleic acid, which improves membrane fluidity and facilitates lymphatic absorption. Solubility of EMP was carried out in various oils (Sesame oil, Orange oil, Castor oil, Olive oil, Labrafac, MCT, Sefsol, Virgin coconut oil, Hydrogenated coconut oil, Ref. sunflower oil, and Safflower oil), surfactant (Tween 20, Span 80, Plurol Oleique CC 497, Lauroglycol FCC) and co surfactant (PEG 200, PEG 400, and Propylene Glycol). The pseudo ternary phase diagram was constructed to identify microemulsion zone. The liquid SMEDDS formulations were developed using combination of Oil (refined Sunflower oil), Surfactant (Tween 20), co surfactant PEG 200 (L1) and oil (refined Safflower oil), Surfactant (Tween 20), and co surfactant PEG 200 (L 2). The liquid formulations were converted into solid using adsorbent Neusilin® US2. The liquid and solid SMEDDS formulations were evaluated for % transmittance, Drug content, in-vitro dissolution study and characterized for globule size and zeta potential. The liquid L1 and its converted solid formulation exhibited globule size of 516.7 nm, 870 nm and zeta potential value of -11.71 mV, S1 (-27.24 mV) respectively. The solid formulation exhibited improvement in in-vitro dissolution rate as that of plain drug. The developed solid SMEDDS formulation comprising of Oil (refined Sunflower oil), Surfactant (Tween 20), co-surfactant PEG 200 has the capability to improve the solubility.

**Keywords**: refined Sunflower oil, refined Safflower oil, globule size

Abietic acid is the predominant resin acid found in the oleoresin of various coniferous species, especially those in the genus Pinus. It is a major diterpenoid constituent of coniferous resin, has witnessed a remarkable journey from its traditional use in industrial applications to its emergence as a highly promising scaffold for modern drug discovery. In this research study, binary inclusion complex of abietic acid with polymerized cyclodextrins EPi-β-CD and CM-Epi-β-CD were prepared by three methods. Phase solubility was done to determine stiochiometric ratio and complexation efficiency. The complexes were characterized by FTIR and dissolution studies. Results of Phase solubility revealed AL type graph with R2 value 0.988 and 0.997 for both polymerized cyclodextrins with stability constant of 10671 M-1 and 13528 M-1. These complexes were subjected to pharmacokinetics study leading to improved solubility and bioavailability. In conclusion, polymerized cyclodextrin are prominent in improving the physical and chemical properties of BCS class II/IV drugs. This approach shows promise in overcoming solubility challenges associated conventional drugs may contribute to better treatment outcomes. In future, research and clinical studies are essential to validate the effectiveness and safety of bioactives as a viable delivery system.

The aim of the present study was to prepare, optimize and characterize Ibuprofenamine hydrochloride proniosomes. The objective of the research was to prepare proniosomes by using maltodextrin as a carrier

ISBN: 978-81-980623-8-3

using the slurry method. A central composite design was used for the optimization with the total surfactant loading(X1) and lipid concentration(X2) as the independent variables. Prepared proniosomes were characterized by particle size analysis and entrapment efficiency. Multiple regression analysis and contour plots were used to relate the dependent and independent variables. An optimized batch (IFop) was prepared and evaluated for particle size analysis, zeta potential, entrapment efficiency, SEM, TEM, DSC, XRD, In-vitro dissolution, and it was found that optimized formulation has a particle size of 158.3 nm, zetapotential value of -17.2, drug entrapment of 77.72%, drug release of 89.29%, the release profile of niosomes fits best with the Higuchi model. SEM and TEM images confirmed the proniosomes were nearly spherical; XRD analysis confirmed the amorphization of the drug. This work has demonstrated the use of central composite design in optimizing Ibuprofenamine hydrochloride proniosomes. The optimization model predicted the levels of X1 and X2, to minimize the particle size and maximize the entrapment efficiency. Over all, in this study, an approach to generating niosomes incorporating Ibuprofenamine hydrochloride using a slurry-based proniosome technology was demonstrated.

**Keywords:** Ibuprofenamine hydrochloride, Span 60**,** central composite design.

guttalarasajna@gmail.com

Neurodegenerative diseases and cancer cases are increasing rapidly worldwide and treating them with existing drugs is becoming difficult due to their complex mechanisms, limited efficacy of current therapies, and the discovery of shared molecular pathways. Our study is focused on developing novel heterocyclic nitrogen containing molecules like pyrazole and pyrimidinone derivatives that can precisely target specific disease mechanisms, such as protein aggregation in neurodegeneration and uncontrolled cell growth in cancer. we synthesised 5-acetyl-3,4-dihydropyrimidine derivatives, 5-(2,2,2-trifluoroacetyl)-3,4-dihydropyrimidine derivatives. 5 substituted 3 phenyl pyrazole derivatives and 2,2,2- trifluoro,5-substituted 3 phenyl pyrazole derivatives using Biginelli reaction a multicomponent reaction, their structures were confirmed by using IR. NMR and Mass Spectroscopy, further they were studied their ADMET profile using Biosig lab software and performed In-silico docking studies on proteins involved in neurodegeneration and cancer proteins using Pyrx and Biodiscovery studio where 2 hydroxy benzaldehyde and 2 nitro benzaldehyde derivatives shown a significant docking score was obtained, These compounds were synthesized and were studied for In-vitro and In-vivo studies.

**Keywords**: 5-acetyl-3,4 dihydropyrimidine derivatives, 5-(2,2,2-trifluoroacetyl)-3,4-dihydropyrimidine derivatives. 5 substituted 3 phenyl pyrazole derivatives and 2,2,2- Trifluoro,5-Substituted 3 phenyl pyrazole derivatives, Biginelli reaction.

**DEVELOPMENT OF ETHOSOMAL GEL INCORPORATING FENOPROFEN FOR TOPICAL MANAGEMENT OF RHEUMATOID ARTHRITIS**

Chandana A R and Vazir Ashfaq Ahmed
Department of Pharmaceutics, Ikon Pharmacy College, Bidadi, Ramanagara (T&D), Karnataka, India - 562109
Chandanagowda981@gmail.com

In the present research, a topical gel of fenoprofen incorporated in ethosomes was formulated for the effective management of rheumatoid arthritis. The objective of the study was to enhance the dermal delivery of fenoprofen by overcoming the limitations of conventional topical systems such as poor penetration and reduced bioavailability. Ethosomes were prepared by the cold method using varying concentrations of phospholipid and ethanol The prepared ethosomes were evaluated for vesicle size, zeta potential, entrapment efficiency and drug release, and it was found that formulation F3 (prepared using optimized phospholipid and ethanol ratio) had a vesicle size of 165.2 nm, zeta potential –31.1 mV, maximum entrapment efficiency 85.3% and cumulative drug release of 96.66% over 24 h out of all the six formulations (F1 to F6). The DSC and FTIR analysis of formulation F3 suggested that the drug remained stable with no interaction with excipients. SEM and optical photomicrography confirmed the spherical shape and uniform size of the vesicles. The ethosomal dispersion of F3 was incorporated into carbopol gel and evaluated for pH, spreadability, drug content, washability, stability and in-vitro diffusion. Comparative ex-vivo permeation studies across rat skin showed that the ethosomal gel exhibited enhanced drug flux compared with marketed gel. Thus, it can be concluded that ethosome-based topical gel of fenoprofen is a promising approach for the effective treatment of rheumatoid arthritis.

**Keywords:** Fenoprofen, ethosomes, topical gel, rheumatoid arthritis, drug delivery.

**BAMBOO SAP–CENTELLA ASIATICA FORMULATION: A DUAL-MECHANISM APPROACH TO WOUND HEALING**

Honnesh G R, M Padhmasree, B A Vishwanath, Paranjyothi
Department of Pharmaceutics, ABIPER, Bangalore, Karnataka-560064.

There is growing interest in plant-based products for wound healing because of their safety, versatility, and sustainability. The present research focused on developing a dual-action natural wound-healing cream that combines Bamboo sap and Centella asiatica extract in a stable topical dosage form. Bamboo sap, rich in silica, amino acids, vitamins, and antioxidants, was incorporated for its hydrating, anti-inflammatory, and tissue-protective properties, while C. asiatica extract, containing asiaticoside and madecassoside, was selected for its well-documented wound-healing, collagen-stimulating, and regenerative effects. The cream was prepared by an oil-in-water (O/W) emulsion method. The oil phase consisted of coconut oil, liquid paraffin, and cetyl alcohol, while the aqueous phase included glycerin, Bamboo sap, and C. asiatica extract. Tween 80 was used as an emulsifier and methyl paraben as a preservative. Both phases were separately heated to 70–75 °C, combined under continuous stirring, homogenized, and then cooled gradually to obtain a smooth, semi-solid cream. The formulation exhibited suitable physicochemical properties, with a pH of 5.8–6.3, compatible with skin. Spreadability was measured at 7.2 ± 0.3 g·cm/sec, ensuring ease of application, while viscosity ranged from 18,500 to 19,200 cP, indicating a consistent semi-solid texture. Organoleptic evaluation confirmed that the cream was homogeneous, visually acceptable, and non-irritating upon application. The combined action of Bamboo sap and C. asiatica supports hydration, barrier repair, collagen production, and tissue regeneration. In conclusion, this dual-action herbal cream may be a promising formulation for wound healing, with potential therapeutic applications.

**Keywords:** Phytocosmetic, Bamboo sap, Centella asiatica, Natural healing cream, Oil-in-water emulsion, Wound healing.

**DEVELOPMENT, OPTIMIZATION, AND IN VITRO EVALUATION OF 5-FLUOROURACIL-LOADED CHITOSAN NANOPARTICLES FOR SUSTAINED RELEASE**

Raj Sujit Jahan and Nurjamal Hoque
Faculty of Pharmaceutical Science, Assam down town University, Sankar Madhab Path, Gandhi Nagar, Panikhaiti, Guwahati, Assam, India, PIN – 781026.
jahanrajsujit@gmail.com

This study aimed to develop and optimize 5-Fluorouracil (5-FU)-loaded polymeric nanoparticles for sustained release and enhanced anticancer efficacy. A Box-Behnken Design (BBD) with 15 experimental runs was employed to evaluate the impact of three independent variables—Chitosan (100-200 mg), Ethyl cellulose (100-200 mg), and Tween 80 (2-4 ml)—on the dependent variables: drug loading (Y1) and entrapment efficiency (Y2). Regression analysis identified a best-fit linear model for both responses ($R^2 = 0.8146$), confirming the model's predictive accuracy and significant p-value (0.0015). An optimization process using a desirability function successfully generated an optimized formulation. The experimental values for drug loading (59.36% ± 1.3) and entrapment efficiency (89.56% ± 1.4) were in close agreement with the predicted values, validating the statistical model's robustness. Fourier-Transform

ISBN: 978-81-980623-8-3

Infrared spectroscopy (FTIR) analysis indicated minor spectral shifts, confirming the chemical compatibility of 5-FU with the polymeric excipients through weak hydrogen bonding. Particle size analysis revealed a Z-average of 337.8±1.764 nm and a low polydispersity index (PDI) of 0.219, indicating a uniform, monodisperse nanoscale formulation. Scanning Electron Microscopy (SEM) confirmed the spherical morphology and smooth surface of the nanoparticles, which is advantageous for stability. In - vitro drug release studies demonstrated a sustained profile, with 97.56±1.2% of the drug released over 14.4 hours. The developed nanoparticle system shows significant potential for the effective and controlled delivery of 5-FU, providing a strong foundation for future in vivo and clinical investigations to enhance the pharmacokinetics of chemotherapeutic agents.

## FORMULATION, DEVELOPMENT AND CHARACTERISATION OF TRANSDERMAL DRUG DELIVERY SYSTEM CONTAINING LOVASTATIN FOR THE TREATMENT OF DYSLIPIDEMIA

Mohammad Azhar Baba*, S.Guruprasath, K.Jyothi
Department of Pharmaceutics, Palamuru University, Thirumala Hills, Mahabubnagar, India, 509001.
Mohammadazhar7112@gmail.com

Nanoparticles are widely studied drug delivery system because of many benefits like controlled release ability to reach target, smaller particle size enhancement of therapeutic activity and reduction of toxicity. SLN's ( Solid Lipid Nanoparticles) are novel nanoparticulated systems which invited substantial attention as a drug delivery carrier. The design of the study was to develop and evaluate Lovastatin solid lipid nanoparticles, loaded into transdermal patch. Lovastatin, a lipid lowering agent, because of its low bioavailability ( 5% ) and shorter biological t½ is a suitable drug to formulate into transdermal form. SLN's containing drug and non-toxic lipids ( stearic acid , cholesterol, glycerol monostearate ) tween 80 and PEG 400 as surfactant and co- surfactant were prepared using microemulsion process. FTIR study reports indicated that there was no interaction between Lovastatin and other excipients SLN's were assessed for their particle size, entrapment efficiency, PDI ( Poly dispersity index ) and in vitro studies. Scanning Electron Microscopy reports shown that nanoparticles are spherical shape and has size range 130-249 nm. PDI was found out to be in the range of 0.186-0.376 percent entrapmenmt efficiency was between 74.3 + 0.8-93.5 + 1.8.The SLN's were loaded into a transdermal patch formulated using HPMC in varying concentration. All the prepared patches were assessed for flatness, folding endurance, tensile strength, moisture uptake, moisture content and were determined to be in essential range. The SLNP2 in-vitro release rate studies shows better release than remaining formulations ( SLNP1 and SLNP3 ) and it was selected as optimized formulations.

**Keywords:** Lovastatin, lipids, SLN's, Microemulsion, Transdermal patch.

## DEATH RECEPTOR-5 GUIDED NANOPARTICLE THERAPY: TARGETED Γ-SECRETASE INHIBITION FOR METASTASIS AND RELAPSE SUPPRESSION IN TNBC

Bamudi Ajay Kumar1, P.S.S. Sai Kiran2, Sampathirao Yeswanth2, Mihir Kumar Kar1
1Sri Jayadev College of Pharmaceutical Sciences, Naharkanta, Bhubaneswar, Odisha
2Aditya University, Surmampalem, Kakinada, Andhra Pradesh

Triple Negative Breast Cancer (TNBC) is distinguished by aggressive growth, high metastasis, and frequent relapse. Conventional therapies often fail to eradicate breast cancer stem cells (BCSCs), which drive recurrence and dissemination. Targeting the Notch signaling pathway, crucial for both angiogenesis and BCSC maintenance, offers a new avenue for intervention; however, traditional γ-secretase inhibitors such as DAPT suffer from off-target effects that limit clinical utility. In this study, we engineered lipid–polymer hybrid nanoparticles (LPNPs) conjugated with anti-Death Receptor-5 (DR5) antibodies to deliver DAPT specifically to TNBC cells. The resulting DAPT-DR5-LPNPs displayed optimal size (132±1.72nm), high encapsulation efficiency (85.6%), and robust cytotoxicity in DR5-overexpressing MDA-MB-231 TNBC cells. Cellular assays confirmed efficient nanoparticle uptake, enhanced apoptosis, and marked suppression of Notch-1, MMP-2/9, and EMT markers, indicating reduced metastatic potential. In vivo, DAPT-DR5-LPNPs induced significant tumor regression in mouse models. These findings demonstrate that DR5-mediated targeting enables potent and selective elimination of both BCSCs and differentiated TNBC cells, offering a promising solution to overcome metastasis and relapse while minimizing systemic toxicity.

## MESOPOROUS SILICA NANOPARTICLES AS A NOVEL CARRIER FOR ENHANCING ORAL BIOAVAILABILITY OF POORLY WATER-SOLUBLE DRUGS

Harshita Shambhu Hegde and Vazir Ashfaq Ahmed
Department of Pharmaceutics, Ikon Pharmacy College, Bidadi, Ramanagara (T&D), Karnataka, India -562109
harshitashegde@gmail.com

In the present investigation, mesoporous silica nanoparticles (MSNs) of Gliclazide, a poorly water-soluble BCS class II antidiabetic drug, is formulated to enhance its solubility and dissolution. MSNs are prepared by the precipitation method and drug loading is carried out using solvent evaporation. The prepared formulations are evaluated for compatibility, entrapment efficiency, particle size, morphology, crystallinity, solubility and in vitro release. FTIR confirmed no drug–excipient interactions. Entrapment efficiency ranged between 17.61% and 88.29%; with batch F4 showing the highest value. Particle size analysis indicated nano-sized particles (164.5 nm), while SEM revealed spherical particles with smooth surfaces. XRD analysis showed the absence of sharp crystalline peaks, confirming transformation of Gliclazide into an amorphous form within the MSN matrix. Solubility studies demonstrated a significant increase compared with pure Gliclazide. The optimized formulation (F4) is further compressed into fast dissolving tablets (FDTs) by direct compression. In vitro dissolution studies revealed that F4 tablets achieved 98.44% drug release within 40 minutes, demonstrating enhanced dissolution compared to pure drug. Stability studies conducted at 40 ± 2 °C /75 ± 5% RH for one month; indicated no significant changes in drug content or release profile, confirming formulation stability. Overall, MSN-based FDTs of Gliclazide effectively improved solubility and dissolution, which may lead to enhanced bioavailability and better therapeutic efficacy in diabetes management.

## GOLD METAL COMPLEXES: FROM ANCIENT ALCHEMY TO MODERN APPLICATIONS

Manisha G Suryavanshi
Hi Tech college of Pharmacy, Padoli, Nagpur Highway, Chandrapur, Maharashtra, India.
442406.
manishasuryavanshi259@gmail.com

Gold metal complexes have emerged as a dynamic class of compounds with diverse applications across catalysis, materials science, and biomedicine. This review provides a comprehensive overview of the structural diversity, synthetic methodologies, and characterization techniques associated with gold(I) and gold(III) complexes. The unique electronic configuration of gold, influenced by relativistic effects, imparts distinctive properties to its complexes. These include high stability, soft Lewis acidity, and strong affinity for sulfur and phosphorus-containing ligands. Such features have enabled the design of gold(I) and gold(III) complexes with tailored reactivity and biological activity. In recent years, gold complexes have gained significant attention in medicinal chemistry, especially for their potential as anticancer agents. Unlike traditional platinum-based drugs, gold compounds often exhibit lower toxicity profiles and novel mechanisms of action, such as inhibition of thioredoxin reductase and induction of immunogenic cell death. Notably, recent studies have explored gold complexes in the treatment of cisplatin-resistant lung cancer, underscoring their therapeutic promise Recent advances in medicinal chemistry are highlighted, particularly the development of gold-based therapeutics targeting cancer and drug-

ISBN: 978-81-980623-8-3

resistant diseases. By integrating structural insights with emerging biomedical applications, this review underscores the evolving role of gold complexes in modern science.

**Keywords:** Gold, co-ordination Chemistry, anticancer, medicinal chemistry.

DMARD (Disease Modifying Anti-Rheumatic Drugs), the combination of methotrexate (MTX), sulfasalazine (SSZ) and hydroxychloroquine (HCQ) has been most effective in management of Rheumatoid arthritis (RA), a chronic inflammatory autoimmune disease. The poor solubility and/or limited penetration of these drugs present significant challenges in their topical drug delivery. An ionic liquid (IL)-based nanoemulgel of combination of these drugs was developed using a Design of Experiments approach to overcome these limitations and enhance drug delivery efficacy. Third generation Ionic liquids, known for their biocompatibility, ability to improve solubility and permeability, were synthesized by converting DMARDs, into their API-IL forms using sodium docusate through a metathesis reaction. The synthesized ILs exhibited improved solubility and stability at pH 6.3. Characterization techniques such as UV-VIS spectroscopy, FTIR, DSC, and XRD confirmed the successful synthesis and stability of the ILs. A nanoemulsion was prepared using high-pressure homogenization, achieving an optimized particle size of 22.1 nm, which was then incorporated into a nanoemulgel to facilitate targeted drug release. Additionally, in-vitro diffusion and ex vivo skin permeation studies revealed enhanced transdermal penetration, supporting the formulation's efficacy. Images of goat ear skin captured with a fluorescence microscope after 6 hrs. of treatment with Rh6G-nanoemulgel showed deep penetration while drug solution (control) only displayed fluorescence in the superficial subcutaneous Stratum Corneum (SC) layer. The nanoemulgel also demonstrated effective COX-2 (potential anti-inflammatory marker) inhibition in cell-based assays. The developed nanoemulgel demonstrated potential as a novel topical drug delivery system for rheumatoid arthritis treatment, offering enhanced solubility, permeation and localized therapeutic action.

**Keywords:** Rheumatoid Arthritis, DMARDs, Ionic liquid, Nanoemulgel.

**DEVELOPING AND EVALUATING GEMCITABINE-LOADED MPEG-PCL NANOPARTICLES FOR IMPROVED BBB TRANSPORT**

**DR. B.V. NAGARJUNA YADAV* AND DR. SATHESH KUMAR**
SCHOOL OF PHARMACY, GH RAISONI UNIVERSITY AMRAVATI, MAHARASHTRA, INDIA.

Cancer is still one of the deadliest diseases in the world, posing a serious threat to our civilization even with improvements in detection and treatment. The purpose of this research project is to formulate Methoxy Polyethylene Glycol-Poly (Caprolactone)-loaded Gemcitabine (GCB) nanoformulations and perform physicochemical characterization. The main objective of this research work is to target brain glioma cells and improve drug transportation and penetration across the blood-brain barrier (BBB). The modified nanoprecipitation process was utilized to prepare MPEG-PCL nanoparticles loaded with gemcitabine by varying drug and polymeric concentrations. Particle size, zeta potential, entrapment efficiency, drug content, and in-vitro drug release of the prepared nanoparticles (NP) were evaluated. U-87 MG cells were used to test the in vitro cytotoxicity of drug-loaded nanoparticles. When the concentration of the polymer increased, the produced nanoformulations showed a noticeable rise in particle size. The optimized nanoformulations (MPEG-PCL nanoformulations loaded with GCB) showed nanoscale particle size distribution. FTIR spectra and DSC thermograms confirm that there is no significant incompatibility between the drug and polymers. Studies using SEM, TEM, and AFM revealed that the NPs had smooth, spherical surfaces devoid of pinholes or fissures. The optimized formulation exhibits an early burst release followed by a steadier and prolonged release phase, as demonstrated by in vitro release experiments (maximum drug release). The IC50 value of the cytotoxicity of MPEG-PCL nanoformulations loaded with GCB was decreased. Hoechst 33342 dye was used in an assay for detecting apoptosis, and the results showed that the fluorescence of the apoptotic cells increased. Comparing the GCB-loaded MPEG-PCL nanoformulations to the pure drug, invasive experiments show a considerable inhibition of cell migration. In U-87 MG glial cells, the GCB-loaded MPEG-PCL nanoparticles demonstrated enhanced cytotoxic activity at lower doses than the pure drug. Therefore, MPEG-PCL nanoformulations loaded with GCB may be useful as a drug delivery vehicle for the treatment of brain cancers.

**FORMULATION AND EVALUATION OF TRANSDERMAL PATCHES LOADED ANTI-INFLAMMATORY DRUGS AND POLYMERS**

MS. APARNA BHANU KOBI AND DR. B. V. NAGARJUNA YADAV
SCHOOL OF PHARMACY, G. H. RAISONI UNIVERSITY AMRAVATI, MAHARASHTRA, INDIA.

The transdermal drug delivery system is an alternative route for the systemic drug delivery, the total about 74% of drug taken orally and are found not to be as effective as desired. To improve such character's transdermal drug delivery system was emerged drug delivery through the skin to achieve a systemic effect of a drug is commonly known as transdermal drug delivery system and differ from traditional topical drug delivery. The purpose of the research work was to formulation and evaluation of the transdermal drug delivery system Celecoxib, Nimesulide using polymers such as Poly Lactic Co-Glycolic Acid, Hydroxy Propyl Methyl Cellulose by the solvent evaporation method. The Fourier transform study revealed no physical or chemical reaction in between Celecoxib, Nimesulide & PLGA. The differential scanning calorimetry study also confirms the sharp exothermic peak at melting point of drugs and polymers. the physical appearance also studied like physical evaluation, colour, odour, taste, solubility. The prepared formulation was evaluated for different physiochemical characteristics such as, thickness, weight uniformity, surface pH determination, skin irritation, drug content. The in vitro drug release was performed using Guinea pig skin. The result of in vitro drug release study shows maximum release of 99.60% in 22 hrs. Whereas F7 shows the minimum release of 69% in 24 hrs. based on that the drug release and physiochemical values obtained the formulation F5 was considered as an optimized formulation, which shows the higher percentage of drug release of 99.60% in 22 hrs. The developed transdermal patches increase the therapeutic efficacy and reduced toxic effect of celecoxib & Nimesulide.

**Keywords:** Nimesulide, PLGA, Celecoxib, Transdermal Patches and Topical drug Delivery.

**Design And Evaluation Of Targeted Nano Carrier Systems For Site-Specific Delivery Of Anti-Cancer Drugs In Colon Cancer**

Are Pradeepthi and V Shanmugam
Research Scholar, School of Pharmacy, Mohan Babu University, Sree Sainath Nagar, Tirupati, Andhra Pradesh 517102.
Assistant Professor, Malineni Perumallu Pharmacy College, Pulladigunta, Vatticherukur, Prathipadu Road, Guntur, Andhra Pradesh 522017.
pradeepthi.a@gmail.com

Colon-specific delivery of drugs plays a crucial role in maximizing therapeutic efficacy with minimum systemic toxicity in colon cancer chemotherapy. The current research focuses on the construction of a new liposome-based nano carrier system for highly targeted delivery of 5-Fluorouracil (5-FU) and Irinotecan to the colon, thus increasing site-specific activity and decreasing off-target effects. Liposomes were designed through thin-film hydration combined with remote drug loading, with pH-sensitive polymers to provide selective release of drugs in colonic environments. Formulations were subjected to thorough physicochemical characterization through particle size analysis, zeta potential, morphology (by SEM), and encapsulation efficiency. In vitro release experiments mimicking gastrointestinal transit revealed that the optimized liposomes (size ~120 nm, zeta potential -32 mV) exhibited

ISBN: 978-81-980623-8-3

sustained and targeted release patterns, with >80% liberation of drug at colonic pH and negligible release in gastric/small intestinal conditions. HT-29 colon cancer cell line cytotoxicity assays demonstrated the significantly increased inhibition of cell growth against the free drugs, and target efficiency assays verified drug selective accumulation in colon-simulated environments. The system designed proved stable and exhibited superior drug delivery kinetics, validating its novelty and clinical significance. The sophisticated liposomal nano carrier system exhibits outstanding targeting specificity, controlled release of drugs, and promoted anti-cancer activity against colon cancer therapy, which represents a significant advancement in nanomedicine-based site-specific chemotherapy. The method presents a new, promising platform for the future of personalized and less-toxic cancer therapies.

**Comparative Evaluation Of Curcumin Formulations For Treatment Of Polycystic Ovary Syndrome**

Pooja Mallya and Shaila Angela Lewis
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal- 576104, Karnataka, India.
s.lewis@manipal.edu

Polycystic ovary syndrome (PCOS) is a multifactorial gynecological disorder affecting 5–26% of women worldwide, with nearly 75% remaining undiagnosed. It disrupts reproductive, endocrine, metabolic, and psychological functions. Current treatment approaches, including life style modifications and synthetic agents such as metformin, gliptins, and hormonal pills, address individual symptoms such as insulin resistance, anovulation, and hyperandrogenism but fail to treat PCOS holistically and are often associated with adverse effects. Phytochemicals and plant extracts have gaind attention as alternative therapies, with Curcumin (CUR) emerging as a promising phytocompound. However, its low solubility (0.66 µg/mL) and poor bioavailability (<1%) limit clinical use. This study explored two CUR formulations, a co-amorphous formulation (CAM) with Naringin (NRG) and phospholipid complex (CPLC) with Phospholipon 90H, to enhance solubility, bioavailability, and therapeutic efficacy. Molecular docking identified NRG as a potential co-former and P-glycoprotein inhibitor compared to Quercetin. CAM and CPLC prepared by quench cooling and solvent evaporation, respectively were characterized using DSC, FT-IR, PXRD, and SEM, confirming amorphous CUR an hydrogen-bonding interactions. Both formulations significantly improved solubility, dissolution, and ex-vivo permeability, with stability maintained for three months at 40 °C ± 2 °C / 75% ± 5% RH. Therapeutic efficacy was evaluated in dehydroepiandrosterone-induced PCOS rats on a high-fat diet. Both CAM and CPLC enhanced CUR bioavailability and improved reproductive and metabolic outcomes ($P<0.0001$). CAM effectively normalized estrous cycle, ovarian morphology, glucose, weight gain, and serum testosterone, while CPLC significantly improved serum lipid profiles. To conclude, both CAM and CPLC enhanced CUR's therapeutic effects, and their combined use may offer a comprehensive strategy for PCOS treatment.

**FORMULATION AND EVALUATION OF HERBAL TRANSDERMAL DRUG DELIVERY SYSTEM FOR THE TREATMENT OF RHEUMATOID ARTHRITIS**

Arya Patil
Department of Pharmacy Dr Babasaheb Ambedkar Technological University, Lonere Raigad 402103 M.H India.
Patilarya614@gmail.com

Rheumatoid arthritis (RA) is a chronic, progressive autoimmune disorder primarily affecting the peripheral joints through persistent inflammation. Conventional allopathic treatments for RA typically follow two standard therapeutic approaches; however, both are associated with notable side effects. This has led to increasing interest in safer, more natural alternatives such as Ayurvedic herbal therapies. In this study, a novel transdermal drug delivery system was developed using herbal extracts from Boswellia serrata, Cardiospermum helicacabum and Aloe barbadensis, known for their anti-inflammatory properties. The patches were prepared using the solvent casting method, incorporating the plant-based formulations into transdermal films. The developed patches were systematically evaluated for various physicochemical characteristics, including thickness, folding endurance, physical appearance, weight uniformity, moisture content, drug content, flatness, moisture uptake, surface pH, and stability. Overall, this research highlights a promising and innovative approach to utilizing transdermal drug delivery systems for herbal treatments, offering a safer and effective alternative for managing rheumatoid arthritis.

**Keywords:** Rheumatoid arthritis, Ayurvedic herbal treatment, Transdermal drug delivery, Solvent casting method, Physicochemical evaluation.

4Department of Pharmacognosy, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru – 570015, Karnataka, India

Solid lipid nanoparticles (SLNs) are attractive drug delivery systems owing to their biocompatibility and ability to enhance the solubility of poorly water-soluble drugs. In this study, noscapine (NCE)-loaded SLNs were formulated using stearic acid (SA) and glyceryl monostearate (GMS) by a modified high-shear homogenization method. The formulations were evaluated for particle size, polydispersity index (PDI), zeta potential, entrapment efficiency (EE), and in vitro drug release. The optimized GMS-based formulation (F3) exhibited a mean particle size of 195.66 ± 11. nm, a narrow PDI (0.212 ± 0.09), and high surface stability with a zeta potential of –35.74 ± 2.59 mV. It showed a high entrapment efficiency (86.77 ± 4.22%) and sustained drug release, reaching complete release within 24 hours.Analytical characterization confirmed the successful incorporation of noscapine into the lipid matrix. FTIR spectra indicated no chemical interaction between drug and excipients. DSC thermograms showed the disappearance of the characteristic melting peak of pure noscapine, suggesting molecular dispersion in the lipid. XRD patterns revealed a reduction in crystalline intensity, confirming partial amorphization and improved solubility. SEM analysis demonstrated spherical, smooth-surfaced nanoparticles with uniform morphology. These findings demonstrate that noscapine-loaded SLNs provide enhanced solubility, high stability, and controlled release, supporting their potential as an effective platform for targeted anticancer therapy.

**Keywords:** Noscapine, Solid Lipid Nanoparticles, Glyceryl Monostearate

**LANDMARK PREDICTIVE MODEL FOR THE PRECISE SOLUBILITY PARAMETER PREDICTION OF LIPIDS FOR LIPID-BASED DRUG DELIVERY APPLICATIONS**

Ryan Varghese, Pardeep Gupta
Department of Pharmaceutical Sciences, Philadelphia College of Pharmacy, Saint Joseph's University, Philadelphia, Pennsylvania, 19104, USA
ryanvarghese14@gmail.com

The determination of solubility parameters is a pivotal element in pharmaceutical preformulation and formulation, guiding the selection and optimization of excipients for drug delivery systems. Traditionally, approaches such as molecular dynamics (MD) simulations have served as the gold standard for estimating solubility metrics but suffer from significant limitations, often requiring extensive computational time (up to 25 days on CPU or 2 days on GPU) and complex force field setups, rendering them unsuitable for large-scale application. In response to these bottlenecks, this research introduces a mathematical predictive model for the estimation of Hildebrand solubility parameters (δ), a

ISBN: 978-81-980623-8-3

quantitative measure of cohesive energy density that reflects a substance's dissolution propensity premised on the principle of "like dissolves like." The model integrates electrostatic forces (δElec), van der Waals forces (δVdW), and simulated specific heat capacity, enabling precise computation of lipid excipient solubility while circumventing resource-intensive simulations. Validation using training and test sets of 76 lipids revealed outstanding performance, with an adjusted $R^2$ of 98.21%, low mean prediction error of 4.3895%, strong dataset correlation (r=0.879), and an RMSD of 1.271, underscoring both accuracy and reliability. The absence of statistical disparity between predicted and experimental results further substantiates the model's robustness. The adoption of this predictive paradigm accelerates preformulation studies, supporting the rational design of advanced lipid-based drug delivery systems, including lipid nanoparticles and self-emulsifying delivery formats—for challenging, poorly water-soluble drugs. This transformative approach promises to revolutionize pharmaceutical development by enhancing efficiency, scalability, and accessibility while maintaining scientific rigor and feasibility.

## OPTIMIZATION AND PHARMACOKINETIC EVALUATION OF GASTRORETENTIVE MUCOADHESIVE MICROSPHERES OF PROPRANOLOL HYDROCHLORIDE USING THIOLATED TRAGACANTH: A NOVEL STRATEGY FOR ENHANCED DRUG DELIVERY

Mahesh Namballa1, Rajesh E Jesudasan1, Anilkumar Adimulapu1
1 School of Pharmacy, The Assam Kaziranga University Koraikhowa, NH-37, Jorhat 785006, Assam, India

Background: Gastroretentive mucoadhesive drug delivery systems offer a promising approach to enhance the therapeutic efficacy of drugs with low bioavailability and short half-lives. The current study aims at the formulation and pharmacokinetic evaluation of propranolol hydrochloride-loaded gastroretentive mucoadhesive microspheres using thiolated tragacanth (TTG)—a chemically modified natural polymer with improved mucoadhesive capacity. Methods: TTG was prepared by esterification and characterized for thiol content, swelling ability, and mucoadhesive properties. Propranolol hydrochloride loaded microspheres were prepared employing ionic gelation with cross-linking using $CaCl_2$ and $BaCl_2$. Microspheres so prepared were characterized for particle size, drug entrapment efficacy, swelling index, and in vitro drug release profiles. Pharmacokinetic profile in Wistar rats was done to identify increases in bioavailability. Results: Thiolation of the polysaccharide resulted in 3.5-fold greater thiol levels, improving greatly the mucoadhesive character of tragacanth. Optimum microspheres were spherically shaped with excellent entrapment efficacy of 84.2 ± 2.7%. Release studies conducted under in vitro conditions indicated controlled drug release over a period of 12 hours following Korsmeyer-Peppas, indicative of non-Fickian or anomalous diffusion. Pharmacokinetic evaluation showed 2.8-fold relative bioavailability increase over the standard propranolol solution, with delayed Tmax and increased Cmax values, indicating improved systemic absorption. Conclusion: The thiolated tragacanth-based gastroretentive microspheres developed in this work showed enhanced drug retention and bioavailability, indicating their potential as a new drug delivery system for propranolol hydrochloride. This work highlights the promise of thiolated natural polymers in sustained drug delivery systems and invites further research in this direction.

## EVALUATION OF STABILITY, PERMEATION OF EXENATIDE AND ITS PULMONARY DELIVERY OPTIMIZATION WITH MANNITOL CARRIERS

Ravi Vamsi Peri and Pardeep Gupta
Department of Pharmaceutical Sciences, Philadelphia College of Pharmacy, Saint Joseph's University, Philadelphia, Pennsylvania, 19104, USA
rp10782813@sju.edu

Exenatide, a GLP-1 receptor agonist, is limited by conformational instability and permeability barriers. This study aimed to evaluate its structural stability, permeation properties, and potential for pulmonary delivery. Results from circular dichroism (CD) spectroscopy revealed that exenatide in its aqueous solution undergoes irreversible oligomerization, especially upon heating and cooling. This reported a decrease in the α-helicity from 36.3% (30 °C) to 15.5% (90 °C) and only partial recovery (19.8%) upon cooling. The corresponding increase in β-sheet content (to 21.9%) and ellipticity at 222 nm confirmed aggregation. In contrast, incorporation of sugars preserved secondary structure. Exenatide:mannitol (1:8) recovered 73.2% α-helix after thermal cycling, while trehalose (1:8) maintained 78.7%, with ellipticity ratios (R2) corroborated reduced aggregation. Franz diffusion studies demonstrated improved permeability with sugar formulations. In the presence of mucus, exenatide alone demonstrated a low permeability coefficient (P = 0.0008). However, mannitol (1:6) and trehalose (1:4) improved the permeability to P = 0.0012 and P = 0.0019, respectively. In the absence of mucus, exenatide showed poor transport (P = 0.0002), whereas mannitol (1:4) and trehalose (1:8) substantially increased permeation (P = 0.0014 and 0.0010, respectively). These findings indicate that both sugars mitigate the diffusion-retarding effect of mucus and facilitate peptide transport. To enable inhalation delivery, mannitol was engineered as a porous carrier employing spray drying. Optimized conditions (70°C outlet temperature, 2.5% solid content) yielded particles with uniform pores, high porosity (90.7%), reduced aerodynamic diameter (6.0 µm), and elevated specific surface area, favorable for deep lung deposition. Collectively, sugars stabilize exenatide, enhance mucus permeation, and engineered mannitol provides an efficient carrier for pulmonary delivery.

## DEVELOPMENT OF FORMULATION AND EVALUATION OF ANTIRHEUMATOID TOPICAL HYDROGEL WITH METHANOL EXTRACTS OF POGOSTEMON QUADRIFOLIUS AND GLOBBA WINITTI VALIDATION BY INVITRO ELISPOT CYTOKINE ANALYSIS OF TNF A INHIBITION

Ramya Madhiri, Rakesh Barik
Department of Pharmacognosy and Phytochemistry, Malla Reddy Institute of Pharmaceutical Sciences, MRV Deemed to be University, Hyderabad, India - 500014
madhiriramya2709@gmai.com

This study investigates the formulation and evaluation of topical hydrogels incorporating methanolic extracts of Pogostemon quadrifolius (MEPQ) and Globba wintii (AMEGW) for antiarthritic potential. The Method involved was extracts were incorporated into a Carbopol 940-based gel matrix. Anti-inflammatory activity was initially screened using an in vitro protein denaturation assay, where all formulations demonstrated dose-dependent inhibition. To further validate the immunomodulatory potential, an ELISPOT assay was employed to quantify cytokines (TNF-α,) in lipopolysaccharide (LPS)-stimulated PBMCs. The combination 2 % hydrogel (MEPQ+AMEGW) exhibited superior efficacy, showing reduced cytokine spot formation when compared with 2% individual extract of MEPQ and AMEGW using Diclofenac gel as Standard Statistical analysis has been performed utilizing one-way ANOVA, subsequently utilizing Tukey's post hoc test. Significance level of $p < 0.05$ has been employed to assess statistical differences. This confirms synergistic effect of the extracts and their potential as topical antiarthritic agents.

**Keywords:** Topical hydrogel, Pogostemon quadrifolius, Globba wintii, antiarthritic, ELISPOT assay, protein denaturation, cytokine profiling

## SYMBIOTIC CULTURE OF BACTERIA AND YEAST (SCOBY)-INFUSED PROBIOTIC FERMENTED PRODUCT FOR ADVANCED NUTRACEUTICAL APPLICATIONS.

Dr. Bhavana U. Jain, Dr. Sanaulla A. Tamboli, Dr. Manish S. Kondawar.
Department of Pharmaceutical Chemistry, Appasaheb Birnale College of Pharmacy, Sangli. 416416

The global demand for functional foods and nutraceuticals is steadily increasing, driven by consumer awareness of the relationship between diet and health. Among these, probiotics have attracted significant attention as live microorganisms that provide health benefits when consumed in adequate amounts. They play a vital role in improving gut health, enhancing immunity and preventing various metabolic and

ISBN: 978-81-980623-8-3

infectious diseases. Fermented foods are considered an ideal delivery system for probiotics as they enhance microbial stability, viability and bioavailability. Beyond gut health, improving haemoglobin levels is a critical nutritional requirement, particularly for populations at risk of anaemia. Moringa oleifera extract, recognized for its high nutritional value, is an excellent source of iron, vitamin C, flavonoids and polyphenols. These bioactive components synergistically promote haemoglobin synthesis, red blood cell formation and oxidative stress reduction, thus supporting effective anaemia management. The present invention introduces a dual-functional nutraceutical that integrates probiotic fermentation with Moringa oleifera extract. This novel formulation aims to improve gut microbiota composition while simultaneously enhancing haemoglobin levels. The combined effects include increased antioxidant potential, improved nutrient absorption, immune system modulation and prevention of anaemia.

**Keywords:** SCOBY, Moringa oleifera, probiotics, iron-deficiency anaemia

**HIGH-PERFORMANCE HYBRID NANOFILLERS FROM ZIRCONIA-COATED, Γ-MPS FUNCTIONALIZED HALLOYSITE NANOTUBES**

Rakshitha N Hemadri and Fatima S Dasankoppa
Department of Pharmaceutics, KLE college of Pharmacy, Hubballi, Karnataka, India 580031
yencharlarakshitha@gmail.com

This study developed advanced zirconium dioxide (ZrO2)-reinforced halloysite nanotube (HNT) nanofillers with improved dispersion, interfacial bonding, and thermal stability for low-shrinkage, light-curable dental composites. Initially, pristine HNTs (PHNTs) were functionalized with γ-methacryloxypropyltrimethoxysilane (γ-MPS), confirmed by FT-IR peaks at 1492.34 cm-1 ((CH2)3 scissoring), 2921.05 cm-1 (C-H stretching), and 1708.62 cm-1 (C=O stretching), along with increased d-spacing from 7.38 Å to 7.66 Å in XRD, indicating successful surface modification. Functionalized HNTs (FHNTs) showed smoother surfaces, reduced aggregation, improved dispersion stability (zeta potential -40.07 Mv (FHNT) -33.35 mV for (PHNTs), and enhanced thermal stability (TGA weight loss -1.99 mg (PHNT) -2.44 mg (FHNT)). In the second stage, FHNTs were coated with ZrO2 nanoparticles via probe sonication, yielding Zr-FH-PS nanofillers with sharper Zr-O FT-IR peaks (427 & 462 cm-1), monoclinic ZrO2 XRD reflections, and increased crystallite size (269 nm). FE-SEM/EDX revealed a uniform rough-textured coating with Zr content (10.0 wt%), while HR-TEM showed well-distributed at 20-40 nm coating of ZrO2 particles on to the outer FHNT. TGA confirmed superior thermal stability, with weight loss reduced to -0.56 mg. The combination of γ-MPS functionalization and probe sonication enabled stronger surface grafting, better nanoparticle distribution, and improved interfacial bonding. These enhancements in crystallinity, dispersion, and stability make Zr-FH-PS a promising nanofiller for dental composites, expected to improve mechanical strength, reduce polymerization shrinkage, and enhance long-term durability in clinical applications.

This study presents EC-based microspheres and HPMC are used to create a patient-friendly, regulated delivery system by solvent evaporation. Through the preservation of vitamin D3, stability, bioavailability, and support for bone health, it improves the management of periodontitis. Important formulation parameters were optimized, including drug-to-polymer ratio, polymer concentration, and emulsification speed. Particle size, surface morphology, drug loading, encapsulation efficiency, zeta potential, polydispersity index, and in vitro release were all evaluated for the microspheres. The FESEM examination showed smooth-surface morphology of microspheres within 100 micrometer range. The average particle size was found to be 611.6nm. Studies conducted in vitro revealed diffusion-controlled sustained release of 2.43% in 12 hr. and zeta potential was found to be -19.1 mV. The solvent evaporation approach was used in this study to successfully create vitamin D3-loaded microspheres using HPMC and EC. Smooth, spherical particles with excellent encapsulation of 84%, indicating effective entrapment of Vitamin D3 within the polymer matrix. Effective microspheres with desired physicochemical features were produced by optimising the formulation parameters. A diffusion-controlled sustained release profile was validated in vitro, enhancing the stability and bioavailability of vitamin D3. Better patient compliance in the treatment of periodontitis is encouraged by this regulated delivery method, which also increases therapeutic potential.

**Keywords:** Vitamin D3, microspheres, periodontitis HPMC, EC.

rautneha123@gmail.com

Curcumin nanoparticles and metalloantibiotics represent promising alternatives to conventional antibiotics due to their potent antimicrobial activity. In this study, curcumin biofunctionalized and cefixime nanoparticles incorporating silver, palladium, cadmium, nickel, and zinc were synthesized via a one-pot, two-step green method and extensively characterized. Color and pH variations confirmed metal ion reduction, while UV-vis and FTIR analyses indicated nanoparticle formation. The synthesized particles displayed sizes of 25–100 nm with uniform distribution (PDI 0.2–0.4) and high stability (zeta potential −25 to −36 mV). FESEM revealed spherical, square, and disc-shaped nanoparticles, while EDX and XRD confirmed elemental composition and crystalline structure respectively. ICP-OES quantified silver content in the formulations. Antibacterial evaluation against Escherichia coli, Klebsiella pneumoniae, and Staphylococcus aureus showed enhanced inhibition by metallic nanoparticles compared to parent drugs. Minimum inhibitory concentration assays revealed markedly lower MIC values for curcumin biofunctionalized silver nanoparticles and drug-silver nanoparticle hybrids, demonstrating synergistic antibacterial effects. Moreover, efflux pump inhibition assays suggested improved intracellular drug retention. In vivo acute toxicity evaluation in rats showed no significant histopathological changes in major organs, indicating biosafety at tested doses. Collectively, these results highlight the synergistic antimicrobial potential of curcumin and antibiotic-conjugated metallic nanoparticles, offering a safe and effective nanoformulation strategy against multidrug-resistant pathogens.

**Keywords:** Curcumin nanoparticles, Metalloantibiotics, Silver nanoparticles, Green synthesis, Antibacterial activity, Efflux pump inhibition, Cefixime, Toxicity study.

**DEVELOPMENT, EVALUATION AND STABILITY STUDIES OF SILVER NANOPARTICLE OF MEROPENEM AGAINST MDR MICROORGANISMS**

Pankaj Pachghare*, Akash Gawande, Neha S. Raut, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Maharashtra 441002

Nanotechnology-based drug delivery systems are increasingly recognized as a powerful approach to overcome the limitations of conventional antibiotics in the fight against resistant pathogens. In this study, Meropenem-conjugated silver nanoparticles (Mero-Ag NPs) were synthesized via probe sonication, aimed at restoring and enhancing antibacterial activity against multidrug-resistant strains. UV-Vis spectroscopy confirmed nanoparticle formation through a characteristic absorption peak shift compared to Meropenem alone, while FTIR analysis revealed functional group modifications indicating successful conjugation. X-ray diffraction (XRD) demonstrated the crystalline structure of the nanoparticles, and field emission scanning electron microscopy (FESEM) showed spherical morphology with an average diameter of 121 nm. Energy-dispersive X-ray spectroscopy (EDX) validated their elemental composition, and stability testing indicated moderate zeta potential, supporting colloidal integrity. Antibacterial studies against Klebsiella pneumoniae, Escherichia coli, Staphylococcus aureus and Acinetobacter baumannii revealed superior performance of Mero-Ag NPs compared to free Meropenem, with significantly reduced

ISBN: 978-81-980623-8-3

minimum inhibitory concentration (MIC) values and enhanced biofilm disruption. Acute toxicity evaluations confirmed their biosafety. Collectively, these results suggest that Meropenem-loaded silver nanoparticles represent a promising nanomedicine-based strategy for combating multidrug-resistant bacterial infections and strengthening conventional antibiotic therapies.

**Keywords:** Meropenem, Silver nanoparticles (AgNPs), antibacterial, Antimicrobial resistance, Multidrug resistance

**DEVELOPMENT, VALIDATION, AND PHARMACOKINETIC APPLICATION OF A STABILITY-INDICATING LC-MS/MS METHOD FOR QUANTIFICATION OF DACOMITINIB IN RAT PLASMA**

P. Vivek Sagar, Manisha, Lahari Nikitha,
Department of Pharmaceutical Analysis, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya Secunderabad, Telangana

A sensitive, selective, and robust liquid chromatography-tandem mass spectrometry (LC-MS/MS) method was developed and validated for the quantification of Dacomitinib in rat plasma, employing Entrectinib as an internal standard. Dacomitinib, a second-generation irreversible epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor, is used for first-line treatment of metastatic non-small cell lung cancer. The chromatographic separation was achieved on an Inertsil ODS C18 column (150 mm × 4.6 mm, 3.5 µm) using a mobile phase composed of acetonitrile and triethylamine buffer (pH 2.5) with a flow rate of 1.0 mL/min and a total runtime of 5 minutes. Detection was carried out in positive ion mode using multiple reaction monitoring (MRM) with transitions m/z 560.28→212.36 for Dacomitinib and m/z 560.37→193.65 for Entrectinib. The assay exhibited excellent linearity over the concentration range 5–100 ng/mL with a correlation coefficient ($r^2$) of 0.9996. Precision and accuracy across quality control levels met USFDA guidelines. Stability studies, including bench-top, freeze-thaw, short-term, and long-term storage, confirmed the robustness of the method. The method was successfully applied to a pharmacokinetic study in rats following oral and intravenous administration of Dacomitinib. This validated LC-MS/MS method demonstrates suitability for rapid and reliable quantification of Dacomitinib in plasma, facilitating preclinical pharmacokinetic evaluations.

**Keywords:** Dacomitinib, LC-MS/MS method, Pharmacokinetic study, Rat plasma, Method validation

**"DESIGN, DEVELOPMENT AND CHARACTERIZATION OF MUCOADHESIVE BILAYER TABLETS OF ACARBOSE"**

Mr. Vinayraj Paramshetty1, Dr Nagendra kumar2 and Mr. Satish V. Udbale3
SVET'S College of Pharmacy, Humnabad.
vparamshetty@gmail.com

Among the various routes of drug delivery, the oral route is perhaps the most preferred by patients and clinicians alike. However, pre oral administration of drugs has disadvantages, such as hepatic first-pass metabolism and enzymatic degradation within the gastrointestinal tract (GIT). So, there has been a growing interest in the use of delivery of therapeutic agent through various transmucosal routes to provide a therapeutic amount of drug to the proper site in body to promptly achieve and then maintain the desired concentration. In the present work buccal bilayer tablets of Acarbose were prepared by direct compression method by using polymers HPMC K4M and HPMC K15M.The prepared tablets were evaluated for physical parameters like appearance, hardness, thickness, weight variation, friability, swelling index and surface pH; biological parameter-mucoadhesive strength; and other parameters such as drug content uniformity, in vitro release, short-term stability and drug excipient interactions (FTIR). Among ten formulations, the formulation BTA151 containing HPMC K15M was found to be promising, which showed t25%, t50% and t70% values of 1.12, 4.24 and 5.48 h respectively and in vitro drug release of 93.28% in 8 h along with satisfactory bioadhesion strength (6.40 g). Stability studies on the promising formulation indicated that there are no significant changes in drug content and in vitro dissolution characteristics ($p<0.05$). Infrared-spectroscopic studies indicated that there are no drug-excipient interactions. The prepared buccal bilayer tablets of Acarbose could stay in the buccal for a longer period of time, which indicate a potential use of buccal tablets of Acarbose for treating of type 2 diabetes.

**Keywords:** Buccal bilayer tablets; Acarbose; Carbopol 934p; Hydroxy propyl methyl cellulose; Bioadhesive strength; In vitro dissolution.

**DESIGN, DEVELOPMENT AND EVALUATION OF DUAL DRUG-LOADED NOVEL DRUG DELIVERY SYSTEM FOR THE EFFECTIVE TREATMENT OF HEAD AND NECK CANCER**

Mohit Angolkar*, Sharanya Paramshetti, Asha Spandana K M, Riyaz Ali M Osmani
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, S.S. Nagar, Mysuru, Karnataka, India-570015.
mohitangolkar11@gmail.com

Head and neck cancers (HNC) are among the most prevalent malignancies affecting the mucosal linings of the oral cavity, larynx, and pharynx. Despite the availability of multimodal treatment approaches—surgery, chemotherapy, immunotherapy, radiation therapy, and targeted therapy—current approaches are often limited by systemic toxicity, poor drug bioavailability, and high recurrence due to metastasis. As per the Global Cancer Observatory, over 947,000 HNSCC cases and 482,000 associated mortalities were observed globally, emphasizing the urgent need for more effective and safer therapeutic alternatives. The current study explores a novel targeted drug delivery using a Lipid Polymer Hybrid Nanoparticle (LPHNP) loaded with two anticancer drugs for HNC treatment. Two chemotherapeutic agents, each targeting distinct oncogenic pathways, were encapsulated to achieve synergistic anticancer activity. Nanoparticles were formulated using the thin-film hydration process and optimized through a Box-Behnken (BBD) statistical design. Characterization using SEM and TEM confirmed spherical morphology and desirable particle size. The optimized nanoparticles exhibited a mean particle size within acceptable limits and a high zeta potential, indicating stability. Entrapment efficiencies of the two drugs were 83.38% and 86.29%, respectively. In vitro release studies demonstrated a biphasic pattern with sustained drug release and prolonged retention, while HET-CAM assays confirmed the non-irritant nature of the formulation. Additionally, the system showed high biocompatibility and potential for tumor-specific accumulation. The results suggest that dual drug-loaded LPHNPs can significantly improve therapeutic outcomes by enhancing drug stability, targeting efficiency, and safety. The proposed system is anticipated to improve drug stability, tumor-specific accumulation, and controlled release, thereby enhancing therapeutic outcomes in HNC. This research offers a potential advancement in precise, effective, and safer cancer therapy.

**"EVALUATION OF ANTIOXIDANT POTENTIAL OF MORINGA OLEIFERA LEAF EXTRACTS OBTAINED BY DIFFERENT EXTRACTION TECHNIQUES"**

Ravi Hashappa1, Nagendra kumar2, Gove Vinod Sidram3
Svets College Of Pharmacy, Humnabad.
guttedarravo03@gmail.com

The present study investigates the antioxidant potential of Mooring oleifera leaf extracts obtained through various extraction techniques including maceration, reflux condensation, soxhlet extraction and sonication extraction. The extracts were evaluated for their total phenolic, tannin and flavonoid content along with antioxidant activity using DPPH assays. Results indicated that extraction technique significantly influenced the yield and bioactive compound content. Among the methods tested, soxhlation extraction yielded the highest concentration of phenolics and flavonoids, correlating with superior antioxidant activity. Refluxation shows highest antioxidant activity and sonication shows least antioxidant activity. The study highlights the importance of selecting appropriate extraction methods to maximize the recovery of antioxidant constituents from Moringa oleifera leaves.

**Keywords:** Moringa oleifera, Extraction and Antioxidant activity.

**FORMULATION AND EVALUATION OF RIZATRIPTAN LOADED NANOSUSPENSION**

ISBN: 978-81-980623-8-3

Dr. Shripathy D, Dhanya Jayantha Shastry*, Shwetha Munda*, Rohith Menon*
Department of Pharmaceutics, Srinivas College of Pharmacy, Valachil, Post Farangipete, Mangalore-574143, Karnataka, India

Rizatriptan, a selective 5-hydroxytryptamine (5-HT) 1B/1D receptor agonist, is widely used for migraine treatment; however, its therapeutic efficacy is often limited by poor aqueous solubility and variable bioavailability. Enhancing its dissolution rate could improve clinical outcomes. This study aimed to develop and evaluate a nanosuspension of Rizatriptan to address these limitations and enhance its diffusion rate and potential bioavailability. Eight nanosuspension formulations were prepared using the precipitation–ultrasonication method, with variations in organic solvents (methanol and ethanol). Poloxamer 407 was used as a non-ionic surfactant, oleic acid as a penetration enhancer, and stearic acid as a stabilizer. All formulations were characterized for particle size, drug content, entrapment efficiency, and in-vitro diffusion. Among these, formulation F3 exhibited superior performance, achieving a drug content of 85.50%, entrapment efficiency of 80.78%, particle size of 316 nm, and cumulative drug release of 82.77% over 8 hours using a Franz diffusion cell. These results suggest that nanosuspension formulation could be a promising strategy to improve the therapeutic potential of Rizatriptan.

**Keywords:** Rizatriptan, Nanosuspension, Migraine.

**PC-330**

## FABRICATION AND EVALUATION OF BIODEGRADABLE GATIFLOXACIN-LOADED ORTHOPEDIC IMPLANTS FOR OSTEOMYELITIS TREATMENT

Khushi Barahate , Dr. Tirupati Rasala, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

Osteomyelitis, a severe complication of open fracture management, often necessitates prolonged antibiotic therapy. Conventional high-dose systemic antibiotics are associated with side effects and extended hospitalization. This study focuses on developing a biodegradable orthopedic implant capable of sustained drug release for at least six weeks at concentrations above the minimum inhibitory concentration (MIC). Polylactide-co-glycolide (PLGA) and polycaprolactone (PCL) were employed as biodegradable carriers, with gatifloxacin—an effective broad-spectrum fluoroquinolone—serving as the antimicrobial agent. Implants were fabricated using an injection molding technique, ensuring uniform drug distribution. Formulations underwent dimensional analysis, hardness testing, drug content determination, sterility evaluation, in-vitro release studies, and surface morphology assessment via scanning electron microscopy. The optimized formulation (F3) demonstrated a hardness of 8.47 kg/cm², drug content of 96.89%, and uniformity across samples. In-vitro studies revealed sustained drug release, with 91% of gatifloxacin released over 55 days. SEM analysis indicated smooth surfaces prior to release, transitioning to porous structures post-release due to drug dissolution. The combination of PLGA and PCL facilitated controlled degradation, maintaining therapeutic drug levels while eliminating the need for surgical implant removal. The residual PCL scaffold provided mechanical support and promoted bone cell growth after PLGA degradation. These findings suggest that gatifloxacin-loaded PLGA-PCL composite implants offer a promising localized delivery system for osteomyelitis treatment, combining prolonged antimicrobial action, biodegradability, and adequate mechanical strength for load-bearing applications. This approach reduces systemic side effects, minimizes surgical interventions, and enhances patient recovery outcomes in orthopedic infection management.

**Keywords:** Implant, beads, PLGA, PCL, gatifloxacin, osteomyelitis, biodegradable implant, sustained drug release, orthopedic infection, local antibiotic delivery, polymer composite, injection molding

**PC-331**

## STUDIES ON SIMVASTATIN-LOADED SELF-NANOEMULSIFYING DRUG DELIVERY SYSTEM (SNEDDS) INVOLVING ANTI-ENDOMETRIOTIC & ANTI-INFLAMMATORY EFFECTS IN HUMANISED ENDOMETRIOTIC RAT MODEL

Payel Chakraborty1, Amoolya Sree1, and Tamilvanan Shunmugaperumal1*
1National Institute of Pharmaceutical Education and Research, Guwahati, Assam, India
tamilvanan1@yahoo.co.in

Endometriosis is a chronic inflammatory gynaecological condition characterised by the growth of tissue resembling the endometrium (inner tissue of the uterus) outside the uterine cavity, and it is most associated with pelvic pain and infertility. Using invasive (laparoscopy) and non-invasive (hormonal therapy/painkillers) approaches results in suboptimal outcomes in conjunction with adverse effects and endometriosis recurrence. Simvastatin, a HMG-CoA reductase inhibitor (statins), possesses pleiotropic properties, and it belongs to BCS Class IIa, meaning that it dissolves more rapidly in basic medium. This work explores the feasibility of simvastatin-loaded SNEDDS for use in the treatment of endometriosis. The formula of the pre-emulsion concentrate of drug-loaded SNEDDS was systematically optimised using the Quality by Design approach. The optimised diluted pre-emulsion concentrate of simvastatin-loaded SNEDDS achieved values of 45.1 secs self-emulsification time, 176.17 nm mean particle size, -10 mV zeta potential, and 0.318 polydispersity index. The female SD rats were intraperitoneally injected with endometriotic tissues collected from endometriotic women to induce endometriosis. After oral administration of simvastatin-loaded SNEDDS into disease-induced rats, a remarkable improvement was observed in the collected uterine, ovarian, and peritoneal tissues analysed by H&E staining and immunohistochemistry. Moreover, results from ELISA /colorimetric assays assessing anti-endometriotic markers (VEGF, TNF-α), diagnostic indicators (MMP-2,9 and TIMP-1,2), and inflammatory parameters ($Ca^{2+}$, NO, PGE2, and IL-8) in the plasma separated from the blood of treated rats further confirmed the therapeutic effectiveness of the drug-loaded SNEDDS compared to the drug solution alone in managing the endometriosis in humanised endometriotic rat model.

**Keywords:** Endometriosis, quality by design, simvastatin, SNEDDS, Sprague Dawley rats

## SYSTEMATIC OPTIMIZATION, IN VITRO CHARACTERIZATION, AND IN VIVO EVALUATION OF RUTIN HYDRATE-LOADED FENUGREEK SEEDS-GENERATED EDIBLE PLANT-DERIVED EXOSOME-LIKE NANOPARTICLES

Amoolya Sree1, Payel Chakraborty1 and Dr. Tamilvanan Shunmugaperumal1#
1 Department of Pharmaceutics, National Institute of Pharmaceutical Education and Research, Guwahati, India
amoolyasree@gmail.com

Primary dysmenorrhea (PD) is a widespread and debilitating condition affecting millions of women worldwide, characterized by intense menstrual pain. This study explores the potential of using fenugreek seeds, (having the endogenously present trigonelline) as a source for developing edible plant-derived exosome-like nanoparticles (EPDENs) to alleviate PD-related pain. EPDENs were formulated using polyethylene glycol 6000 (PEG 6000) as a crowding agent and were systematically optimized through a quality-by-design approach. The optimized EPDENs formulation demonstrated favorable physicochemical characteristics, including a particle concentration of $6.4 \times 10^{10}$ particles/ml, mean particle size of 114.1 ± 0.508 nm, protein content of 8.62 ± 0.50 mg/ml, trigonelline concentration of 107.57 ± 1.80 µg/ml, RNA content of 56.826 ± 0.749 ng/µl, and zeta potential of -21.9 ± 0.208 mV. Rutin hydrate, a flavonoid glycoside with known anti-inflammatory properties, was successfully incorporated into the EPDENs using the freeze–thaw method, achieving an entrapment efficiency of 32.91 ± 1.33%. The incorporation was confirmed through X-ray diffraction (XRD), differential scanning calorimetry (DSC), and scanning electron microscopy (SEM). In vitro release studies showed cumulative percentage release values of 76.77 ± 0.27% for rutin hydrate and 44.75 ± 0.49% for trigonelline under different pH conditions. Cellular uptake studies revealed efficient internalization of coumarin 6-tagged, rutin hydrate-loaded EPDENs in RL95-2 uterine cells. Analgesic efficacy was evaluated through writhing response reduction in PD-induced mice, demonstrating that oral rutin hydrate-loaded EPDENs were as effective as aspirin. Furthermore, treatment significantly modulated prostaglandin levels by reducing $PGF_2\alpha$ and increasing $PGE_2$, thereby lowering the $PGF_2\alpha/PGE_2$ ratio. These findings suggest that rutin hydrate-loaded fenugreek-derived EPDENs as a promising natural alternative for PD pain management.

**BENZIMIDAZOLE SUBSTITUTED INDOLE ACETAMIDE DERIVATIVES AS POTENTIAL ANTI- INFLAMMATORY AGENTS: A COMPREHENSIVE STUDY OF VIRTUAL SCREENING, SYNTHESIS, AND BIOLOGICAL ACTIVITY**

Dr. M. Vijaya bhargavi, Chencharam Tulasi
RBVRR Women's College of Pharmacy, Hyderabad

This study investigates the potential of benzimidazole substituted indole acetamide derivatives as novel anti-inflammatory agents through a multifaceted approach encompassing virtual screening, synthesis, and biological evaluation. Virtual screening using computational tools identified lead compounds based on their interaction with key inflammatory targets. Subsequent synthesis of the identified derivatives were achieved via efficient methodologies and characterized using spectroscopic techniques. Structure-activity relationship (SAR) analysis provided insights into the structural features essential for potency and selectivity. The findings highlight benzimidazole substituted indole acetamides as promising candidates for further development as therapeutic agents against inflammatory diseases.

**Keywords**: Benzimidazole, virtual screening, anti-inflammatory, structure activity relationship, indole.

**TELEHEALTH WEARABLE SENSORS UTILIZING EMERGING MATERIALS AND NANOARCHITECTONICS**

Authors: Prajakta Durge, Dr.Tirupati Rasala, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

Wearable sensors have emerged as transformative tools in telehealth, enabling continuous, real-time monitoring of physiological and biochemical markers for early disease detection and personalized healthcare. Recent innovations leverage two-dimensional (2D) materials—such as graphene and transition metal carbides/nitrides (MXenes)—which offer exceptional flexibility, mechanical stability, and high sensitivity. These properties facilitate the creation of lightweight, skin-conformable devices capable of accurately tracking vital signs including body temperature, arterial oxygen saturation, respiratory rate, pulse, and muscle fatigue. This review examines five principal categories of wearable sensors—pressure, strain, electrochemical, optoelectronic, and temperature—highlighting their sensing mechanisms, integration approaches, and healthcare applications. Examples include graphene-based wrist-mounted pulse monitors, $Ti_3C_2$ MXene-based respiration masks, and multifunctional composite sensors for simultaneous strain, temperature, and heartbeat measurement. While these technologies show substantial promise for improving telehealth services, challenges remain in ensuring device stability under environmental stresses, developing flexible power solutions, achieving cost-effective mass production, and enhancing multi-parameter sensing accuracy. Furthermore, data privacy and secure wireless transmission are critical considerations for clinical adoption. The COVID-19 pandemic accelerated the adoption of wearable health technologies, underscoring their role in remote patient monitoring and health management during restricted physical access to healthcare facilities. Future research should focus on scalable, low-cost fabrication methods, novel 2D material architectures, and integration with advanced data analytics to enable predictive diagnostics. With sustained innovation, 2D-material-based wearable sensors are poised to redefine healthcare delivery, offering accessible, reliable, and continuous monitoring to support proactive and personalized medicine.

**Keywords:** Wearable sensors, 2D materials, telehealth, remote health monitoring, graphene, MXenes ($Ti_3C_2$), pressure sensors, strain sensors, electrochemical biosensors, optoelectronic sensors, temperature sensors

**FORMULATION AND EVALUATION OF HYDROGEL-BASED TRANSDERMAL PATCH OF A SELECTED ANTIHYPERTENSIVE AGENT**

Athira B Nair, Sr. Daisy P A, Rinu Ramesh M R
Department of Pharmaceutics, St.Joseph's College of Pharmacy, Cherthala, Kerala,
India-688524.
Athira.bnair3725@gmail.com

Transdermal drug delivery systems (TDDS) are an emerging approach to controlled drug administration, designed to deliver medication through the skin at a fixed and predictable rate. Hydrogels, which are networks of hydrophilic polymers, can hold a large amount of water without losing their structural form. In transdermal patches, hydrogels not only offer a soothing, cooling sensation on the skin but also improve patient comfort compared to traditional patches. They are valued for biocompatibility, mechanical strength, reproducibility, and biodegradability. In this study, hydrogel-based patches of Losartan potassium were prepared using the solvent evaporation method. Polyvinyl alcohol was used as the base polymer, while chitosan, maleic anhydride (as a cross-linking agent), and propylene glycol (as a plasticiser) were added in different concentrations. Six different formulations were developed and tested for physical and chemical characteristics such as appearance, thickness, weight uniformity, tensile strength, swelling ability, and surface pH. Drug entrapment efficiency and in-vitro skin permeation studies were also performed, yielding satisfactory results. Among all formulations, F5 was identified as the most promising, showing superior physicochemical properties, maximum drug entrapment, and highest drug release. The Higuchi plot for F5 displayed the highest regression value, indicating that diffusion is a key mechanism of drug release.

**Keywords**: Losartan potassium; Chitosan; Polyvinyl alcohol; Maleic anhydride; Propylene glycol.

**TARGETED DRUG DELIVERY USING LIGAND-CONJUGATED SLNS FOR PCOS: A NOVEL THERAPEUTIC APPROACH**

Shuvashree Meher1, Chandan Kumar Brahma2, Rajeswari Saripilli3
Department of Pharmaceutics, School of Pharmacy & life Sciences, Centurion University of Technology and Management, Bhubaneswar, Odisha, India- 752050.
shuvashree.meher@cutm.ac.in

Polycystic Ovarian Syndrome (PCOS) is a complicated endocrine illness that affects women of reproductive age. It is characterized by hormonal imbalance, insulin resistance, and ovarian dysfunction. The effectiveness of conventional medicines is frequently limited by their poor bioavailability, non-specific medication distribution, and side effects. The purpose of this research is to determine if ligand-conjugated solid lipid nanoparticles (SLNs) can enhance therapeutic results in polycystic ovary syndrome (PCOS) by acting as a targeted medication delivery mechanism. This nanocarrier platform aspires to improve drug bioavailability, reduce systemic toxicity, and overcome physiological obstacles by facilitating targeted delivery to ovarian tissues. Surface functionalization with ovarian-specific ligands, such as FSH-receptor-targeting peptides, followed the formulation of SLNs utilizing high-shear homogenization and ultrasonication procedures. The size, zeta potential, entrapment efficiency, drug release kinetics, and ligand conjugation efficiency of the nanoparticles were all measured. Animal models of polycystic ovary syndrome were used to evaluate cellular absorption in vitro and ovarian targeting efficacy in vivo. When contrasted with non-targeted formulations, the ligand-conjugated SLNs showed much better ovarian tissue absorption, regulated drug release, and increased stability. Hormonal profiles, ovarian shape, and insulin sensitivity were all significantly improved in preclinical mice treated with ligand-guided SLNs. By enhancing medication localization, decreasing side effects, and tackling the multifactorial character of PCOS, ligand-conjugated SLNs provide a potential targeted treatment approach. Further clinical exploration is warranted by this unique method, which presents avenues for tailored nanomedicine in reproductive health.

**Keywords:** PCOS, solid lipid nanoparticles, targeted drug delivery, ligand conjugation, ovarian targeting

**FORMULATION DEVELOPMENT OPTIMIZATION AND CHARACTERIZATION OF LIPOSOMAL DRUG DELIVERY SYSTEM TO IMPROVE KINETIC PROFILE OF SELECTED ANTI-CANCER DRUG**

RLC.Sasidhar and S.Vidyadhara
Department of Pharmaceutics, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences, Chowdavaram, Guntur, Andhra Pradesh, India – 522019.
drsasidhar82@gmail.com

ISBN: 978-81-980623-8-3

In the current research a liposomal drug delivery system for the anti-cancer drug Melphalan, with the goal of improving its kinetic profile and therapeutic efficacy was formulated using various techniques and excipients. Trails were conducted optimize the liposomal formulation parameters, such as particle size, encapsulation efficiency, and drug release profile, using statistical and experimental methods. The prepared formulations were characterized in terms of its physicochemical properties, stability, and in vitro release kinetics. In order to verify the presence of liposomes in the lyophilized powder and to further investigate their surface morphology, the MLs were submitted to TEM examination. In the reconstituted solution of lyophilized powder, TEM imaging indicated the presence of spherical, uniformly dispersed liposomes. The release of Melphalan was studied in PBS pH 7.4. In vitro release studies showed that Melphalan released more slowly in PBS pH 7.4 but exhibited accelerated release in acidic conditions (PBS pH 5.8). This indicates that liposomes can offer controlled and sustained drug release with enhanced rates in acidic environments. The study successfully characterized Melphalan and developed optimized liposomal formulations. Key parameters for formulation were identified, leading to stable liposomes with improved drug encapsulation.

**Keywords**: Melphalan, Liposomes, lyophilization.

**DEVELOPMENT OF COW URINE DISTILLATE FORMULATIONS - A NUTRACEUTICAL APPROACH**

MR. GAURAV RAMESH TATHOD AND MR. SUHAS DHASWADIKAR
SCHOOL OF PHARMACY, G.H. RAISONI UNIVERSITY AMRAVATI, MAHARASHTRA.

Because of the current pandemic crisis and growing emphasis on total health, nutraceuticals are becoming more and more important. Nutraceuticals comprise goods that support immune system health and illness prevention. In Ayurveda, cow urine is a key medicinal drink used for therapeutic purposes. Nutraceuticals are becoming more and more significant due to the ongoing pandemic crisis and the increased focus on overall health. Nutraceuticals are products that promote the health of the immune system and the prevention of disease. Cow urine is an important medicinal beverage used for therapeutic purposes in Ayurveda. The Rigveda (10/15) compares CU to nectar. According to Charak (sloka-100) and Susruta (45/221), CU has a number of health advantages. These advantages include the potential to treat skin problems like vitiligo, reduce weight, reverse some cardiac and renal conditions, and relieve indigestion, stomach-aches, diarrhoea, edema, jaundice, anaemia, and haemorrhoids. Fresh cow urine and cow urine distillate undergo preliminary screening for nutritional and trace elements. Many formulations, including liquid, solid, and semisolid ones, are created and successfully tested. Five of the eleven liquid formulations that are prepared are chosen based on a variety of criteria, including stability and odour. A powder is made in solid formulation. A design professional assisted in the creation of the batches. Jelly is made in a semisolid dose form. All formulations underwent successful preliminary nutritional screening and trace element analysis. A variety of formulations, including liquid, solid, and semisolid ones, are effectively created and assessed. Stability investigations and odour masking of liquid formulations are completed successfully. No. 4 among these formulations has a nice smell and good stability. Every formulation that has been produced is suitable for oral ingestion. With a sufficient amount of trace elements, the produced formulations can be useful as nutraceuticals in terms of nutritional value.

**Keywords:** Cow Urine, Nutraceuticals, Nutritional Value and Trace Elements.

**PC-339**

**FORMULATION AND EVALUATION OF SOLID SELF-MICRO EMULSIFYING DRUG DELIVERY SYSTEM FOR ANTIDIABETIC ACTIVITY OF CASSIA TORA LINN.**

MS. PRANAY RAUT AND MR. SUHAS DHASWADIKAR
SCHOOL OF PHARMACY, G.H. RAISONI UNIVERSITY AMRAVATI, MAHARASHTRA.

Poor bioavailability of Cassia tora extract due to its gastric instability and low aqueous solubility limits its clinical application. The objective of present work was to formulate the solid self-micro-emulsifying drug delivery system (SMEDDS), to improve its bioavailability and solubility and stability for antidiabetic activity of cassia tora. Prior formulation pharmacognostic study of plant was done including morphology, microscopy, phytochemical screening revealing the presence of carbohydrates, proteins, amino acids, steroids, saponins, flavonoids, tannins, phenols, and in Cassia tora extracts. physicochemical parameter, quantitative estimation, in vitro antioxidant study, chromatographic fingerprinting including TLC and HPTLC was done. first prepare liquid SMEDDS including pre formulation solubility study, construction of pseudo ternary phase diagram of 3 ratio i.e 2:1, 3:1,and 4:1 in this the 3:1 ratio reveals the larger emulsification area than other 2 ratio .the thermodynamic stability study was done reveals that there is no any phase separation , creaming cracking is observed. Liquid SMEDDS was then convert it into solid SMEDDS by using adsorption method in this the microcrystalline cellulose was used as a adsorbent. The invitro drug release was carried out, the characterization of solid SMEDDS was FTIR, XRD, and SEM was done the FTIR ensures that our extract was completely encapsulated. Antidiabetic and histopathological studies on experimental rat revealed promising hypoglycemic activity of SMEDDS which sought for its ability to protect cassia tora extract in the stomach. By doing histopathology it reveals that the formulation has better tissue recovering ability than the cassia tora extract.

**Keywords:** Cassia Tora, Antidiabetic Activity, SMEDDS, HPTLC and Antioxidant Study.

**FORMULATION AND EVALUATION OF A TIME-DEPENDENT DRUG DELIVERY SYSTEM FOR ASTHMA THERAPY**

MS. DIPTI NICHIT AND MS. KETAKEE NICHAT
SCHOOL OF PHARMACY, G.H. RAISONI UNIVERSITY AMRAVATI, MAHARASHTRA.

The objective of this study was to design and evaluate a single-unit, time-controlled oral pulsatile drug delivery system of salbutamol sulphate for the prevention of nocturnal asthma attacks. The system was designed to release the drug after a predetermined lag time of six hours, coinciding with the early morning peak in asthma symptoms. Fast-dissolving core tablets were formulated using various super disintegrants, including sodium starch glycolate, croscarmellose sodium, and crospovidone. Among these, crospovidone demonstrated the fastest disintegration time (0.31 minutes) and was selected for the core formulation. The core tablets were subsequently press-coated with hydrophilic and hydrophobic polymers, primarily hydroxypropyl methylcellulose K4M, to achieve the desired lag time. The optimized formulation with a 360 mg polymer barrier provided complete and rapid drug release after a 6-hour delay, as confirmed by in vitro dissolution studies. Stability studies over six months showed no significant changes in the drug release profile. The findings suggest that press-coated tablet technology can be effectively utilized to develop chrono-modulated drug delivery systems for conditions like nocturnal asthma.

**MOSQUITO REPELLENT NANOCOSMETIC CREAM USING ORANGE PEEL EXTRACT**

Abhinandh K S and Rosemol K Jhon
Department of Pharmaceutics, Nirmala college of health sceince, Chalakudy, Thrissur, India - 680311.
abhinandhanitha@gmail.com

Mosquito-borne illnesses are still a concern to world health, particularly in tropical and subtropical areas. An efficient defense against mosquito bites and the spread of these diseases is the use of mosquito repellents. Chemical-based mosquito repellents can be harmful to human health, especially to children and pregnant women. The use of natural plant-based component is a potential approach in the development of sustainable and eco-friendly mosquito repellents, which is gained popularity in recent years. In this study, we prepared a mosquito repellent cream using orange peels, as orange peels are a rich source of essential oils including limonene, which has been found to have mosquito-repelling qualities. This research article describe how orange peels can be used to make mosquito-repelling cream which is used to ward off mosquito. The dried orange peels were cut into pieces with

ISBN: 978-81-980623-8-3

same ratio for fine particles used for extraction of oil. For the preparation of Nano cosmetic cream first we have to prepare the silver nanoparticle solution and then we incorporate the solution into cream base. It has been demonstrated that the resulting cream has substantial anti-mosquito capabilities and can offer protection. There are many benefits to using orange peels as a raw material for mosquito repellent cream, including its availability, affordability, environmental friendliness and also have antioxidant activity. Overall, our study demonstrates the potential of orange peels as a natural source of mosquito repellent and provides a simple and effective method for preparing a mosquito repellent cream.

The present work on the preparation of topical ethosomal gel containing fluconazole and clove oil was an attempt to utilize the immense potential of ethosomes as a carrier to increase the permeability. Fluconazole is a synthetic antifungal agent belonging to the first generation triazole group and clove oil from the family Myrtacea is the aromatic flower bed of a tree, Syzygium aromaticum that exhibits broad antifungal and antibacterial activity. Topically applied ethosomes can increase residence time of drug in stratum corneum and epidermis. It improves the horny layer properties both by reducing trans epidermal water loss and by increasing smoothness via replenishing lost skin lipids & improves patient compliance. The ethosomal formulation was prepared using hot method using varying concentration of soya-lecithin i.e.; 5 formulations were prepared. Formulations were evaluated for percentage drug release and other parameters for selecting the best formulation. The best optimized formulation was selected based on vesicle size, entrapment efficiency, spreadability and in-vitro drug release. Five runs were done from which most appropriate were selected by range of vesicle size (1.94µm), entrapment efficiency (94.3%), spreadability (14.53gm/sec). Further evaluation studies were done for the optimized formulation such as viscosity, pH, SEM, zeta potential, ex-vivo drug permeation, skin irritation study and anti-fungal study. Therefore, the ethosomes containing soya lecithin (4%) having high amount of drug retained in skin, which can help in delivery of drug especially in fungal mediated skin diseases, thereby efficacy for prolonged period can be achieved with better patient compliance.

**Keywords:** Ethosomes, Fluconazole, Clove oil, Candida infections

**GREEN-SYNTHESIZED $CuFe_2O_4$ NANOPARTICLES: A MULTIFUNCTIONAL PLATFORM FOR CATALYSIS, REMEDIATION, AND DRUG DELIVERY**

Prabhat Dessai and Saiesh Bhosle
Parul College of Pharmacy, Parul University, P.O. Quetol, Quepem, Goa, India-403705.
desaiprabhat@yahoo.com

Nanotechnology, the manipulation of matter at the nanoscale, has revolutionized scientific advancement across multiple industries, including medicine, environmental science, and catalysis. This study presents a green and sustainable approach for synthesizing copper ferrite ($CuFe_2O_4$) magnetic nanoparticles (NPs) using Psidium guajava (guava) leaf extract as a biogenic reducing and stabilizing agent. The synthesized NPs were characterized through IR, SEM, XRD, and UV-Vis spectroscopy, confirming their crystalline structure, nanoscale morphology, and magnetic properties. The $CuFe_2O_4$ NPs demonstrated excellent catalytic activity as heterogeneous catalysts in key organic transformations, such as the Biginelli reaction and the reduction of p-nitrophenol, showcasing their reusability and efficiency. Photocatalytic studies revealed their ability to degrade environmental pollutants, indicating strong potential in water purification applications. Furthermore, the nanoparticles exhibited notable antimicrobial and anti-inflammatory activities against a range of microorganisms, supporting their application in biomedical fields. Drug release studies using ibuprofen demonstrated their suitability for controlled drug delivery systems. The dual catalytic and biomedical functionality, along with an environmentally benign synthesis process, highlights the versatility of $CuFe_2O_4$ NPs. This work not only contributes to advancing green nanotechnology but also establishes a promising platform for applications in sustainable catalysis, environmental remediation, and pharmaceutical development. Future exploration in targeted drug delivery and magnetic hyperthermia could further enhance their impact in healthcare and nanomedicine.

anushaaddanki4@gmail.com

In the current study, nanosponges are prepared using a recently developed colloidal system that can be modified to work with both hydrophilic and hydrophobic drugs, thus overcoming issues with medication toxicity, decreased bioavailability, and drug release over a wide area. In the study, terbinafine was selected as a model drug for the treatment of onychomycosis. Accordingly, the current work aims to develop Terbinafine-loaded nanosponges using factorial design. To study the effect of independent variables such as total amount of polymer (Eudragit RS 100 in mg) and stabilizer (Polyvinyl Alcohol in %), a two-factor three-level factorial design was used using Stat-Ease Design Expert v12. The experimental design led to the preparation of nine formulations. Polymer (X1) and stabilizer (X2) were selected as independent variables. The dependent variables were particle size (nm) at a range of (100 to 250), Zeta potential (mV) at a range of (-30 to -40), and drug loading (%) at a range of (60-75%). Further optimized formulation was fabricated into nanogels using carbomer as a gelling agent at a concentration of (0.1%-0.5%) and varying concentrations of triethanolamine at 0.05%. Gels were evaluated for pH, viscosity, drug content, in vitro diffusion studies, in vivo studies, and cell line studies. An optimized gel formulation was subjected to stability and release kinetics.

**DESIGN, DEVELOPMENT AND CHARACTERIZATION OF EDOXABAN LOADED SOLID LIPID NANOPARTICLES**

Mahesh A and K. Balamurugan
Department of Pharmacy, ANNAMALAI UNIVERSITY, Annamalai Nagar, Chidambaram, Tamil Nadu, INDIA - 608 002
mahefast@gmail.com

Edoxaban is BCS class IV drug with poor aqueous solubility and intestinal permeability that results in poor oral bioavailability. Solid lipid nanoparticles (SLNs) are lipid based nanocarriers that enhance the solubility of hydrophobic drug substances and also improve their intestinal permeability similar to lipid digestion and absorption in the body. Current study aimed to prepare SLNs using Box-Behnken Design (BBD) and the resulting formulation was characterized for particle size, Poly Dispersity Index (PDI), and zeta potential. The formulation development was initiated by pre-formulation studies to confirm the authenticity of the drug substance and absence of drug excipient interactions. SLN formulations were optimized using BBD with three factors at three levels and five center points, resulting in 17 experimental runs obtained using DoE software. Glyceryl monostearate was used as lipid, lecithin as emulsifier and TPGS as co-emulsifier in the lipid phase. Aqueous phase is of 1.5% polysorbate 80 solution. Hot homogenization method was used to produce SLNs. The optimized formulation with 5% drug loading showed particle size of 120 nm, 0.213 PDI, and -24mV zeta potential. The entrapment efficiency was found to be 70%. Pre-formulation studies indicated that, there were no interactions between drug and excipients selected. Further in- vitro and in-vivo characterization is required to prove the full potential of SLNs for delivering the drug.

**DEVELOPMENT, OPTIMIZATION AND EVALUATION OF CO-CRYSTALS OF BCS CLASS IV DRUG**

Anshita Kawale , Dr. Tirupati Rasala, Nishita Nagpure, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

Hydrochlorothiazide cocrystals were formulated to improve its solubility and permeability. Hydrochlorothiazide is a diuretic belonging to BCS class IV category having low solubility and low permeability. In this research work, preformulation studies of the drug were carried which included wavelength selection, calibration curve, saturation solubility, micromeritic properties and FTIR and DSC. Cocrystals were prepared by using solvent grinding method. In preparation of cocrystals, various coformers were used with hydrochlorothiazide in various ratios The evaluation of cocrystals were done for 1:3 ratio with benzoic acid, tartaric acid and salicylic acid as conformer. Evaluation of cocrystal was done with respect to percentage yield, saturation solubility, micromeritic properties, permeability studies, drug content, In vitro dissolution, stability studies. Solid State Characterization done by FTIR, DSC, SEM, and PX-RD. Result of evaluation obtained maximum % Yield for TA3 batch. High saturation solubility was shown by BA3, TA3 and SA3 formulation. Maximum drug Content obtained by TA3 and SA3 formulation. The higher drug release hydrochlorothiazide of cocrystals as compared to pure drug due to increase solubility of hydrochlorothiazide due to crystal modification by cocrystallization. Tartaric acid formulation was selected as optimized formulation it show all the parameter higher than benzoic acid and salicylic formulation. Hydrochlorothiazide cocrystals with tartaric acid were stable for a period of 30 days with no significant change in the measured parameter. Thus hydrochlorothiazide cocrystal with tartaric acid were stable.

**API-IONIC LIQUID FORMULATION AS A NOVEL APPROACH TO ENHANCE CARBAMAZEPINE SOLUBILITY**

Manisha D. Chate and Swaroop R. Lahoti
Y.B Chavan College of Pharmacy, Dr. Rafiq Zakaria Campus, Chhatrapati Sambhaji Nagar (Aurangabad), Maharashtra, India- 431003.
manishachate20@gmail.com

In the current research, carbamazepine ionic liquid (CAR-IL) was synthesized by using citric acid. Carbamazepine has disadvantages, such as poor solubility and low bioavailability. To overcome these issues, an API-based ionic liquid was synthesized. The hydrogen bond is present between the OH group of citric acid and the amide group of carbamazepine, which is a cationic species, combining with the anionic species of citric acid. The CAR-IL was prepared using the solvent evaporation method. A 1:1 molar ratio mixture of carbamazepine and citric acid was dissolved in 5ml of methanol. This solution was then allowed to evaporate for two days to yield the desired product. The resulting (CAR-IL) Ionic liquid was obtained as an off-white solid powder. The CAR-IL obtained was confirmed through comprehensive analytical tests, including differential scanning calorimetry (DSC), X-ray diffraction (XRD), fourier transform infrared (FTIR) spectroscopy, and thermo gravimetric analysis (TGA). Furthermore, saturation solubility in water showed that the synthesized CAR-IL exhibited 4.55-fold improved solubility compared to pure carbamazepine. The UV spectra revealed no interference between the components, indicating that no significant interaction occurred. The in vitro studies (dissolution) of CAR-IL show 88.5% drug release. Preparation of CAR-IL is beneficial because it offers a multifunctional, eco-friendly, and effective strategy to enhance the solubility, dissolution, and delivery of carbamazepine widely used epileptic drug.

**Keywords:** Ionic liquid, carbamazepine, citric acid, solubility.

**PC-348**

**FORMULATION AND OPTIMIZATION OF A PRONIOSOMAL GEL OF TIZANIDINE HYDROCHLORIDE FOR SUSTAINED TRANSDERMAL DELIVERY**

Jasvitha Mandava and Saritha Medapati
Department of Pharmaceutical sciences, Vignan Institute of Pharmaceutical Technology(A), Duvvada, Visakhapatnam, Andhra Pradesh, India – 530049
jasvithamandava.jm@gmail.com

Tizanidine Hydrochloride (TZN), a BCS Class II drug with limited aqueous solubility and low oral bioavailability, This was formulated into a proniosomal gel to enhance solubility and enable sustained transdermal delivery. Proniosomes were composed of lecithin, cholesterol, and non-ionic surfactants, they transform into niosomes upon hydration. TZN-loaded proniosomes were prepared using the coacervation phase separation method with various surfactants (Tween 20, 40, 60, 80, and Span 80). The formulations were evaluated for vesicle size, polydispersity index (PDI), zeta potential, entrapment efficiency and morphology using optical microscopy, SEM and DLS analysis. The optimized formulation (F8) demonstrated a vesicle size of 169.7 nm, a PDI of 0.352, and a high entrapment efficiency of 93%, indicating uniformity and stability. The drug content and release were quantified via UV-Visible spectrophotometry at 318 nm and the In vitro release studies, were conducted using the dialysis bag diffusion method in phosphate buffer (pH 6.8), revealed sustained drug release beyond 24 hours. These findings suggest that proniosomal gel is a promising drug delivery system for enhancing solubility, stability and sustained transdermal release of Tizanidine Hydrochloride there by potentially improving therapeutic efficacy and patient adherence.

**Keywords:** Tizanidine Hydrochloride, Proniosomal gel, Transdermal drug delivery, Sustained release, UV-Visible spectrophotometry.

**NATURE MEETS NANOTECH: DUAL ROLE OF CLERODENDRUM SERRATUM-BASED SILVER NANOPARTICLES IN INFECTION CONTROL AND WOUND HEALING**

Meenakshi Singh and Ritu Raj Patel
Department of Medicinal Chemistry, Faculty of Ayurveda, Institute of Medical Sciences, Banaras Hindu University, Varanasi, 221005, India
meenakshisingh@bhu.ac.in

The rise of multidrug-resistant (MDR) ESKAPE pathogens and biofilm-associated infections poses a major therapeutic challenge, necessitating innovative strategies for effective infection control and wound management. This study reports the green synthesis of silver nanoparticles (AgNPs) and polyethylene glycol-coated AgNPs (PEG-AgNPs) using Clerodendrum serratum leaf extract and evaluates their dual antibacterial and wound-healing potential. Nanoparticles were synthesized, characterized and assessed for antibacterial, antibiofilm, and therapeutic activity. PEG-AgNPs demonstrated superior antibacterial efficacy with respect to MIC values 0.3906-12.5 µg/mL compared to AgNPs. Flow cytometry confirmed bacterial membrane disruption, and biofilm assays revealed potent inhibition against Pseudomonas aeruginosa and Acinetobacter baumannii. LC-MS analysis identified bioactive flavonoids, including pectolinarigenin, and salvigenin, which demonstrated strong binding affinities of -8.7 kcal/mol with key biofilm-associated proteins (ClpP1, PslG, BfmR, and OmpA) in molecular docking studies, elucidating their mechanistic role in biofilm disruption. To facilitate topical delivery, we aimed to design and develop a suitable Nanoformulation through a series of optimizations, the 3% PEG-AgNP gel emerged as the most effective formulation for further application. It exhibited uniform nanoparticle dispersion confirmed by SEM, with accelerated wound closure and promoted nearly complete healing in a rat excision model. This dual-action approach highlights the potential of C. serratum-derived PEG-AgNPs as a sustainable and effective nanoplatform for tackling two critical clinical challenges, infection control and wound repair. Through merging traditional medicinal knowledge with modern nanotechnology, this study not only provides mechanistic insight but also proposes a translationally relevant strategy that could complement or surpass existing antimicrobial and wound-care therapies.

**Keywords:** Clerodendrum serratum, PEG-AgNPs, Molecular docking, MDR-ESKAPE pathogens, wound healing.

**PC-350**

**DEVELOPMENT AND EVALUATION OF A RICE BRAN WAX-BASED EMULGEL CONTAINING GENTAMICIN FOR TOPICAL TREATMENT OF SKIN AILMENTS**

ISBN: 978-81-980623-8-3

Grishma Kamble, Dr. Tirupati Rasala , Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

The present study focuses on the formulation and evaluation of an emulgel system combining the therapeutic benefits of gels and emulsions for the treatment of skin ailments. Utilizing natural rice bran wax as a base and Gentamicin as the active pharmaceutical ingredient, three emulgel formulations (F1, F2, F3) were developed and tested. Rice bran wax was extracted, purified, and saponified, and its physicochemical properties were assessed before incorporation. The emulsions were prepared using surfactant blends and integrated into a gel matrix containing Carbopol 940. Among the formulations, F1, which incorporated 2% Carbopol, exhibited the most desirable characteristics, including optimal spreadability, bioadhesion, pH, and viscosity. In vitro drug release studies using a Franz diffusion cell showed that F1 had the most rapid and complete drug release over a 120-minute period. Antimicrobial testing confirmed the activity of all formulations, with F1 showing the highest zone of inhibition, though slightly less potent than standard Gentamicin treatments. The findings demonstrate the successful use of rice bran wax in a stable and effective topical emulgel formulation, offering enhanced patient compliance due to its ease of application and promising therapeutic potential. Further in vivo studies are recommended to evaluate clinical effectiveness and optimize the formulation's antimicrobial profile. This research supports the use of sustainable, natural materials in topical drug delivery systems without compromising pharmaceutical standards.

**Keywords:** Emulgel, Rice Bran Wax, Gentamicin, Topical Drug Delivery, Skin Ailments, Carbopol 940.

## FORMULATION, DEVELOPMENT AND EVALUATION OF A VANISHING CREAM INCORPORATING ETHANOLIC TAPROOT EXTRACT OF *DAUCUS CAROTA*

Vikrant P. Taware, Shruti D. Nimbalkar and Gayatri B. Shinde
Department of Pharmaceutics, SVPM, College of Pharmacy, Malegaon (BK), Baramati, Pune, Maharashtra, India - 413115
taware.vikrant@gmail.com

This study investigates the formulation and evaluation of a vanishing cream incorporating ethanolic taproot extract of *Daucus carota* (carrot), aiming to provide rapid absorption, a non-greasy texture, and prolonged hydration. Vanishing creams, characterized as oil-in-water (O/W) emulsions, are renowned for their quick absorption and smooth, matte finish. The primary objective was to assess the impact of various ingredients and formulations on the cream's ability to deliver moisturization, smoothness, and a matte finish. Four formulations (F1–F4) were developed using a combination of emulsifiers, humectants, oils, preservative and aqueous phase. The ethanolic extract was prepared by macerating fresh taproots with food-grade ethanol at a 1:5 (w/v) ratio for 7–14 days at room temperature, followed by filtration and evaporation under reduced pressure. This extract was then incorporated into the vanishing cream. The final product was evaluated for appearance, odor, pH, spreadability, homogeneity, viscosity, consistency, and irritancy. Results indicated that all formulations exhibited even spreadability, rapid absorption, and maintained skin hydration over time. Formulation F1, in particular, demonstrated a creamy white color, smooth texture, pleasant carrot scent, pH of 5.7, spreadability of 12.3 g.cm/sec, uniform homogeneity, viscosity of 1500 cP, medium consistency, and non-irritant properties. Thus, it can be concluded F1 provided a matte finish, enhanced skin smoothness, and long-lasting hydration, exhibiting the most desirable attributes. Further studies are recommended to optimize texture, absorption rate, and skin-feel characteristics.

**Keywords:** Vanishing cream, Daucus carota extract, oil-in-water emulsion, skin hydration.

## DEVELOPMENT OF MICROCRYSTALLINE CELLULOSE POWDER FROM COTTON LINTERS USING A BIOCHEMICAL PROCESS FOR TABLET EXCIPIENTS

Sufiya Khan, Ms. Harshali Shende, Mr. Shubham Kamble, Dr. Tirupati Rasala
THE ROYAL GONDWANA COLLEGE OF PHARMACY, NAGPUR

Microcrystalline cellulose (MCC) is a widely utilized excipient in pharmaceutical tablet formulations due to its excellent compressibility and binding properties. Traditionally sourced from costly wood pulp or refined cotton, alternative sustainable sources such as cotton linters are being explored. This study presents a novel biochemical process for the production of MCC from cotton linters using crude enzymes derived from Aspergillus sp. VM-1, cultivated on banana pseudostem waste. The cotton linters, containing 90–98% cellulose, underwent enzymatic hydrolysis at a 1:20 material-to-liquor ratio, followed by bleaching with hydrogen peroxide and sodium hydroxide at 90–95°C. This method significantly reduces alkali consumption and energy input compared to conventional techniques. The resulting MCC exhibited an α-cellulose content of 98.05% and a degree of polymerization of 210, comparable to commercial Avicel® PH101. Physicochemical characterization confirmed that the cotton linter-based MCC met pharmacopeial standards. When evaluated as a direct compression excipient in paracetamol tablets, the enzymatically derived MCC demonstrated excellent flow, compressibility, and mechanical strength, albeit with a slightly longer disintegration time (9.21 minutes) compared to Avicel® PH101 (4.50 minutes). However, both formulations exhibited similarly high dissolution rates, confirming the potential utility of cotton linter-derived MCC in solid dosage forms. This study establishes an eco-friendly, cost-effective, and sustainable enzymatic pathway for MCC production from agro-industrial residues. The process not only valorizes cotton linters but also supports green chemistry initiatives in pharmaceutical manufacturing by minimizing chemical usage and environmental burden.

**PC-353**

## FORMULATION AND CHARACTERIZATION OF SODIUM ALGINATE-BASED FLOATING MICROBEADS FOR VALACYCLOVIR HYDROCHLORIDE

Anwesha Halder, Sudipta Das, Sankar Narayan Bhunia, Sawan Das, Dip Bhattacharjee, Soumik Hazra
Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, West Bengal, India – 741222.
anweshahalder660@gmail.com

The present work successfully achieved the formulation and evaluation of floating microbeads designed for the gastroretentive delivery of valacyclovir hydrochloride. This formulation aims to enhance the bioavailability of the antiviral drug and provide sustained release. In this study, six formulations (F1–F6) were developed using the ionotropic gelation technique, incorporating sodium alginate in combination with HPMC or Carbopol 934P. Floating microbeads were prepared using these polymer mixtures and evaluated for surface morphology, particle size, percentage yield (up to 52.61%), swelling index (up to 145%), in vitro drug release (up to 57.72% over 4 hours), and drug entrapment efficiency (up to 90.47%). The particle size ranged from 5 to 8.5 mm. Floating behavior was confirmed through in vitro buoyancy studies, where formulation F1 showed the best floating ability, 31% of the beads remained buoyant for 24 hours in simulated gastric fluid (0.1 N HCl). The results, particularly the drug release kinetics, demonstrated sustained drug release behavior and indicated the potential for achieving consistent therapeutic plasma levels, reducing dosing frequency, enhancing drug absorption, and improving the drug release profile within the gastrointestinal tract. This simple formulation strategy is advantageous for drugs like valacyclovir. It can be further optimized and scaled up for clinical applications in the treatment of viral infections such as herpes simplex and herpes zoster. This approach offers a more patient-friendly and effective alternative to conventional oral antiviral therapy, supporting improved therapeutic outcomes and better compliance in long-term antiviral treatment.

**Keywords:** Valacyclovir hydrochloride, microbeads, ionotropic gelation method, entrapment efficiency, HPMC.

**PC-354**

## FORMULATION DESIGN AND EVALUATION OF AN ANTIMICROBIAL HYDROGEL PATCH CONTAINING ALLIUM ASCALONICUM EXTRACT

1 Jasna Kunnathodika*, 2 Dr. Sibi P I, 2Febin Ashraf Parambadan,2Lanees Chundanveetil Kuttikadan Maliyekkal,2Shahana Pullat, 2Musharaf Nabi Khanday,2Dr. Sirajudheen M K
1 KMCT Institute of Pharmacy, Chellur, Pazhur P.O., Kuttippuram, Malappuram, Kerala
2Jamia Salafiya Pharmacy College, Pulikkal, Malappuram, Kerala

ISBN: 978-81-980623-8-3

Skin and tissue infections are extremely difficult to treat and are frequently made worse by antibiotic resistance and side effect from traditional therapies. The creation and assessment of anti-microbial hydrogel patch contain extract from Allium Ascalonicum is the main goal of this work. Antimicrobial qualities of the extract, such as its anti-fungal and anti-bacterial capabilities, are well documented. This work offers a novel method of using a hydrogel patch that is bioactive and contains extract from Allium Ascalonicum. The procedure entails locating shallots, isolating bioactive substances, and creating hydrogel patch with certain ingredients. The quality of the patch is evaluated by different matrices, and the integrity of the bioactive components is guaranteed by characterisation using Fourier- transform infrared spectroscopy. The potential of Allium Ascalonicum to fight infections and the creation of unique hydrogel patch for skin and tissue infections are highlighted in the study's conclusion, adding to the body of knowledge on natural solution to problems with conventional medicine.

**Keywords:** Allium Ascalonicum, Extract, Skin infections, Antimicrobial activity

**PC-355**

## DEVELOPMENT OF AZILSARTAN MEDOXOMIL CO-CRYSTALS USING BENZOIC AND MALEIC ACID: A STRATEGY TO IMPROVE BIOPHARMACEUTICAL PROPERTIES

Arya Kohad , Dr. Tirupati Rasala , Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

Azilsartan Medoxomil, classified under BCS Class IV, exhibits poor aqueous solubility and limited permeability, leading to low oral bioavailability. This study aimed to enhance its solubility and dissolution profile by formulating co-crystals using different co-formers. Benzoic acid and maleic acid were employed as co-formers through two techniques: solvent evaporation and solvent drop grinding. The prepared co-crystals were evaluated for solubility, crystallinity, dissolution behavior, and physicochemical properties. Results demonstrated significant improvement in aqueous solubility and drug release compared to the pure drug and the marketed formulation. Among the formulations, F2—Azilsartan Medoxomil co-crystallized with benzoic acid via the solvent drop grinding method—showed the most promising results. It exhibited the highest degree of crystallinity (85.59%) and maximum drug release (87.35% at 12 hours). FT-IR analysis confirmed intermolecular interactions between the drug and co-formers, while SEM revealed distinct morphological changes. The findings suggest that co-crystallization effectively modifies the physical properties of Azilsartan Medoxomil without altering its chemical structure. In conclusion, the co-crystal approach, especially using benzoic acid as a co-former, offers a promising strategy to enhance the solubility, dissolution rate, and potentially the bioavailability of poorly soluble drugs like Azilsartan Medoxomil. However, further in vivo and long-term stability studies are warranted to fully validate these outcomes.

**Keywords:** Azilsartan Medoxomil, co-crystals, solubility enhancement, bioavailability, benzoic acid, maleic acid, solvent drop grinding, solvent evaporation, crystallinity, drug release.

**PC-356**

## FORMULATION AND ANTIMICROBIAL EVALUATION OF TIN OXIDE NANOPARTICLES SYNTHESIZED VIA CO-PRECIPITATION AND OPTIMIZED SPRAY DRYING TECHNIQUES

Sanskruti Kaikade , Dr. Tirupati Rasala, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

Nanotechnology has revolutionized the biomedical field through the development of novel materials with enhanced properties. In this study, tin oxide ($SnO_2$) nanoparticles were synthesized using the co-precipitation method and optimized via spray drying and high-speed homogenization techniques to enhance their physicochemical and antimicrobial characteristics. The primary objective was to achieve nanosized particles with improved antibacterial efficacy suitable for therapeutic applications. Four trial formulations were evaluated, varying in precursors, pH adjustments, and drying methods. The optimized batch resulted in nanoparticles with a mean particle size of 243.2 nm and a 40% practical yield. Comprehensive characterization was performed using Fourier-transform infrared spectroscopy (FTIR), X-ray diffraction (XRD), field emission scanning electron microscopy (FESEM), and energy-dispersive X-ray spectroscopy (EDS), confirming the crystalline structure and elemental composition of $SnO_2$. Zeta potential analysis demonstrated good stability with a potential of -18.5 mV. Antimicrobial activity was assessed using a 100 ppm nanoparticle solution against Escherichia coli and Staphylococcus aureus, resulting in complete inhibition of bacterial growth over 24 hours without recurrence. The study concludes that $SnO_2$ nanoparticles possess potent antibacterial properties and demonstrate promising potential for applications in infection control and biomedical formulations. Their efficacy, combined with scalable synthesis methods, positions them as strong candidates in nanomedicine for combating microbial resistance.

**Keywords:** Tin oxide nanoparticles, co-precipitation method, antimicrobial activity, spray drying, zeta potential, biomedical applications.

**PC-357**

## TARGETED DELIVERY OF CR-42-024 USING ALBUMIN NANOPARTICLES: A NOVEL STRATEGY FOR ENHANCING ANTI-CANCER EFFICACY

Janvi Katole , Dr. Tirupati Rasala, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

The clinical application of CR-42-024, a potent tubulin polymerization inhibitor, is limited by its poor solubility, low tumor specificity, and non-selective toxicity. This study presents the design, synthesis, and evaluation of CR-42-024-loaded serum albumin nanoparticles (CR-SA NPs) as an innovative drug delivery system to overcome these barriers. Nanoparticles were fabricated using a modified desolvation technique, where ethanol was added as a desolvating agent and glutaraldehyde was employed as a crosslinker. The resulting CR-SA NPs demonstrated favorable physicochemical properties, including a spherical morphology, an average diameter of ~130 nm, and a zeta potential of approximately -30 mV, indicating good colloidal stability. Drug encapsulation was optimized to achieve a loading capacity of ~6 µg/mg albumin, with sustained release characteristics and no initial burst release. Cellular toxicity assays on the SW-620 colon cancer cell line revealed that CR-SA NPs had significantly lower IC50 values compared to free CR-42-024, highlighting their superior cytotoxic potential. These findings suggest improved intracellular delivery and therapeutic efficacy. While the current formulation utilizes glutaraldehyde, known for its potential toxicity, further studies are recommended to identify safer crosslinking agents for clinical translation. Overall, CR-SA NPs offer a promising platform for targeted cancer therapy, minimizing systemic toxicity while maximizing drug delivery to tumor sites. Future in vivo evaluations and formulation refinements are necessary to establish their potential in clinical oncology.

**Keywords:** Albumin nanoparticles, CR-42-024, tubulin polymerization inhibitor, targeted drug delivery, nanoparticle formulation, cancer therapy, controlled release, cytotoxicity, encapsulation efficiency, colorectal cancer, SW-620 cell line.

**PC-358**

## FORMULATION AND EVALUATION OF SILVER–QUERCETIN NANOCOMPLEX AND ITS EFFICACY AGAINST CERVICAL CANCER

Shrishti Kakde, Dr. Tirupati Rasala, Shubham Kamble

This study investigated the therapeutic potential of quercetin, a natural flavonoid found in various fruits and medicinal plants, in combination with silver nanoparticles (AgNPs) for pharmaceutical applications, with a focus on anticancer activity against cervical cancer. A metal–quercetin nanocomplex (MQNC) was formulated using silver via a green synthesis method. The resulting AgNPs demonstrated high drug entrapment efficiency and optimal particle size, indicating favorable physicochemical characteristics for drug delivery. The nanocomplex was comprehensively characterized using UV-Visible spectroscopy, Fourier Transform Infrared Spectroscopy (FT-IR), Scanning Electron Microscopy (SEM), Energy-Dispersive X-ray Analysis (EDX), X-ray Diffraction (XRD), zeta potential, and particle size analysis. UV-Vis spectra showed characteristic absorption shifts confirming nanoparticle formation, while FT-IR spectra revealed successful complexation of quercetin with silver ions. The in vitro cytotoxicity of the silver–quercetin nanocomplex was evaluated against HeLa cervical cancer cell lines using the MTT assay. The nanocomplex exhibited a significant cytotoxic effect, with an $IC_{50}$ value of 11.76 µg/mL, indicating enhanced anticancer potential compared to

ISBN: 978-81-980623-8-3

quercetin alone. These findings suggest that the silver–quercetin nanocomplex can serve as a promising candidate for targeted cervical cancer therapy. Further studies are recommended to explore the mechanism of action, optimize the formulation, and evaluate the in vivo efficacy and safety of this novel nanocomplex.

**Keywords**: Quercetin, silver nanoparticles, anticancer, cervical cancer, HeLa cell line, nanocomplex, Bottom of Form

**PC-359**

**DEVELOPMENT AND EVALUATION OF SUPERABSORBENT GELATIN-PVA FILMS FOR ENHANCED WOUND**

Mahi Sirsat, Dr. Tirupati Rasala, Shubham Kamble
The Royal Gondwana College of Pharmacy, Nagpur

The effective management of wound exudate is essential to accelerate healing and prevent infection in chronic and acute wounds. This study presents the development and evaluation of a novel wound dressing film formulated using gelatin and polyvinyl alcohol (PVA), crosslinked in-situ with glutaraldehyde, and plasticized with glycerin. The resulting superabsorbent film is designed to simultaneously absorb exudate and deliver antiseptic agents through a diffusion-based mechanism, making it suitable for incorporation into multilayered wound dressings. The formulation process involved dissolving PVA and gelatin in aqueous media under controlled temperatures, followed by blending, crosslinking, and film casting. The prepared films were subjected to extensive physicochemical and mechanical evaluations, including FTIR, thermal analysis (DSC and TGA), moisture vapor transmission rate, folding endurance, gel content, and antimicrobial testing. Results confirmed the film's structural stability, high water absorption capacity (35 g/g), and integrity loss upon hydration—essential for releasing therapeutic agents. FTIR spectra indicated successful crosslinking of gelatin without disrupting the PVA backbone. Thermal stability was maintained up to 150 °C, and antimicrobial testing showed promising activity, supporting its role in infection control. The developed film demonstrated favorable characteristics such as translucency, flexibility, uniform thickness, and soft texture, making it a viable option for use in exudate-heavy wound environments. These findings suggest that the optimized gelatin-PVA film holds potential as an advanced wound dressing component, offering a synergistic approach to exudate management and localized antimicrobial delivery.

**Keywords:** Wound dressing, superabsorbent film, polyvinyl alcohol, gelatin, glutaraldehyde, in-situ crosslinking, exudate management, antimicrobial activity.

Antiemetic drugs used to control nausea and vomiting caused by cytotoxic chemotherapy have a short duration of action, typically up to 6 hours, requiring multiple daily doses. Frequent dosing is difficult for patients suffering from emesis, leading to poor compliance and reduced treatment effectiveness. To overcome this, a drug delivery system that provides long-acting release, increases gastric retention, and improves bioavailability is necessary. Ondansetron Hydrochloride is prescribed for nausea and vomiting has a narrow absorption window in the stomach and low solubility in intestinal pH, resulting in reduced bioavailability beyond the gastric region. To resolve these challenges, gastro-retentive floating microspheres were developed to improve their absorption with an extended-release period. Here, floating microspheres are made using Ethyl Cellulose and Hydroxypropyl Methylcellulose (25% HPMC and 75% EC) by the solvent evaporation method. The optimized batch with an HPMC: EC ratio of 1:3 showed floating ability for over 12 hours, with particle sizes ranging from 154 to 345 µm and 60.52% drug entrapment efficiency. FTIR and DSC confirmed no chemical interaction between the drug and polymers, ensuring formulation stability. In vitro drug release shows up to 12 hours. The prepared floating microspheres successfully increased gastric retention, maintained the drug within its absorption window, and reduced dosing frequency, thereby improving bioavailability and patient convenience**.**

**Keywords:** Floating microspheres, Gastro-retentive system, Sustained release, Ondansetron Hydrochloride, EC, HPMC.

**FORMULATION AND CHARACTERIZATION OF CIPROFLOXACIN-LOADED CHITOSAN-ALGINATE MICROPARTICLES WITH VARYING CROSS-LINKING CONCENTRATION**

Ananta Gorain, Rimi Dey, Ambika Ghosh, Indrani Dutta and Sudipta Das
Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Tatla, Roypara, Chakdaha, Nadia, West Bengal, India – 74122
anantagorain2000@gmail.com

This study focuses on the formulation of ciprofloxacin-loaded chitosan-alginate microparticles using the ionotropic gelation technique, with calcium chloride (5%, 7.5%, and 10%) as the cross-linking agent. The objective is to enhance drug stability and provide controlled release by evaluating the impact of cross-linker concentration on yield, particle size, surface morphology, entrapment efficiency, and in vitro release, ultimately aiming to improve therapeutic efficacy and reduce dosing frequency through optimized formulation parameters. Formulation F3 exhibited the highest yield (88.20%), whereas F1 and F2 showed lower yields of 52.50% and 50.00%, respectively. A concentration-dependent reduction in particle size was observed, with F1 having the largest particles (0.617 ± 0.044 µm) and F3 the smallest (0.447 ± 0.029 µm). Morphological analysis revealed that F1 had a rough, folded surface, F2 showed a smoother structure, and F3 exhibited a uniform and dense morphology. The drug entrapment efficiency was highest in F1 formulation (71.49%), and lowest in F3 formulation (54.12%). All formulations exhibited sustained drug release over 240 minutes, with F1 releasing 70.95% and F3 releasing 50.15%. Release kinetics indicated that F1 and F2 followed first-order kinetics ($R^2$ = 0.9945 and 0.9976), while F3 best fit the Korsmeyer–Peppas model ($R^2$ = 0.9962), suggesting a transition from diffusion-controlled to polymer relaxation-mediated release with increasing cross-linker concentration. These findings suggest that modulation of cross-linker levels in polymeric microparticles offers a promising strategy for controlled delivery of ciprofloxacin, enhancing its therapeutic efficacy in the treatment of bacterial infections.

**Keywords:** Ciprofloxacin, Calcium Chloride, Microparticles, Chitosan-alginate, Morphology.

**DEVELOPMENT AND CHARACTERIZATION OF PIPERACILLIN TAZOBACTAM-LOADED AQUASOMAL GEL FOR THE TREATMENT OF NOMA**

Shafura S1, Anasuya Patil2 and Mahanthesh H M3
1,2&3 Department of Pharmaceutics: KLE College of Pharmacy, II Block Rajajinagar, Bengaluru, KLE Academy Higher Education and Research, Belgavi-590 010, Karnataka, India.

Noma is a rapidly progressive and often fatal infection of the mouth and face, which predominantly affects children between the age of two and six years. It begins as an ulcer on the gums and rapidly spreads into the jawbone, cheek, and facial soft tissues. In 2023 noma was added to the World Health Organization's list of . The study sought to create and optimize piperacillin-tazobactam-loaded aquasomes for buccal delivery, with the goal of improving drug stability and antibacterial activity. Aquasomes were created with calcium phosphate as the core, trehalose as the coating, and piperacillin-tazobactam as the medication. Piperacillin-tazobactam-loaded aquasomal gel was formulated using 1% Carbopol 934. A central composite design was used to optimize formulation variables. An optimized piperacillin-tazobactam-loaded aquasomes had a particle size of 186 nm, zeta potential of -19.37 mV, and PDI of 0.3697, suggesting stability and uniformity. Entrapment efficiency was 68.18%, whereas in-vitro drug release was 61.39%. Piperacillin-tazobactam-loaded aquasomal gel was formulated using 1% Carbopol 934 and demonstrated good pH, spreadability, drug content, and viscosity for buccal drug delivery. In- vitro and ex- vivo tests showed that drug release was sustained and increased mucosal penetration.

**Keywords:** Aquasomal gel, Noma, Piperacillin Tazobactam and Buccal delivery.

**FORMULATION AND COMPARATIVE ANALYSIS OF CIPROFLOXACIN HCL MICROSPHERES PREPARED WITH DIFFERENT COMBINATIONS OF POLYMERS USING EMULSION GELATION TECHNIQUE**

Udita Biswas, Debatri Roy, Rajdip Pal, Sayak Ghosh, Sudipta Das
Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, West Bengal, India-741222
ubiswas2406@gmail.com

This study was based on preparation of Ciprofloxacin HCL microspheres by using emulsion gelation method with natural gum, polymers, cross linking agents like sodium alginate and calcium chloride. It facilitated controlled release in the drug delivery system. Overall, three formulations were prepared and evaluated for size analysis, percentage yield, swelling index, drug entrapment efficiency, In Vitro drug release, drug release kinetics study and stability testing. According to the observations maximum swelling index was observed for F1 (100 %) and F3 had shown enhanced entrapment about 88 % with the optimized polymer level. In Vitro drug release study revealed that F3 had greatest percentage of drug release of (89.479 %). In general, of the three batches, F3 showed the best combination of properties with the lowest particle size about 70 µm. F3 had shown controlled release drug delivery system with R2 value of 0.929. At the end of 1 month of storage for stability study the percentages of drug release were found to be almost unchanged where the value for F3 was 85.112 %. No visible colour, odour, or physical and chemical changes were observed, which reflects good stability of the formulations under the test conditions.

**Keywords:** Microspheres, Ciprofloxacin HCL, Drug release kinetics study, Emulsion gelation method and Controlled release drug delivery.

**PC-364**

**DEVELOPMENT AND EVALUATION OF DICLOFENAC SODIUM SUPPOSITORIES**

Setu Majumder, Baishali Ghosh, Sudipta Das, Asitava Sarkar, Sneha Paul
Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, Nadia, West Bengal

In current research Diclofenac sodium suppositories were formulated by using fusion moulding method using different suppository bases like cocoa butter, PEG 4000 and gelatin with glycerin. The rectal route was chosen to avoid gastrointestinal side effects and to enhance patient compliance, especially in individuals unable to take oral medications. The prepared suppositories were evaluated by size determination using vernier caliper, melting time determination, weight variation, disintegration time determination and in-vitro drug release study. Drug release kinetics were determined by Zero order, First Order, Higuchi model, Hixon Crowel model, Korsmeyer model. The results showed that the suppositories met the required standards for physical characteristics, drug content and release profiles. All formulations met acceptable limits for weight variation, uniformity, and physical appearance. Melting time of the suppositories were within 25 minutes. Among the three bases, the PEG 4000 based suppositories exhibited high percentage of drug release within the desired time frame. The glycerin-gelatin based suppositories showed a more sustained release than PEG 4000, while cocoa butter base suppositories had a slower release rate with a prolonged sustained release activity. A prolong release pattern of diclofenac sodium suppositories were noticed over 240 minutes (38.88%). The study concludes that cocoa butter suppositories offer a prolonged release profile suitable for sustained therapeutic action, while PEG-based suppositories are ideal for faster onset of action and the suppositories follow the Higuchi model.

**Keywords:** Diclofenac Sodium, Sustain release, Fusion moulding.

dsk.ceutics@gmail.com

In the current research, polymeric nanoparticles of anti-diabetic drug Imeglimin hydrochloride (ImH) were formulated and evaluated. The objective behind the research was to achieve sustained drug release and reduce the required dosage compared to conventional formulations for improved Type 2 diabetes management. Imeglimin hydrochloride is a novel oral antidiabetic agent with a dual mechanism of action targeting mitochondrial function and insulin sensitivity. Despite its efficacy, it exhibits limited permeability and requires high oral doses. Polymeric nanoparticles were prepared using the double emulsion solvent evaporation method with poly (D, L-lactic-co-glycolic acid) (PLGA) as the polymer and polyvinyl alcohol (PVA) as the stabilizer. Different drug-to-polymer ratios, percentage of stabilizer were evaluated to optimize particle size, zeta potential, drug entrapment efficiency, and release profile. FTIR and DSC analysis indicated no chemical interaction between drug Imeglimin hydrochloride and polymer. The fabricated ImH loaded nanoparticles were characterized for particle size, drug-loading and drug release profiles. The optimized formulation exhibited a mean particle size of 189 ± 4.7 nm, a zeta potential of –32.8 ± 2.6 mV, and encapsulation efficiency of 76.5 ± 3.2%. FTIR and DSC analysis indicated no chemical interaction between Imeglimin hydrochloride drug and polymer. ImH-loaded PLGA nanoparticles exhibited sustained drug release over 24 hours in vitro. ImH-loaded PLGA nanoparticles demonstrated favourable characteristics for oral delivery, including sustained release and high encapsulation. The findings of this study suggest that the developed Imeglimin hydrochloride loaded polymeric nanoparticles have the potential to achieve optimal therapeutic outcomes and improving patient compliance.

**FORMULATION AND EVALUATION OF BIOPOLYMER-BASED MICROBEADS CONTAINING VALACYCLOVIR HYDROCHLORIDE**

Aritra Dutta, Sawan Das, Sankar Narayan Bhunia, Soutik Nandi, Rishikesh Kumar Choudhary, Sudipta Das
Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, West Bengal, India – 741222.
aritramotog84@gmail.com

In the present research, biopolymers using sodium alginate with gellan gum or guar gum are used to prepare microbeads containing an antiviral drug (Valacyclovir Hydrochloride) based on a microbead formulation. The objective aims to determine how different polymer-to-drug ratios affect the effectiveness of drug entrapment and the behavior of drug release, and the kinetic properties of Valacyclovir Hydrochloride using various mathematical models. The particle size of microbeads ranges from 0.4-0.8mm; hence, with a small size, there is an increase in surface area and release profile. A smooth, uniform, and spherical surface has been determined by surface morphological study using Digital Microscope and Scanning Electron Microscope (SEM). Analysis based on the six formulations of Valacyclovir Hydrochloride in which Formulation 6 showed the most promising results with the highest swelling index (160%), drug entrapment efficiency (67.95%), and controlled in-vitro release; hence, it releases the drug over a prolonged period. F5 also gives a high entrapment efficiency but with low swelling index and release characteristics. The drug release mechanism shows diffusion-controlled release, as the kinetic modelling of the drug follows the Higuchi model. Moreover, the linearity in both first and zero order release graphs suggests the microbeads offer predictable and long- lasted therapeutic effects. Hence, Valacyclovir Hydrochloride-loaded biopolymer-based microbeads increase patient compliance and efficacy by reducing the dose frequency of an antiviral drug. The study can give a promising approach in the modern pharmaceutical field against viral infections.

**Key Words:** Biopolymer, Valacyclovir hydrochloride, guar gum, gellan gum, sodium alginate

**FORMULATION AND EVALUATION OF NORFLOXACIN-LOADED ALGINATE MICROSPHERE USING GUAR GUM AND GELLAN GUM WITH DIFFERENT CROSS-LINKING AGENTS**

Souktik Bhowmick, Anik Mondal, Aziza Parvin, Rimi Dey and Sudipta Das

ISBN: 978-81-980623-8-3

Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, West Bengal, India -741222.
souktik16@gmail.com

The study aimed to develop and characterize Norfloxacin-loaded alginate microspheres using two natural gums i.e. guar gum and gellan gum in combination with various cross-linking agents, namely calcium chloride ($CaCl_2$), aluminum chloride ($AlCl_3$), and a combination of both with ionotropic gelation method. It focused on evaluating how the choice of polymer and cross-linking strategy affected physicochemical property and drug release behavior of the microsphere. A series of formulations were prepared and evaluated for percentage yield, particle size, surface morphology, drug entrapment efficiency, and in-vitro release behavior. The formulation's yield was found to vary between 64.20% (F1) and 88.60% (F6), indicating that dual crosslinking improves matrix integrity. Dual crosslinking agents (F3 and F6), resulted in small and more uniform particle size, ranging b/w 0.417mm (F6) to 0.633mm (F1). Scanning Electron Microscopy (SEM) analysis showed that F6 had the most consistent and compact surface, F3 appeared coarse and fibrous, F2 and F4 showed porous and uneven surfaces. Maximum entrapment efficiency 68.16% is achieved by F6, while 30.90% was the lowest value achieved by F2. According to the drug release behavior, F2 released the drug more quickly 93.65% after 240 minutes, while F6 showed the slowest release rate 57.38% during the same period. The most advantageous characteristics showed by the gellan gum based microspheres cross-linked with both $AlCl_3$ and $CaCl_3$ (F6), which included the best yield, the smallest particle size, the compact surface shape, and more prolonged drug release. Overall, the study was helpful for future application.

**Keywords:** Gellan gum, Guar Gum, Microsphere, Ionotropic gelation

**PC-368**

**FORMULATION AND EVALUATION OF LIPOSOME CONTAINING 5-FLUOROURACIL**

Abhik Debnath, Barsha Das, Sudipta Das, Arnab Samanta
Department of Pharmaceutics, Netaji Subhas Chandra Bose Institute of Pharmacy, Chakdaha, West Bengal, India – 741222.
abhikdebnath365@gmail.com

In the framework of this research, liposome containing 5-Fluorouracil (a key anticancer drug) was formulated. Once formulated, the liposomes underwent a series of characterization tests like Fourier Transform Infrared (FTIR) Spectroscopy, dynamic light scattering (DLS) analysis, drug entrapment efficiency, in vitro drug release study, surface morphology examination. It was found that the particle size ranging from 110-300 nm suggesting a relatively uniform particle distribution, the entrapment efficiency shows that F1 formulation achieved the highest drug encapsulation at 83.54% and F8 had the lowest at just 15.48% out of all nine formulations (F1-F9). This results suggest that increase in lecithin concentration may reduce the drug entrapment efficiency. The FTIR analysis confirmed that there were no chemical interactions between 5-Fluorouracil and the liposomal components during the formulation process. The FE-SEM analysis revealed that the liposomes had a consistent shape and structure. F1 batch shows the highest drug release at 54.51% and followed Korsmeyer-Peppas release model, indicating a sustained release behavior. Overall, the findings of this study highlight the potential of liposomal drug delivery system, especially for cancer treatment. This innovative delivery system holds strong potential to meet existing medical need and move the pharmaceutical industry closer to more personalized and targeted treatment option.

**Keywords:** 5-Fluorouracil, FTIR spectroscopy, dynamic light scattering, lecithin, FE-SEM.

**FABRICATION AND EVALUATION OF RITONAVIR FDDS TABLETS FOR CONTROLLED RELEASE AND BIOAVAILABILITY**

Sunil Firangi and S.N. Hiremath
Department of Pharmaceutics, MAM College of Pharmacy, Kalalburagi, Karnataka, India -585102
sunil_eyz@rediffmail.com

Ritonavir, a widely prescribed antiviral for HIV/AIDS, is practically insoluble in water and presents challenges in formulation and development. This research focuses on developing Ritonavir floating tablets for controlled drug release and prolonged gastric retention, aiming to enhance bioavailability, reduce dosing frequency, improve therapeutic efficacy, and increase patient compliance. The tablets were prepared using the wet granulation method with PVP K30, magnesium stearate, talc, sodium bicarbonate, citric acid, xanthan gum, lactose, and varying ratios of HPMC K4M and K100M. Post-compression tests assessed hardness, weight variation, thickness, diameter, drug content, lag time, buoyancy time, and in vitro dissolution. All formulations showed good mechanical strength. Sodium bicarbonate and citric acid produced $CO_2$ in 0.1N HCl, enabling buoyancy. Xanthan gum aided in controlled release. The combination of citric acid and sodium bicarbonate provided optimal floating capability. Among the formulations, RF6 (with HPMC K100M) showed drug release following mixed-order kinetics and Higuchi's mechanism. Higuchi's equation and Peppa's plots confirmed non-Fickian diffusion and sustained release behavior. The study concludes that the formulated tablets successfully retain the drug in the stomach for extended periods, improving its solubility, bioavailability, and therapeutic outcomes.

**Keywords:** Ritonavir, HPMC, Xanthan gum floating drug delivery system.

**DESIGN, DEVEOPMENT AND EVALUATION OF TRASNFEROSOMAL BUCCAL PATCHES OF CARDIOVASCULAR AGENT**

Ashish Prakash Gorle
R. C. Patel Institute of Pharmaceutical Education and Research, Shirpur Kavayitri Bahinabai Chaudhari North Maharashtra University, Jalgaon

Cardiovascular disease (CVD) is the foremost cause of mortality worldwide and one of the world's most critical health issues. Cardiovascular Agents reduces the heart rate as well as systolic blood pressure, which reduces the oxygen demand of the heart and thus treats CVD. Oral administration of Cardiovascular Agents has the disadvantage of low bioavailability due to an extensive and highly variable hepatic first-pass metabolism. In addition, they possess short a half-life hence requires frequent dosing. Thus, it is important to give the drug other than by oral route. IV route has poor patient compliance due to needle pain and assistance required. Therefore, designed, develop and evaluate transferosomes of Cardiovascular Agents and incorporate it into Buccal patch for release of drug propranolol hydrochloride (P-HCl), Transferosomes were prepared by thin film hydration technique using soya lecithin, Lipoids S 100 and tween 80. Formulations were subjected to %EE, MPS, PDI, zeta potential, In-vitro drug release etc. Optimized transferosomes showed good characteristics such as 87.42 %EE, 212.8 nm MPS, and uniform, spherical shape. Transferosomes were further incorporated it into buccal patch using carbopol-940 and ethyl cellulose. In-vitro drug release of P-HCl loaded transferosomal buccal patch was found to be 89.47% upto 12 hours, which was greater than plain P-HCl loaded buccal patch. Stability studies were performed on optimized formulations and were found to be stable at all the three temperature conditions, specially at 27±2℃ temperature. Thus, buccal patch of P-HCl formulated achieved patient compliance due to its easy applicability.

**PC-371**

**FORMULATION AND EVALUATION OF HERBAL NANOEMULGEL FOR ASSESSMENT OF ANTIMICROBIAL ACTIVITY**

**DEVELOPMENT OF MOUTH DISSOLVING TABLET USING NATURAL SUPERDISINTEGRANTS**

Faiza shaikh & Rajat sayyed
MCESS Allana College of pharmacy

Mouth dissolving tablets (MDTs), also known as orally disintegrating tablets (ODTs), represent a promising drug delivery system aimed at improving patient compliance, especially among pediatric, geriatric, and dysphagic populations. The use of natural superdisintegrants in MDT formulation not only enhances disintegration and dissolution but also offers biocompatibility, sustainability, and cost-effectiveness. This study focuses on the formulation and evaluation of MDTs using natural superdisintegrants such as Plantago ovata (Isapghula husk), Lepidium sativum (garden cress seeds), and Mucilage of Hibiscus rosa-sinensis. A model drug with poor solubility and conventional compliance issues was selected for incorporation. The tablets were prepared using direct compression technique and evaluated for pre- and post-compression parameters including hardness, friability, disintegration time, wetting time, and in vitro drug release. Results indicated that formulations containing natural superdisintegrants exhibited rapid disintegration (under 30 seconds) and enhanced dissolution profiles compared to conventional synthetic disintegrants like sodium starch glycolate. Among the natural agents tested, Plantago ovata demonstrated superior performance in both disintegration and drug release, likely due to its high swelling index and mucilage content. The study underscores the potential of natural superdisintegrants in developing effective, eco-friendly MDTs. This approach aligns with the current trend of green pharmacy and offers a scalable solution for improving therapeutic efficacy and patient adherence.

shradhadwivedi9@gmail.com

Rheumatoid arthritis (RA) is a chronic inflammatory disorder that leads to deterioration of the synovial membrane in joints, resulting in significant deformity and destruction of the joints. Although rheumatoid arthritis cannot be eliminated, many treatments can alleviate symptoms and avert consequences. A singular nanocarrier capable of targeting several variables may function as a prospective therapy for rheumatoid arthritis treatment. Although the glucocorticoid dexamethasone sodium phosphate (DSP) is shown effective in treating RA, its application is limited by tissue accumulation and related adverse effects. Moreover, the DSP necessitates bi-daily treatment to maintain plasma concentrations, hence reducing patient compliance. The multifunctional nanocarrier has been designed to address these shortcomings. Zinc Oxide ions are utilized to formulate the multifunctional nanocarrier, which is decorated with folic acid for targeting. The nanoparticles are defined by their morphological analysis, thermal stability, and molecular interactions. The synthesized FA-DSP-ZnONPs have appropriate antibacterial, anti-inflammatory, and antioxidant properties. The in-vitro release profile indicates improved cell viability and conforms to the Korsmeyer-Peppas model of release kinetics. Furthermore, pharmacological assessment in the Adjuvant-induced Arthritis (AIA) model demonstrates a notable decrease in inflammatory cytokines, paw thickness, and arthritic score. It also signifies that, relative to the DSP, there is a substantial decrease in the concomitant unfavorable effects on renal impairment, body weight, blood glucose levels, and hematological anomalies. The FA-DSP-ZnONPs shows significant enhancement of pharmacokinetic profile with minimal distribution of drug towards vital organs that signifies no side effects as compared to DSP alone. The studies indicate that FA-DSP-ZnONPs could function as an efficacious treatment for RA.

**Keywords:** Rheumatoid arthritis, anti-inflammatory, antioxidant, MTT assay, Adjuvant-induced Arthritis.

anjanaadhyapak@klepharm.edu

Hirsutism is a common endocrine disorder in women, marked by excessive terminal hair growth in androgen-dependent regions, often linked to polycystic ovarian syndrome (PCOS). Although Flutamide, a nonsteroidal antiandrogen, is effective for treatment, its oral use causes hepatotoxicity and poor bioavailability. This study aimed to develop a topical Flutamide-loaded cubosomal gel using a Quality by Design (QbD) approach to enhance efficacy and safety. Flutamide-loaded cubosomes were prepared via a top-down method using glyceryl monooleate and Poloxamer 407 and optimized through a Central Composite Design (CCD) based on particle size and entrapment efficiency. The optimized cubosomes were incorporated into a xanthan gum-based gel. The formulation underwent extensive evaluation, including physicochemical characterization, in vitro release, ex- vivo permeation, analytical method development via HPLC, and in-vivo efficacy and irritation studies using female Wistar rats. The optimized cubosomes displayed a mean particle size of 122.7 nm, a zeta potential of –24.3 mV, and an entrapment efficiency of 78.67%. The cubosomal gel showed ideal pH (6.8), high viscosity (4290 cps), and excellent spreadability. Drug content analysis confirmed uniform distribution (98.5%). In vitro studies showed sustained drug release over 12 hours (83.2%), while ex-vivo skin permeation studies indicated enhanced transdermal delivery compared to plain gel. The in vivo, rats treated with cubosomal gel showed significantly reduced hair regrowth and no signs of erythema or edema. Histopathological analysis demonstrated decreased follicular density and normal skin architecture. The Flutamide-loaded cubosomal gel offers an effective and safe alternative to oral therapy for hirsutism, improving bioavailability and reducing systemic toxicity.

**A NOVEL APPROACH TO ENDOMETRIOSIS MANAGEMENT: DESIGN, DEVELOPMENT AND EVALUATION OF DUAL DRUG-LOADED DELIVERY SYSTEM**

Sharanya Paramshetti, Mohit Angolkar, Asha Spandana K M, Riyaz Ali M Osmani
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, S.S. Nagar, Mysuru, Karnataka, India-570015.
paramshettisharanya@gmail.com

Endometriosis (EM) is a chronic, inflammatory disorder defined by the abnormal growth of endometrial-like tissue outside the uterine cavity, leading to severe pelvic pain, dysmenorrhea, infertility, and reduced quality of life. Affecting approximately 10% of reproductive-age women globally, current diagnostic and therapeutic strategies remain limited, often relying on hormonal treatments that carry significant side effects and high recurrence rates. Given the multifactorial nature of EM, involving genetic, immune, hormonal, and environmental factors, there is an urgent need for innovative, non-hormonal therapies. In this context, the present study aims to develop lipid polymer hybrid nanoparticles (LPHNPs) loaded with two drugs as a novel, non-hormonal approach for targeted endometriosis therapy. This system combines anti-angiogenetic and antioxidant drugs, aiming to disrupt the dysregulated molecular and signalling pathways involved in EM

ISBN: 978-81-980623-8-3

pathogenesis. LPHNPs were formulated using the thin film hydration technique, with process parameters optimized using the Box-Behnken design (BBD), and characterized through various analytical techniques. SEM and TEM imaging confirmed the spherical shape of the particles, while the optimized nanoparticles exhibited an average particle size (PS) within the desired range and a high zeta potential, ensuring stability. The drug entrapment efficiency was found to be 84.56% and 87.65% for the two drugs, respectively. In vitro irritation studies using the HET-CAM method confirmed the non-irritant nature of the formulation, supporting its safety for clinical use. This nanoparticle-based strategy holds promise for improving therapeutic outcomes, minimizing adverse effects, and sustained drug release, addressing critical clinical gaps. In conclusion, this study highlights nanotechnology's promise as a transformative approach for endometriosis treatment, potentially revolutionizing care and offering renewed hope to millions of women globally.

mauli888@gmail.com

This study aimed to develop graphene oxide (GO) nanoparticles (NPs) loaded with quercetin (QUE) for targeted oncological applications, enhancing therapeutic efficacy while minimizing adverse effects. QUE-GO NPs were synthesized using Tween 80 and probe sonication. A Box-Behnken Design (BBD) optimized three critical parameters: GO weight, surfactant volume, and sonication time. The optimized formulation (Batch 14) exhibited an entrapment efficiency (EE) of 92.5 ± 0.7%, a particle size of 86.9 ± 0.46 nm, and a polydispersity index (PDI) of 0.158 ± 0.001, confirming stability. Sustained drug release (88.60 ± 2.3% over 8 h; n = 3) was observed. Cytotoxicity assays demonstrated significantly enhanced efficacy against MCF-7 breast cancer cells (IC50: 126.20 µg/mL; $p < 0.001$) compared to pure QUE (IC50: 175.89 µg/mL; $p < 0.05$; MW: 302.24 g/mol). HEK293 noncancerous cells showed minimal cytotoxicity (IC50: 1009.40 µg/mL), indicating a favorable safety profile. QUE-GO NPs are a promising nanocarrier system for targeted cancer therapy, offering enhanced cytotoxicity against tumor cells and reduced toxicity toward healthy cells.

The objective of the present study was to develop cyclodextrin-based nanosponge based topical gel of Bryophyllum pinnatum extract using crosslinker diphenylcarbonate and Carbopol polymer. The β-Cyclodextrin nanosponges were prepared using various concentrations of βCyclodextrin and diphenyl carbonate and characterized. Based on evaluation parameters the β-Cyclodextrin nanosponges formulations displayed narrow particle size, sufficiently high particle size, and maximum solubilization efficiency. Bryophyllum pinnatum extract was loaded into five β-Cyclodextrin nanosponge formulations by freeze-drying method and evaluated. Among all five formulation F5 formulation was selected. The particle size is 110.7 nm and zeta potential are -15.3 mV were displayed by F5 formulation hence formulated into a gel and evaluate. The optimized Bryophyllum pinnatum extract loaded nanosponge formulation (F5) was incorporated into a model carbopol gel formulation and was evaluated for stability and antimicrobial activity. The nanospongesloaded gel has a viscosity of 6831±0.34cps. The ph of the nanosponges-loaded gel is 6.2, and the spreadability is 12.61, showing that the gel loaded with nanosponges has excellent release and permeability. The results collectively suggest that because of the excellent release and good storage stability, cyclodextrin nanosponges based gel formulation of Bryophyllum pinnatum extract has tremendous potential to serve as a topical delivery system.

**Keywords:** β-Cyclodextrin, Bryophyllum pinnatum, diphenylcarbonate, nanosponge, freeze drying method

## ADVANCEMENTS IN STIMULI RESPONSIVE SMART HYDROGEL SYSTEMS FOR DIABETIC WOUND MANAGEMENT

Rajendra Kumar Jangde
University Institute of Pharmacy, Pt. Ravishankar Shukla University, Raipur, Chhattisgarh, 492010, India.
rjangdepy@gmail.com

Diabetic wounds (DWs) are a significant problem for people with diabetes mellitus because they are caused by a complicated pathophysiological microenvironment that makes people more likely to get sick and die. Conventional management approaches often fail to address the intricate characteristics of these wounds appropriately. Nanomaterials that respond to stimuli have become a potential way to heal wounds and grow new tissue because they can change to meet the needs of the wound environment. These innovative materials can react to various environmental stimuli, like temperature, light, pH, magnetic fields, and enzyme activity. This lets you very precisely control the release of therapeutic chemicals and helps tissues heal. To manage diabetic wounds, we need to use several different treatments that are specific to their pathophysiological traits, like frequent bacterial infections, long-term inflammation, high oxidative stress, and inadequate angiogenesis. The development of smart hydrogel/bandages that respond to stimuli opens up new ways to treat diabetic wounds. These smart hydrogels speed up the healing of diabetic wounds by reacting to numerous biological and physical cues. This lets researchers monitor the lesion and make precise modifications to the microenvironment around it. This paper provides a summary of the features of diabetic chronic wounds and describes the current clinical management approaches. We define the advanced applications of physical and biochemical signal-responsive materials/ hydrogel for the treatment of diabetic wounds through the modification of the wound microenvironment.

**Keywords:** Diabetic wounds, Stimuli-responsive delivery, current clinical treatment approaches.

## SKIN MICROBIOME AND ITS INFLUENCE ON COSMETIC PRODUCT DEVELOPMENT

Hanshakala Bista And Rajat Sayyed

The skin microbiome, a diverse ecosystem of microorganisms residing on the human skin, plays a crucial role in maintaining skin health and barrier function. Recent scientific advancements have highlighted the importance of this microbial community in influencing various dermatological conditions, including acne, eczema, and psoriasis. As a result, the cosmetic and pharmaceutical industries are increasingly shifting focus toward microbiome-friendly and microbiome-targeted skincare products. This paradigm shift has led to the emergence of novel formulations incorporating prebiotics, probiotics, and postbiotics aimed at restoring or enhancing the natural skin flora. Cosmetic product development now emphasizes preserving microbial balance, avoiding harsh ingredients that disrupt the microbiome, and fostering beneficial bacteria. Additionally, advanced sequencing technologies and metagenomics are being utilized to understand individual microbiome profiles, paving the way for personalized skincare solutions. Regulatory challenges, formulation stability, and consumer awareness remain key considerations in bringing these innovative products to market. This explores the growing relevance of the skin microbiome in cosmetic science and underscores its potential to revolutionize skincare by promoting health through microbial harmony. Future trends suggest that microbiome-based cosmetics will continue to evolve as an essential category in both preventive dermatology and cosmetic therapy.

**FORMULATION AND EVALUATION OF ORALLY DISINTEGRATING TABLETS (ODTS)**

Saniya Ilahi Shaikh, Swapnil Dounde

Orally Disintegrating Tablets (ODTs) are solid dosage forms that disintegrate or dissolve rapidly in the mouth without the need for water, offering improved patient compliance, especially for pediatric, geriatric, and mentally ill patients. The present study focuses on the formulation and evaluation of ODTs containing a model drug, aiming to enhance the bioavailability and convenience of administration. Superdisintegrants such as crospovidone, sodium starch glycolate, and croscarmellose sodium were incorporated in varying concentrations to optimize disintegration time and drug release. Direct compression method was employed due to its simplicity and cost-effectiveness. The prepared tablets were evaluated for pre-compression parameters like flow properties and post-compression parameters including hardness, friability, weight variation, disintegration time, and in-vitro drug release. Among the formulations, the batch containing 5% crospovidone showed the most desirable characteristics with a disintegration time of less than 20 seconds and over 90% drug release within 10 minutes. The study concludes that ODTs can be effectively developed using suitable excipients and techniques to improve patient acceptability and therapeutic efficacy.

**BIOTECHNOLOGY AND BIOTHERAPEUTICS: A NEW ERA IN PHARMACEUTICAL SCIENCE.**

SHAIKH ZAKIYA

Biotechnology and biotherapeutics are transforming the way we understand and treat diseases. Biotechnology uses living organisms, cells, or biological systems to create products that improve health and quality of life. In the pharmaceutical field, it helps develop new medicines, vaccines, and diagnostic tools. Biotherapeutics—also known as biologics—are medicines made from living cells, such as proteins, antibodies, or genes, that are used to treat serious conditions like cancer, diabetes, and autoimmune diseases. Unlike traditional chemical drugs, biologics are more targeted and often have fewer side effects. For B.Pharm students, learning about biotechnology and biotherapeutics is important, as these areas are becoming central to modern healthcare. They combine biology with technology to offer more effective and personalized treatments. As these fields continue to grow, they open up exciting opportunities for research, innovation, and careers in the pharmaceutical and healthcare industries.

**FORMULATION OF A FLOWER BASED NATURAL SUNSCREEN FOR ALL SEASON USE**

Sofia shaikh, Rajat Sayyed
Allan college of pharmacy, azam campus, Pune 411042
shaikhhhsofia@gmail.com

As a concern about the harm that synthetic sunscreen cause to the environment and the human health is increasing . That is why the attention is shifting to more plant-based alternatives. Flower extracts are one of the most promising natural uv flters because of the abundance of 294odelling294, anthocyanins , carotenoids and phenolic acide they contain . These physiologically active potent have skin – soothing, UV protection, antioxidant, anti-infammatory qualities. These fowers like hibiscus, calendula , chamomile, rose , blue pea , and lotus have many skin care benefts. The extract of this are typically made by water or hydroalcohol solutions.The research aims to formulate a natural sunscreen that is safe , weather adaptive, water resistant and is appropriate for rainy season using UV absorber derived from fowers . The sunscreen act as mild heating agent which provides comfort during winter . This startergies 294odelling the rising need for sustainable and natural sunscreens .

**Keywords**: Flower Extracts, natural sunscreen, UV absorbers, PA+++

**3D PRINTING IN PERSONALIZED DRUG FORMULATION: A PARADIGM SHIFT TOWARD PRECISION MEDICINE**

Shahid Ashpak Shaikh and Swapnil Dounde

The advancement of 3D printing (3DP) technology has opened new frontiers in pharmaceutical sciences, enabling the fabrication of complex, customized dosage forms with high precision. Personalized drug formulation using 3DP represents a transformative approach in medicine, allowing the production of patient-specific tablets tailored in terms of dose, release profile, geometry, and combination therapies. This study explores the application of 3D printing techniques—such as fused deposition 294odelling (FDM), inkjet printing, and stereolithography—in designing personalized oral drug delivery systems. The flexibility of 3DP allows for on-demand production of multi-drug polypills, pediatric-friendly shapes, and dosage forms with immediate or controlled release characteristics, all in a single unit. In the Indian context, where patient diversity and polypharmacy are prevalent, 3DP offers a scalable and adaptable solution for tailoring therapies based on age, weight, pharmacogenetics, or comorbidities. Additionally, 3DP minimizes drug wastage and supports decentralization of drug manufacturing, which is particularly advantageous in rural or resource-limited settings. Key challenges include regulatory uncertainties, scalability, material standardization, and integration into existing pharmaceutical supply chains. However, with ongoing research and supportive regulatory evolution, 3DP is poised to become a cornerstone of personalized medicine. This highlights the principles, advantages, and future potential of 3D printing in pharmaceutical formulation, emphasizing its role in driving precision, flexibility, and patient -centric healthcare.

**FORMULATION AND EVALUATION OF OSMOTIC TABLET OF CLOPIDOGREL**

Kusuma M.P and Archana M
RBVRR Women's College of Pharmacy,Barkatpura,Hyderabad
Affiliated to Osmania University
mpkusuma@gmail.com

Clopidogrel is growing as a drug of choice in the treatment and management of heart attack and cerebrovascular accident. It is stable and soluble in acidic pH, hence outlining an osmotic drug delivery system to regulate drug release with single dose is the goal of this study. This system also excludes the requirement for expensive and complicated laser drilling and sustain continuous therapeutic concentration. Total 15 formulations were prepared using Sodium chloride, Mannitol and Fructose are used as osmotic agents and cellulose acetate as a semi permeable membrane. The tablets were evaluated for precompression and post compression studies weight variation, diameter, hardness, friability, disintegration, and drug content and drug release in vitro. All the formulations showed good dissolution profiles. Among the all formulations F11 was optimized based on the state of release and it showed an extended drug release of 55.2% in 12hrs. The optimized formulation was stable for 3months and followed zero order kinetics.

**Keywords:** Osmotic tablet, Clopidogrel, Sodium chloride, Mannitol, Fructose.

ISBN: 978-81-980623-8-3

Luteolin (Lut), a naturally occurring flavonoid, exhibits notable medicinal properties, including anticancer and antioxidant activities. However, its poor water solubility, limited stability, and low bioavailability hinder its pharmaceutical applicability. In this study, luteolin was encapsulated into nanocapsules using a nanoprecipitation technique, with poly(ε-caprolactone), Tween 80, soybean oil, and varying amounts of phosphatidylcholine as key components. The resulting nanocapsules displayed nanometric size, narrow polydispersity index, negative zeta potential, high encapsulation efficiency, and excellent stability, including under thermal stress. Increased phosphatidylcholine content enhanced luteolin loading capacity. The nanocapsules with higher luteolin content demonstrated significant reactive oxygen species (ROS) scavenging activity and cytotoxic effects against human colon adenocarcinoma (HCT116) cells. These findings suggest that luteolin-loaded nanocapsules can effectively enhance the solubility, stability, and biological activity of luteolin, offering promising potential for future pharmaceutical applications.

**Keywords**: Luteolin Nano capsules, Phosphatidylcholine. Biocompatible polymer, Anticancer, Antioxidant

**PC-386**

## FORMULATION & EVALUATION OF (CHALCONE BASED- SEMI SYNTHETIC) NANO-GEL FOR THEIR, ENHANCED ANTI-INFLAMMATORY & ANALGESIC ACTIVITIES

PATHAN MUZAKKIR AHMED NISAR AHMED1, Dr. MD.RAYEES AHMAD2, Dr. SHAIKH GAZI3.
Dept. of Pharmaceutics, RP College of Pharmacy, Dharashiv, MH, 413501
& 3. Dept. of Pharmaceutical Chemistry, RP College of Pharmacy, Dharashiv, MH, 413501

Chalcones are a class of natural compounds that exhibit promising anti-inflammatory and analgesic properties, exemplified by compounds such as Curcuminoid chalcone and Naringenin chalcone. However, their therapeutic potential is often hindered by poor solubility and bioavailability. While various formulations are available, there is a pressing need to develop semi-synthetic Nano-formulations that can provide rapid effects with minimal side effects. The primary purpose of this work is to design and obtain a series of Chalcone-based semi-synthetic Nano-Gels, specifically the Chalcone–NSAID Herbal formulation. This formulation aims to target arthritis, gout, tendinitis, and inflammation—conditions that significantly affect many elderly individuals. By combining chalcones with herbal components, the formulation seeks to leverage the synergistic effects of both, enhancing therapeutic benefits. Chalcones are recognized for their anti-inflammatory and analgesic properties, while the addition of herbs can contribute additional therapeutic benefits, optimizing treatment outcomes. The development of a Nano formulation that uniquely combines chalcones with herbal components aims to enhance the treatment of inflammation and analgesia. By utilizing nanotechnology, this formulation seeks to improve the solubility and bioavailability of chalcones and herbal medicine, allowing for more effective therapeutic outcomes. This innovative approach offers a promising strategy for optimizing treatment while minimizing side effects.

**Keywords:** Chalcone, Nano-gel, Anti-inflammatory, Analgesic, Semi-synthetic.

## ENHANCEMENT OF SOLUBILITY OF POORLY WATER-SOLUBLE DRUG BY SOLID DISPERSION METHOD AND PREPARATION OF ORAL CAPSULE

TUKARAM M KALYANKAR

Rivaroxaban is an antiplatelet/anticoagulant drug used in treatment of venous thromboembolism, belongs to Biopharmaceutical Classification System Class II; hence has low solubility. The aim of this study was to enhance solubility of drug by solid dispersion method. Solid dispersion is combination of two component- hydrophilic matrix and hydrophobic drug. There are various methods used for preparation of solid dispersion from which solvent evaporation method was used in this research. The solubility of Rivaroxaban was increased by dissolving different polymers with Rivaroxaban API using suitable solvent (Dichloromethane+methanol) in three different ratios 1:0.5, 1:1, 1:1.5 and then this preparation kept for 24 hours in Hot air oven to get solvent evaporate. The best polymer and ratio screening was done with the help of solubility study, it was done with different buffers like pH 6.8 phosphate buffer, pH 4.5 acetate buffer, 0.1N HCL(pH 1.2), water with the help of UV spectrophotometer. The evaluation of final dosage form was done with the help of dissolution study in media 4.5 acetate buffer+0.2% SLS for about 2 hrs at specific time interval 10, 15, 30, 45, 60, 90, 120 minutes. Drug polymer compatibility study was done by different analysis like FTIR, XRD, DSC and SEM.

**Keywords:** Rivaroxaban, Solid Dispersion, Solvent Evaporation, anticoagulant, Polymers, BCS Class II, Solubility.

## FORMULATION AND OPTIMIZATION OF SOLID LIPID NANOPARTICLE FOR PALIPERIDONE BY CENTRAL COMPOSITE DESIGN

M. Venu, S. Manohar Babu and K. Balamurugan
Research Scholar, Department of Pharmacy, Annamalai University, Annamalai Nagar- 608 002.
venu.m.53@gmail.com

Paliperidone is indicated for the treatment of schizophrenia. It has an absolute oral bioavailability of about 28 % as it is poorly soluble in water and also undergoes hepatic first-pass metabolism. Initially, the solubility of paliperidone was improved by making complex with HP-ß-cyclodextrin (HP-ß-CD). The paliperidone and HP- ß-CD complex exhibiting highest solubility (1:3 molar ratio) was formulated as solid lipid nanoparticle (SLN) by considering three critical factors vis-à-vis concentration of solid lipid (glyceryl monostearate), probe sonication time and concentration of surfactant (labrasol). The SLN formulations were prepared as per central composite design (CCD) using high shear homogenization followed by the ultra-sonication technique. SLN formulations were evaluated for entrapment efficiency, particle size, polydispersity index, zeta potential and In-Vitro diffusion study. The optimized SLN formulation exhibited lowest particle size, PDI with stable zeta potential and drug release for 24 h. Hence the approach of formulating SLN for paliperidone after improving solubility by complexing with HP-ß-CD has the potential of improving In-vitro bioavailability.

**Keywords:** Probe sonication, GMS, Labrasol, Homogenization, Inclusion complexation.

## CEFTRIAXONE SODIUM-AGNPS LOADED HYDROGEL:AN OPTIMIZED NANO FORMULATION FOR ENHANCED WOUND RECOVERY

Lis Maria Joseph, Gururaj S Kulkarni, Mulla Ujma Riyaz, G Parthasarathy

ISBN: 978-81-980623-8-3

Injuries harbor a multifaceted and grave threat to the well-being and existence of individuals. Among the prevalent challenges is the, emergence of persistent wounds, which entail significant harm to the underlying tissues. Thus, the innovation of novel pharmaceutical materials offers a beacon of hope in enhancing treatment outcomes for infected wounds. In this investigation, we unveiled a synthesis approach of AgNPs- Ceftriaxone sodium loaded into hydrogel. The objective of the work was to demonstrate the therapeutic role of Ceftriaxone sodium-AgNPs loaded hydrogel for wound healing. Preparation of AgNPs, Preparation of CTX-AgNPs nanocomposite and Preparation of CTX-AgNPs loaded hydrogel for wound healing. Optimization carried by Box Bhenken Design of AgNPs, Incorporated CTX-AgNPs nanocomposite and CTX-AgNPs loaded hydrogel for wound healing characterization was found in standard limits and In Vivo study showed efficacy of wound healing extensive in optimized CTX-AgNPs loaded hydrogel.

**Keywords:** AgNPs, CTX-AgNPs nanocomposite, Hydrogel, In Vivo, Wound healing

**INNOVATIVE MICRONEEDLE BASED DRUG DELIVERY SYSTEM FOR TARGETED MANAGEMENT OF INFLAMMATION**

Bhagyashri Chigare, Aparna Bhalerao, Shivali Kanade, Janhavi Shahane and Rahul Rajale
School of Pharmaceutical Sciences, JSPM University, Pune, Maharashtra, India- 412207.
bvg.ccopr@gmail.com

Inflammatory skin conditions such as psoriasis, acne,eczema, ,and chronic wounds remain a significant concern due to the limitations of present therapies, including systemic side effects, poor dermal penetration and low patient adherence. Recently, microneedle (MN) technology has become a viable substitute for intradermal and transdermal drug delivery, providing better bioavailability, patient comfort, and minimally invasive administration. Tulsi and Manjishtha , two well-known Ayurvedic herbs with strong anti-inflammatory, antioxidant, and wound-healing qualities, are the subjects of the current study's design and development of anti-inflammatory microneedles. In order to guarantee batch-to-batch consistency, phytoconstituents were isolated and standardized using appropriate analytical techniques. Using micromolding techniques, biocompatible polymer-based microneedle arrays were created using PVA,PVPK polymers in a ratio of 1: 1 and 2:1 and tuned for features such as physical appearance, weight variation, percentage moisture content, penetration ability, drug loading capacity, mechanical strength, and SEM Analysis . The developed formulations were further evaluated for biocompatibility and in-vitro drug release . Protein denaturation assay were used to evaluate the anti-inflammatory effects, and ex-vivo testing revealed an improved skin localization in comparison to standard topical formulations. MNs loaded with tulsi and manjishtha were able to effectively penetrate the stratum corneum and release bioactives with a superior anti-inflammatory potential. The optimized formulation had a weight variation of 66.5 mg, moisture content of 5.55% and required 230 gm load to break it with the mechanical strength of 14.18 MPa. Hence according to the findings, this herbal MN system is a novel and patient-friendly way to treat skin inflammation.

**Keywords:** Microneedles, Tulsi, Manjishtha, Anti-inflammatory, Herbal formulation

**PLANT-MEDIATED GREEN SYNTHESIS OF SILVER NANOPARTICLES: METHODS, CHARACTERISATION, AND ANTIMICROBIAL APPLICATIONS**

Sathishkumar .D and Mrs.R.Rajakumari
Department of Biotechnology, PPG College of Pharmacy, Coimbatore, Tamil Nadu, India – 641035
sathishkumar701050@gmail.com

Nanotechnology, especially silver nanoparticles (AgNPs), is increasingly used in biomedical sciences for its potent antimicrobial properties. Traditional methods of nanoparticle synthesis often involve toxic chemicals, posing environmental and biological risks. The objective behind the research is to explore green synthesis of AgNPs using plant extracts as a safer, eco-friendly alternative, and to evaluate their antimicrobial activity and characterization profiles. AgNPs are synthesized by reducing silver nitrate using various medicinal plant extracts acting as natural reducing and capping agents. The process includes plant material preparation, extract boiling, silver ion reduction, and observation of color change. Nanoparticles were characterized using UV-Vis spectroscopy, FTIR, SEM, TEM, DLS, zeta potential, and XRD. Synthesized AgNPs showed predominantly spherical morphology with sizes ranging from 5–100 nm. They exhibited strong antibacterial activity against pathogens such as E. coli, S. aureus, and P. aeruginosa, by disrupting cell membranes, generating reactive oxygen species, and interfering with microbial DNA replication. Green synthesis of AgNPs using plant extracts presents a cost-effective, scalable, and non-toxic approach. Their promising antimicrobial potential supports further research into medical, pharmaceutical, and industrial applications.

**FORMULATION AND EVALUATION OF FLOATING TABLETS OF FUROSEMIDE**

Vaishali S Ghorpade, A. R. Pawar, R. B. Pandhare, V. K. Deshmukh
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist- Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
vaishnavighorpade2005@gmail.com

The present study aimed to develop and optimize gastro-retentive floating tablets of furosemide to enhance gastric residence time and sustain drug release for improved therapeutic efficacy. Preformulation studies confirmed compliance of the drug with pharmacopoeial standards in terms of organoleptic properties, melting point and spectral identity, while solubility profiling revealed strong pH dependence with maximum solubility in 0.1 N HCl. FTIR and DSC analysis confirmed compatibility between furosemide and selected excipients. Powder blend evaluation indicated good flowability and compressibility and compressed tablets met pharmacopoeial requirements for weight variation, hardness, friability, thickness and drug content uniformity. Optimization using a $3^2$ factorial design identified sodium bicarbonate concentration as the most significant factor influencing floating lag time, while both sodium bicarbonate and HPMC K15M significantly affected drug release at 12 hours. The optimized batch (F3) achieved a floating lag time of 64 seconds and 98.4% drug release at 12 hours, closely matching model predictions with minimal errors. In vitro dissolution confirmed sustained release over 12 hours, and accelerated stability studies over six months showed minimal changes in physical and functional attributes, indicating formulation robustness. The developed gastro-retentive floating tablet of furosemide demonstrates potential to enhance drug bioavailability and therapeutic performance by maintaining prolonged gastric residence and controlled drug release.

**Keywords:** Furosemide; Gastro-retentive drug delivery; Floating tablets; Sustained release; Stability studies

**FORMULATION AND EVALUATION OF PEEL-OFF MASK FROM BUTTERFLY PEA FLOWER**

Veer Sujata Umakant, Dube Tanuja Goraksha, Waghchaure Ravina Vilas
Saikrupa Institute of Pharmacy, Ghargaon, Shrigonda, Ahilyanagar, Maharashtra, India 413728.

It can be used to wash and moisturize the skin. Polymers, which can stick to skin in small layers, are used to make most peel-off masks. They are available as gel. Dead skin can be removed with peel-off masks. The most common skin disorders among young people, usually those between the ages of 18 and 25, are acne and oily skin. This study focuses on the development and testing of a topical peel-off gel mask that contains fenugreek, salt, carbopol, and polyvinyl alcohol (PVA) together with other chemical reagents including polymers. The gel formulation also contains preservatives and other ingredients including talc and triethanolamine. The efficacy of fenugreek powder in treating skin conditions, such as oily skin and reducing acne, has been documented in the literature. The formulations F1, F2, and F3 were made, and their color, aroma, consistency, washability, pH, spreadability and oil removing capacity and many characteristics that were assessed. Additionally, each batch's peel-off gel masks were made by drying them and measuring how long it took for them to peel. The peel-off gel formulation showed favorable outcomes across all evaluation metrics, indicating that the

ISBN: 978-81-980623-8-3

peel-off gel mask would be a good alternative to the artificial anti-acne gels.

Vinblastine (VB) is a well-known chemotherapeutic drug noted for its therapeutic efficacy; yet, its application is constrained by systemic toxicity. Targeted medication delivery via biocompatible zinc oxide nanoparticles (ZnONPs) is a promising approach to this challenge. This research aimed to evaluate the therapeutic efficacy of vinblastine-loaded zinc oxide nanoparticles (VB-ZnONPs) against colorectal cancer cells (Caco-2), examine their mechanism of action, and analyze their capacity to restrict metastasis. VB-ZnONPs were assessed for their cytotoxic effects on Caco-2 cancer cells by real-time cell analysis (RTCA) and morphological abnormalities. Following this, investigations into intracellular ROS production and cell migration were performed. VB-ZnONPs demonstrated concentration-dependent cytotoxicity towards Caco-2 cancer cell lines (IC50: 25.21 ± 2.44 µg/mL 24 h). The mechanism responsible for cell death was determined to be linked to elevated intracellular reactive oxygen species (ROS). Furthermore, VB-ZnONPs demonstrated the ability to impede cell migration in Caco-2 cancer cells. This study demonstrates the fascinating potential of VB-ZnONPs for targeted drug administration, providing increased efficacy with less side effects.

**Keywords:** Anticancer, Caco-2 Cancer Cells, Reactive oxygen species, Vinblastine sulphate, Zinc oxide nanoparticles.

**FORMULATION AND EVALUTION OF CURUMIN TRANSDERMAL PATCHES TO ENHANCE WOUND HEALING**

Sravani nalla and Ramani
Raghu college of Pharmacy, Dakamarri (v), Bheemunipatnam Mandal, Visakhapatnam, India – 531162
sravaninallana1@gmail.com

The study focuses on the formulation and evaluation of curcumin-loaded transdermal patches designed to enhance wound healing and overcome curcumin's poor oral bioavailability. Using the solvent casting method, patches were prepared with polymers like polyvinylpyrrolidone and methyl cellulose, along with plasticizers and penetration enhancers such as propylene glycol and dimethyl sulfoxide. The resulting patches underwent comprehensive physicochemical testing—including thickness, weight variation, folding endurance, surface pH, and drug content uniformity—as well as in vitro dissolution and ex vivo permeation studies. The optimized formulation exhibited strong mechanical properties, skin-compatible pH, and consistent drug distribution. Drug release followed first-order kinetics, and FTIR analysis confirmed no chemical interaction between curcumin and excipients. These findings support the potential of transdermal delivery systems to provide sustained release and improved therapeutic efficacy of curcumin for wound healing applications.

**Keywords:** Curcumin, Transdermal patches, Polyvinypyrrolidone, FTIR, Therapeutic efficacy.

**PC-397**

**DESIGN, FORMULATION AND EVALUATION OF SUBLINGUAL ORODISPERSIBLE TABLET FOR MIGRANE THERAPY BY USING NATURAL SUPERDISINTEGRANTS**

SHRUTI JAYKUMAR BIJWE

Migraine is a chronic neurological disorder characterized by recurrent headaches often accompanied by nausea, vomiting, and sensitivity to light or sound. The unpredictable nature of migraine attacks demands rapid therapeutic action for effective management. The present research was undertaken to formulate and evaluate sublingual orodispersible tablets (SODTs) of Eletriptan Hydrobromide, a selective serotonin (5-HT1B/1D) receptor agonist widely prescribed in the acute treatment of migraine. Despite its proven efficacy eletriptan suffers from poor oral bioavailability and extensive first-pass metabolism when administered through conventional routes thereby limiting its clinical potential. To overcome these challenges, sublingual delivery was explored as a promising alternative for faster onset of action and improved absorption. In this study, natural superdisintegrants such as fenugreek mucilage and isapgol mucilage were isolated, characterized and incorporated into the formulations to enhance disintegration and drug release. The tablets were prepared by direct compression and evaluated for precompression and postcompression parameters including hardness, friability, weight variation, drug content, disintegration time, and invitro drug release. A Box–Behnken design was applied to optimize the influence of fenugreek mucilage, isapgol mucilage, and microcrystalline cellulose on key formulation variables. The optimized batch demonstrated desirable hardness, rapid disintegration, and improved dissolution characteristics. Furthermore, ex-vivo permeation studies across goat buccal mucosa confirmed enhanced transmucosal drug permeation, supporting the feasibility of sublingual administration. Overall study establishes that natural superdisintegrants can be effectively utilized in the development of sublingual orodispersible tablets, providing faster onset of action, improved bioavailability, and better patient compliance in the treatment of migraine.

**Keyword:** Eletriptan Hydrobromide, Natural Superdisintegrants, Sublingual Tablets

**PC-398**

**FORMULATION AND VALIDATION OF CURCUMIN-FORTIFIED GROUNDNUT MILK FOR FATTY LIVER MANAGEMENT**

K. Indhumathi*,T. Shri Vijaya Kirubha
Department of Pharmacognosy, Mother Terasa College of Pharmacy
Illuppur, Pudukkottai,Tamilnadu-622 102
indhumathi300705@gmail.com

Curcumin-Fortified Groundnut Milk (CFG-Milk) was developed and validated as a novel functional formulation for the dietary management of non-alcoholic fatty liver disease (NAFLD). Each 200 mL serving was standardized to contain groundnut extract (10 g), soy protein (8 g), microencapsulated curcumin (200 mg), piperine (5 mg) to enhance bioavailability, and soluble fiber (1 g psyllium husk). The formulation was processed by homogenization and pasteurization, with microencapsulation ensuring curcumin stability and palatability. Quality validation confirmed high monounsaturated fatty acid content, retention of bioactive curcumin, low peroxide values, and microbial safety, with aflatoxin screening of peanut raw materials ensuring compliance. Sensory evaluation indicated good acceptability, while stability testing demonstrated minimal phase separation over 14 days under refrigeration. A 12-week pilot clinical validation in adults with imaging-confirmed NAFLD showed that daily consumption of CFG-Milk produced greater reductions in hepatic fat (MRI-PDFF) and significant improvements in liver enzymes (ALT, AST), insulin resistance (HOMA-IR), and lipid profile compared to placebo, without adverse effects. Mechanistically, the formulation integrates hepatoprotective and anti-inflammatory properties of curcumin, bioavailability enhancement by piperine, lipid-modulating effects of groundnut MUFA, and metabolic benefits of soy protein and soluble fiber. These findings suggest that CFG-Milk is a safe, palatable, and effective nutraceutical adjunct for fatty liver management.

**Keywords:** Groundnut milk, Curcumin, Piperine, Non-alcoholic fatty liver disease (NAFLD).

**FORMULATION, OPTIMIZATION, EVALUATION OF PANCHAGAVYA GHRITA ORAL FORMULATION IN THE TREATMENT AND MANAGEMENT OF ARTHRITIS**

Tamanna Barve, Omprakash Pendor, Rashmi Trivedi, Ruchi khobragade
Department of pharmaceutical quality assurance Smt.Kishoritai Bhoyar College of Pharmacy, Kamptee, Maharashtra 441002
barvetamanna@gmail.com

Arthritis is a chronic inflammatory condition characterized by joint pain, swelling, and progressive tissue damage. This study aimed to develop and evaluate an oral multiple emulsion formulation of Panchagavya Ghrita (PGG) for the effective management of arthritis. Multiple

ISBN: 978-81-980623-8-3

emulsions were prepared using a two-step emulsification technique with Tween 80 and Span 80 as surfactants. The formulations were characterized for physicochemical properties including pH, viscosity, particle size, globule size, drug content, in-vitro release, and stability. The optimized batch exhibited a globule size of 5.5 µm, pH values ranging from 6.48 to 7.04 (near neutral), zeta potential of 21.5 ± 0.9 mV, entrapment efficiency of 84.62%, and drug content of 85–91%. Panchagavya Ghrita showed a sharp UV absorption peak at 239 nm, confirming spectral purity, while FTIR analysis revealed characteristic drug peaks with no significant drug–excipient interactions. In vivo evaluation using Complete Freund's Adjuvant (CFA)-induced arthritic rat models demonstrated that PGG multiple emulsions significantly reduced paw inflammation, attenuated pain, and prevented weight loss compared with the control group. These results suggest that the multiple emulsion system enhanced the therapeutic efficacy of PGG by improving bioavailability and sustaining the release of active constituents. Stability studies further confirmed that the emulsions remained physically stable without phase separation or degradation during the test period. Overall, the PGG-based multiple emulsion was found to be safe, stable, and effective, indicating strong potential as a novel oral delivery system for the long-term management of arthritis.

divyanagrikar007@gmail.com

Curcumin, a natural antioxidant with strong neuroprotective effects, is considered a promising candidate for treating neurological disorders such as epilepsy. However, its therapeutic potential is limited by poor bioavailability. This study aimed to develop intranasal curcumin-loaded solid lipid nanoparticles (SLNs) for epilepsy treatment. Nanoparticles were prepared using the microemulsification method and evaluated for particle size, entrapment efficiency, bioadhesion, and in vivo performance. The resulting SLNs were discrete and spherical, with an average particle size of 206.5 nm and a narrow size distribution (polydispersity index: 0.495). They showed high entrapment efficiency 80.64%–98.89%, strong bioadhesion potential 92.60%, and high ex vivo permeation 95.46% without causing morphological damage to goat nasal mucosa. Antiepileptic efficacy was tested using the PTZ-induced seizure model in Sprague Dawley rats, where intranasal administration of curcumin SLNs demonstrated significantly better results than intravenous delivery, effectively delaying the onset and reducing the duration of convulsions. These findings highlight intranasal SLNs as a promising strategy for enhancing curcumin delivery in epilepsy management.

**Keywords:** Curcumin, Solid lipid nanoparticle, Intranasal, Epilepsy, Drug delivery

## FORMULATION AND OPTIMIZATION OF SELF-NANOEMULSIFYING FAST DISSOLVING TABLETS (SNEDDS-FDTS) OF CLONAZEPAM

Geetha Rubyka S A, V. Chandrakala and B. Vasundhara
Department of Pharmaceutics, East Point College of Pharmacy, Bangalore, India– 560049.
rubyka202@gmail.com

Clonazepam, a BCS Class II antiepileptic drug, suffers from poor aqueous solubility and variable absorption, resulting in low oral bioavailability and delayed therapeutic response. To overcome these limitations, a novel formulation was developed by integrating self-nanoemulsifying drug delivery systems (SNEDDS) with fast dissolving tablets (FDTs), combining solubility enhancement with rapid oral disintegration to ensure improved therapeutic efficacy. SNEDDS were optimized using olive oil (oil phase), Tween 80 (surfactant), and PEG 200 (co-surfactant), via pseudo-ternary phase diagrams, producing stable nanoemulsions with globule size less than 100 nm. The optimized SNEDDS was adsorbed onto solid carriers and compressed into fast dissolving tablets containing sodium starch glycolate, crospovidone, MCC, and mannitol, enabling rapid disintegration and effective taste masking. The optimized formulation demonstrated a disintegration time of 18.5 ± 2 seconds and 95% drug release within 12 minutes, compared with only 52% release from conventional tablets, confirming significant improvement in dissolution and bioavailability. FTIR analysis showed no drug–excipient interactions, while stability studies indicated robust physicochemical properties without significant changes. The Clonazepam SNEDDS-FDTs thus represent a pioneering approach for rapid onset of action, enhanced solubility, and improved patient compliance, offering a promising solution for effective epilepsy management, particularly in pediatric and geriatric populations. This demonstrates the potential of SNEDDS-based FDTs as a clinically relevant and patient-friendly strategy for poorly soluble drugs.

**Keywords:** Clonazepam, SNEDDS, fast dissolving tablets, bioavailability, epilepsy management.

## AMPHIPHILIC XANTHAN GUM NANOMICELLAR CARRIERS FOR GASTROINTESTINAL DELIVERY OF CANAGLIFLOZIN

Preeti Lakra and Sabyasachi Maiti
Department of Pharmacy, Indira Gandhi National Tribal University, Amarkantak, Madhya Pradesh-484887, India.
preeti34558@gmail.com

BCS Class IV drugs pose significant challenges in the development of oral drug delivery carriers due to their low solubility and poor permeability. To address these challenges, the design of nanomicellar carriers using nontoxic, biodegradable polysaccharides could be beneficial. In this study, the aldehyde groups were introduced into xanthan gum via TEMPO-mediated oxidation and were further conjugated with heptyl amine to impart amphiphilic properties to xanthan gum. FTIR spectroscopy confirmed the introduction of -CHO groups and the formation of imine (C=N) bonds. The modified polymer could self-organize into spherical nanomicelles as evidenced by TEM images. The critical aggregation concentration (CAC) of the amphiphilic polymer was found to be 4.9 µg/mL in water. The self-association of amphiphilic xanthan gum was driven by Gibbs' free energy (. The hydrodynamic diameter of micelles was in the range of 500- 800 nm. An increase in the drug: polymer weight ratio (1:2, 1:4) resulted in increased canagliflozin entrapment efficiency from 49.44% to 54.4%. Further increase in drug: polymer ratio (1:6) diminished the drug entrapment efficiency to 42.02%. The incorporation of canagliflozin into the polymer resulted in a 5.32-fold, 5.86-fold, and 4.56-fold increase in the solubility of canagliflozin compared to that of pure canagliflozin in water at room temperature. Furthermore, the micellar carriers provided sustained drug release behaviours under simulated gastrointestinal pH. Hence, amphiphilic xanthan gum nanomicelles had the potential to act as solubility enhancers as well as sustained drug release carriers for the antidiabetic drug canagliflozin.

**Keywords**: Canagliflozin, controlled drug delivery, nanomicelles, xanthan gum.

narendrapentu@gmail.com

Psoriasis is a chronic immune- inflammatory triggered skin disorder, characterized by the skin layer scaling, epidermal thickening and keratinocyte hyperproliferation. 125 million population effected by this disease throughout the world. Conventional and biological treatment available in psoriasis is not at all satisfactory with higher side-effects. Phytopharmaceutical approach with flavonoidal hesperidin shows inhibitory effect on the signalling pathways cascade to restrict the release of cytokines like TNF-Alpha, IL-17A and IL-23. Liposomal formulation prepared by the thin film hydration technique and characterized by the particle size, PDI, Entrapment efficiency and drug

ISBN: 978-81-980623-8-3

release patterns. The optimized formulation selected based on critical quality attributes by using Design of experiments (DoE). The desired liposomal formulation with particle size (173nm), PDI (0.327), EE (82.5%) and Drug release (77.85%) incorporated in Carbopol 934 polymer to formulate gel. Molecular docking studies were conducted to know the binding effinity of the hesperidin with the psoriasis evaluated cytokine proteins. Hesperidin shows the highest binding effinity with cytokine TNF-Alpha, ADMET analysis used to measure the pharmacokinetic properties. Psoriasis is a noncurable, life period disorder and the natural dietary flavonoidal hesperidin liposomal gel formulation modify the disease condition with less side effects in safe and effective manner.

## DESIGN AND CHARACTERIZATION OF GINSENOSIDE LOADED CHITOSAN NANOPARTICLES AGAINST HUNTINGTON'S DISEASE

Akila RM and Parthipan S
Department of Pharmaceutics, College of Pharmacy, Sri Ramakrishna Institute of Paramedical Sciences, Coimbatore, Tamil Nadu, India.
akilakathiresan1973@gmail.com

A genetic condition known as Huntington's disease (HD) causes the neurons in some areas of the brain to slowly degenerate and die. The illness also affects brain regions involved in the regulation of voluntary movements. Panax ginseng, a well-known beneficial herb of the Araliaceae family, is an essential medicinal plant that is frequently used therapeutically. The ginsenosides in Panax ginseng help to enhance nerve impulse transmission by requiring damaged neurons. All such medications, however, have restricted delivery since they are unable to cross the blood-brain barrier and enter the central nervous system. The drug carriers that can cross the blood-brain barrier and increase the medication's therapeutic efficacy are chitosan nanoparticles. Medicinal efficacy at the target site is measured using Auto Dock with the standard drug Remacemide, and the blood-brain barrier property of ginsenoside is assessed using QikProp software. This study focuses on the use of ginsenoside-loaded chitosan nanoparticles as a treatment strategy for HD. The powder ginsenoside was characterized using FTIR and UV spectroscopy. The ionic gelation method was used to prepare the nanoparticles, which were then characterized by SEM, particle size, zeta potential, drug entrapment efficiency, in vitro drug release, release kinetics, and in vitro enzyme inhibition studies. The phytoconstituents in the drug gave good blood-brain barrier property of having binding energy between -3 and 1.2. The optimized formulation F4 showed good entrapment efficiency and prolonged drug release for 24 hours.

**Keywords**: Huntington's Disease (HD), Blood-brain barrier (BBB), Chitosan nanoparticles, Ginsenosides, in vitro enzyme inhibition studies. (ACHE)

**PC-405**

## FORMULATION AND EVALUATION OF LIPOSOMAL HYDROGEL FOR THE TREATMENT OF DERMATITIS

Thrupthi D L, Giridhar Kalappa G K, M.P. Venkatesh*
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru-570015, KA, India
trupthidi03@gmail.com

Dermatitis is a prevalent inflammatory skin condition that adversely affects patients' quality of life by causing discomfort, irritation, and increased susceptibility to secondary infections. Conventional topical antifungal therapies, including miconazole creams and ointments, are often limited by inadequate skin penetration, rapid clearance, frequent reapplication, and reduced patient adherence. To overcome these drawbacks, nanotechnology-based drug delivery systems such as liposomal hydrogels have gained attention due to their ability to enhance drug retention, stability, and therapeutic efficacy. In the present research, a miconazole-loaded liposomal hydrogel system was developed and systematically evaluated for the treatment of dermatitis. Miconazole-loaded liposomes, prepared by ethanol injection, provided a protective bilayer environment for the drug, enabling controlled release and improved skin permeability. Incorporating liposomes into a hydrogel matrix prolonged drug retention at the application site while maintaining optimal moisture balance for skin healing. The optimized formulation exhibited favorable physicochemical properties, including a particle size of ~128.31 nm, low polydispersity index (0.204), suitable pH range (5.84–7.35), and excellent spreadability (8.1 cm diameter). In vitro studies confirmed the formulation's ability to improve drug solubility, sustain drug release, enhance skin penetration, and maintain stability under varying conditions. The synergistic combination of liposomes and hydrogel minimized systemic side effects, reduced dosing frequency, and improved patient compliance. The research findings suggested that the miconazole-loaded liposomal hydrogel system represents a promising and patient-friendly alternative to conventional topical formulations, offering targeted, prolonged, and efficient antifungal therapy for dermatitis with minimized adverse effects.

**Keywords:** Miconazole, Liposome, Hydrogel, Dermatitis, Controlled release

**PC-406**

## PREPARATION, CHARACTERIZATION AND EVALUATION OF SOLID LIPID NANOPARTICLES LOADED RIVASTIGMINE

Neha Dubey, Beena Gidwani, Ravindra Kumar Pandey, Shiv Shankar Shukla
Columbia Institute of Pharmacy, Raipur (C.G.)
dubeyneha306@gmail.com

This research aims to optimize the solid lipid nanoparticles using full factorial design to improve the delivery of Rivastigmine, which is used for the treatment of Alzheimer's disease (AD). Solid lipid nanoparticles (SLNs) are attracting the importance for drug developers due to their performance. The outcome of this research will lead to improvements in drug release and solubility of Rivastigmine for better therapeutic effect. Four different methods were used to prepare solid lipid nanoparticles of Rivastigmine. Glyceryl monostearate (GMS) was used as a lipid; Compritol 888, tween 80, and span 40 were used as surfactants, co-surfactants, and stabilizers, respectively. SLNs were evaluated for zeta potential, particle size, polydispersity index, surface morphology, Fourier Transform Infrared Spectroscopy (FTIR), and other parameter. Entrapment efficiency and drug loading were also estimated. Solubility study of rivastigmine in different solid lipids as well as the in-vitro drug release was studies. The particle size of SLNs was found to range between 138.22+ 0.01 nm and 172.79+ 0.23 nm. The zeta potential of the optimized formulation was found to be in the -24 + 0.01mV range, indicating a stable formulation. The Rivastigmine-SLNs showed significant retention in memory when compared with Rivastigmine solution (standard formulation) which may be attributed to the lipid nature and nanostructure of the delivery system that may probably result in more accumulation of drug in the brain to show better effect. The current study concludes that the micro emulsion cooling technique is the best method for patient compliance and stability with all desired characteristics parameters.

## FORMULATION AND EVALUATION OF MOUTH DISSOLVING FILMS OF FLUNARIZINE DIHYDROCHLORIDE USING NATURAL POLYMERS

LAMEESA BANU VP

In the present research, mouth dissolving films of Flunarizine dihydrochloride were developed using natural polymers. The main objective of the study was to enhance the bioavailability and provide a rapid release dosage form of Flunarizine, which suffers from extensive first-pass metabolism and low solubility. Films were prepared by the solvent casting method using pullulan as the primary polymer and varying concentrations of sodium alginate, guar gum, taro gum, and xanthan gum. The prepared formulations were evaluated for surface pH, thickness, folding endurance, weight variation, disintegration time, in vitro release, and stability. FTIR studies confirmed no incompatibility between drug and polymers. Among all formulations, F1 (pullulan and taro gum) showed optimum physicochemical properties, with disintegration time below 10 seconds, acceptable thickness and weight variation, folding endurance above the required limit, drug content of 99.73%, and first-order release kinetics. The study concludes that pullulan and taro gum combination provides a promising natural polymer base for the development of effective buccal films of Flunarizine.

**DESIGN AND OPTIMIZATION OF ANTIPSORIATIC DRUG-LOADED NANOSTRUCTURED LIPID CARRIERS FOR EFFECTIVE PSORIASIS MANAGEMENT**

Kshirsagar Dudheshwar Chandrakant and T.Sudha
Department of Pharmaceutical Chemistry and Analysis, Vels Institute of Science, Technology, and Advanced Studies, Pallavaram, Chennai, Tamil Nadu, India
dudheshwarkshirsagar@gmail.com

Drug delivery methods based on lipids may be able to capture hydrophilic and hydrophobic molecules, increase the bioavailability of medications that are not highly soluble in water, and shield them from premature deterioration. The novel second-generation lipid nanoparticle that functions as a bioactive carrier system is called a nanostructured lipid carrier (NLC). Both hydrophilic and hydrophobic drugs can be transported by nanostructured lipids, which are biocompatible drug carriers. NLCs have a large loading capacity, superior physical stability, good permeability, and are far less expensive than carriers based on polymers or surfactants. Since the majority of antipsoriatic drugs on the market today are BCS class II and IV medications and have solubility and permeability issues, bioavailability is the main factor. This might be fixed by creating NLCs loaded with roflumilast and pimecrolimus. The typical particle diameter for NLCs is between 10 and 1000 nm. Using the melt homogenization method in conjunction with ultrasonication, Roflumilast and Pimecrolimus loaded NLCs were successfully created. Approximately 2-3% of people worldwide suffer from psoriasis, with incidence rates differing greatly between areas and demographics. Some regions of Asia have rates as low as 0.4%, while other regions of Northern Europe claim rates as high as 11%. It is believed that psoriasis affects about 60 million people globally. The range of psoriasis prevalence in India is 0.44 percent to 2.8%. The formulation of the NLCs involved melt homogenization and ultrasonication, yielding nanoparticles with a mean size of 200–400 nm and a negative zeta potential of -26 mV to -30 mV. This confirmed that the nanoscale dimensions were appropriate for topical delivery and had good stability against aggregation. The study's significance lies in its capacity to improve permeability, bioavailability, avoid first-pass metabolism, boost patient compliance, and reduce dosage and size.

**Keywords:** Nanostructured Lipid Carriers, Roflumilast, Pimecrolimus, Melt Emulsification, and Psoriasis.

**TRANSETHOSOMES: A NOVEL CARRIER FOR ENHANCED DERMAL DELIVERY OF CICLOPIROX OLAMINE FOR FUNGAL INFECTION**

S.B. Shirsand*, Adiba Eram, S Shailashri, and Sandhya kore
1Department of Pharmaceutics, HKE'S Matoshree Taradevi Rampure Institute of Pharmaceutical Science, Kalaburagi-585105.
Shirsandss@gmail.com

Now-a-days a tremendous research work is going on to overcome the barrier properties of the skin. Despite of major research and development efforts in this system and the advantages of these routes, low stratum corneum permeability limits the usefulness of topical drug delivery. Transethosomes were developed to improve the solubility, bioavailability and permeability. Ciclopirox olamine is a synthetic, broad-spectrum anti-fungal agent belonging to the hydroxypyridone , useful in the treatment of superficial fungal infections. A distinctive feature of the drug is that no single case of fungal resistance has been reported so far. Ciclopirox olamine loaded transethosomes were formulated by Cold method using different ratios of edge activators (oleic acid, Tween 80 and Poloxamer 407). The transethosomal formulations were evaluated for size, shape, entrapment efficiency and in-vitro drug release. The transethsomes appeared as spherical in shape and size range was found to be 185.0 to 461.5 nm. The entrapment efficiency was found in the range of 70.93 to 80.93% and in-vitro drug release in the range of 65.52 to 80.44 % at the end of 24 hrs. Transethosomes prepared with tween 80 and phospholipids in the ratio of 1: 0.3: 3 were found to be the most effective and were incorporated into 1% carbopol gel. The ciclopirox olamine formulation was loaded into topical gel by incorporating Carbopol 934 as a gelling agent. The formulated gel was evaluated for various physicochemical parameters like appearance, pH, spreadability, viscosity, in-vitro drug release and antifungal activity. The in-vitro drug release study was carried out using phosphate buffer saline pH 7.4 was found to be 71.66 % at the end of 12 hrs. This study has suggested that ciclopirox olamine loaded in transethosomes and incorporated in gel is the superior topical antifungal formulation compared to plain drug gel and marketed formulation.

**DESIGN AND DEVELOPMENT OF NAIL LACQUER LOADED WITH SILVER NANO PARTICLES OF POLY HERBAL EXTRACT FOR SYNERGETIC ANTIFUNGAL ACTIVITY**

SHEELA VERMA

Nail fungus, also known as onychomycosis, is a common infection that can affect fingernails or toenails, causing them to become thick, discolored, and brittle. The infection often starts as a small white or yellow spot under the nail tip and can spread, causing the nail to thicken, change shape, and potentially detach from the nail bed. In the current research work, nail lacquer loaded with silver nanoparticles of alcoholic extracts of Curcuma longa (Turmeric), Carica papaya (Papaya), Ocimum tenuiflorum (Tulsi/Holy Basil), and Azadirachta indica (Neem) were prepared and evaluated for antifungal activity. Individually ethanolic extracts of above said herbal powders were obtained by maceration process. Silver nanopaticles were prepared from these extracts by silver nitrate reduction process. They were evaluated for particle size (PS), entrapment efficiency (EE), polydispersity index (PDI) and Zeta potential (ZP) individually. Various ratios of ethyl cellulose and eudragit RL 100 along with solvents such as ethanol, ethyl acetate and acetone were studied to optimize the composition of the plain Nail lacquer. Measured amount of each herbal nano particles were combined with optimized ratio of ethyl cellulose and eudragit RL 100 to obtain nail lacquer. The obtained formulation was evaluated for pH, Viscosity, spreadability, film thickness and antifungal activity. The results obtained for the above said test parameters for Silver nanoparticles of each herbal extracts, and nail lacquer were well within the acceptance limits. The antifungal activity of the formulation was evaluated in comparison with the reference standard of Fluconazole against Candida albican and results were found to be satisfactory. In conclusion the prepared nail lacquer loaded with silver nanoparticles of polyhedral extract has potential in treating Onychomycosis because of its promising antifungal activity.

**Keywords**: Nail lacquer, Silver nanoparticles, polyherbal, antifungal, Onychomycosis.

**DESIGN AND EVALUATION OF A PH-TRIGGERED REBAMIPIDE IN SITU GEL: A SUSTAINED DRUG DELIVERY STRATEGY FOR DRY EYE DISORDER**

Raheena K.A., Shilpa K.D
Department of Pharmaceutics, Al Shifa College of Pharmacy, Perinthalmanna, Kerala, India-679325
heenuaneesh@gmail.com

In the present study, a Rebamipide-loaded ophthalmic in situ gel was formulated and evaluated for the treatment of dry eye syndrome. The objective was to enhance ocular bioavailability and prolong residence time by overcoming the rapid precorneal drainage of conventional formulations. The in situ gel was prepared by a pH-triggered method using Carbopol 940 and HPMC K4M. Thirteen formulations were designed by varying the polymer concentrations and optimized using Design Expert software. The formulations were evaluated for pH, viscosity, gelling capacity, sterility, in vitro release, and stability. The FTIR analysis confirmed no drug–polymer interaction. The optimized formulation containing 0.6 g Carbopol 940 and 0.4 g HPMC K4M exhibited a pH of 5.0, viscosity of 1274 cP, and a gelling time of 28 seconds. Stability studies over 3 months showed negligible change in viscosity (1274 → 1258 cP), pH (5.0 → 5.1), and gelling time (28 → 29 s). The in vitro release studies indicated sustained drug release over 8 hours. Therefore, the optimized Rebamipide-loaded in situ gel demonstrates potential as a novel ocular delivery system with enhanced bioavailability, prolonged residence time, and reduced dosing frequency, thereby improving patient compliance in the management of dry eye syndrome.

**DEVELOPMENT, OPTIMIZATION AND CHARACTERIZATION OF BERBERINE HYDROCHLORIDE-LOADED TRANSETHOSOMAL GEL FOR ANTI-DIABETIC ACTIVITY**

Afnan K V, Jasnath P and Ajith Chandran
Department of Pharmaceutics, Al Shifa College of Pharmacy, Perinthalmanna, Malappuram, Kerala, India – 679325
afnankv135@gmail.com

Berberine Hydrochloride is a natural alkaloid with established anti-diabetic potential; however, its clinical application is restricted due to poor solubility and limited permeability. To overcome these limitations, a transethosomal gel system was developed to enhance transdermal delivery and sustain drug release. Transethosomes were prepared by the cold method and optimized using a Box-Behnken design with phospholipid concentration, ethanol concentration, and ultrasonication time as variables. The optimized vesicles were evaluated for morphology, particle size, polydispersity index, and zeta potential. Carbopol 940 (0.5–2%) was used to prepare gel formulations, which were assessed for pH, viscosity, spreadability, extrudability, and in vitro release. The optimized gel was further studied for release kinetics, ex vivo permeation, and in vivo anti-diabetic activity in streptozotocin-induced diabetic rats. The optimized formulation showed a particle size of 241.9 nm, PDI of 0.229, and zeta potential of −24.7 mV. Among the gel formulations, 1.5% Carbopol (F4) exhibited the best performance with 81.65% drug release in 24 h, following zero-order kinetics with non-Fickian diffusion. Ex vivo studies demonstrated a permeation coefficient of 0.134 cm/h, while in vivo studies confirmed significant reduction in blood glucose, improved lipid profile, and favorable pancreatic histopathology compared to conventional gel. This study demonstrates that Berberine Hydrochloride-loaded transethosomal gel offers improved release, permeation, and anti-diabetic efficacy, making it a promising candidate for future clinical applications.

**DESIGN AND FABRICATION OF CHILD-FRIENDLY DOSAGE FORM BY QBD APPROACH: AN INNOVATIVE TASTE-MASKING STRATEGY FOR ENHANCED PEDIATRIC COMPLIANCE**

Bhavesh Vanji Chaudhari and Anushka Naresh Patil
Department of Pharmaceutical Sciences, Konkan Gyanpeeth Rahul Dharkar College of Pharmacy and Research Institute, Karjat, Maharashtra, India- 410201
chaudharibhavesh435@gmail.com

In pediatric care, giving bitter drugs, such as diphenhydramine citrate, can be quite difficult. This study developed a pediatric-friendly medicated marshmallow formulation of Diphenhydramine citrate (DPH citrate) using a Quality by Design (QbD) approach to enhance taste masking and compliance. Taste masking was achieved by complexing DPH citrate with Cavasol W7HP (2-hydroxypropyl-β-cyclodextrin) in a 1:5 molar ratio. Implementation of QbD approach was done to defined QTPP and to identify CMA, CPP and CQA in the formulation. A $2^3$ factorial design optimized formulation parameters, focusing on taste evaluation and tensile strength. UV interference was eliminated using a dual-wavelength spectroscopy method. The optimized marshmallows released 506.7 ± 2.03 µg/mL of the drug at salivary pH, below the bitterness threshold and demonstrated a tensile strength of 0.069 ± 0.0012 g. Drug content was 98.68% ± 2.81, with rapid dissolution within 30 minutes. Advanced characterization like DSC and SEM, confirmed formulation quality and stability, making medicated marshmallows an effective, palatable solution for pediatric Diphenhydramine citrate administration.

**Keywords:** Pediatric formulation, Diphenhydramine citrate, Taste masking, Quality by Design (QbD), Medicated marshmallow.

**"PHARMACEUTICAL DEVELOPMENT OF DIANOVA POP: A UNIQUE ANTIDIABETIC MEDICATED LOLLIPOP FOR PATIENT COMPLIANCE"**

Tejaswini R. Bhavar, Sonal S. Bhatkar, Dr. Wasim G. Shaikh, Dr. Amol D. Landge
Shram Sadhana Bombay Trust, Institute of Pharmacy, Bambhori, Jalgaon, Department of Pharmaceutics, Dr. Babasaheb Ambedkar Technological University, Lonere, India

A medicated lollipop is a pharmaceutical dosage form that combines therapeutic drug substances with a confectionery delivery system, typically consisting of a hard candy matrix on a stick for oral administration. There are two types of lollipops: hard lollipops and soft lollipops. Poor medication adherence remains a significant challenge in diabetes management, with compliance rates as low as 50-60% for oral antidiabetic medications. Novel drug delivery systems that improve palatability and patient acceptance are urgently needed, particularly for pediatric and geriatric populations. Stevia, a natural non-caloric sweetener with sugar-free properties, is used as a base in antidiabetic medicated lollipops to provide sweetness without raising blood glucose levels. Stevia supports blood sugar management in diabetic patients while serving as a safe and palatable carrier for active pharmaceutical ingredients. DiaNova Pop represents a promising patient-centric approach to antidiabetic therapy, demonstrating bioequivalence to conventional formulations while significantly improving patient acceptability. The novel lollipop delivery system may enhance medication adherence, particularly in populations with swallowing difficulties or taste aversion. Further clinical studies are warranted to evaluate long-term compliance and glycemic control outcomes.

**Keywords:** Antidiabetic medications, patient compliance, novel drug delivery, medicated confectionery, pharmaceutical innovation.

**FORMULATION OPTIMIZATION AND EVALUATION OF ACETYL KETO BOSWELLIC ACID WITH BASIL OIL NANOEMULGEL FOR ENHANCED TOPICAL ANTI-INFLAMMATORY AND ANTIOXIDANT ACTIVITY**

Sudhanshu Mishr1, Kanchan Kohli2
Faculty of Pharmaceutical Sciences, Mahayogi Gorakhnath University Gorakhpur, Arogyadham,
Balapar Road, Sonbarsa, Gorakhpur, Uttar Pradesh, India, 2730072
Lloyd Institute of Management and Technology, Plot No.-11, Knowledge Park-II, Greater Noida, Uttar Pradesh, India-2013061

Acetyl Keto Boswellic Acid (AKBA) has potent anti-inflammatory, anti-oxidant, and antiarthritic activities. Despite AKBA's strong therapeutic potential, its clinical utility is hindered by poor solubility, low bioavailability, and extensive first-pass metabolism. Given its

ISBN: 978-81-980623-8-3

lipophilicity, suitable molecular weight, and favourable half-life, transdermal delivery offers a promising alternative to enhance systemic absorption and bypass hepatic metabolism for improved therapeutic outcomes. Therefore, the present study focuses on the formulation and characterization of a transdermal nanogel incorporating AKBA and basil oil, aimed at enhancing its therapeutic efficacy, facilitating better penetration and high anti-inflammatory potential. The nanogel was formulated using a high-energy emulsification method and characterized for physicochemical properties including particle size, zeta potential, pH, viscosity, and spreadability. In vitro release studies demonstrated a sustained drug release profile, i.e., 84.69% of the drug released in 24 hours. Also, the AKBA NEGS showed good skin permeability, i.e., 45.44% of the drug permeated through the skin in 24 hours. The AKBA NEGs showed good anti-inflammatory and anti-oxidant activities as compared to the standard Ascorbic acid, as indicated by its promising results in reducing pro-inflammatory cytokines IL6 and TNF-α and free radical scavenging. The AKBA-loaded nanogel systems demonstrated enhanced pharmaceutical performance over conventional formulations. Their potential for transdermal delivery offers a promising strategy to overcome AKBA's bioavailability limitations and achieve sustained therapeutic effects. However, further in vivo and clinical studies are needed to validate long-term safety, efficacy, and skin permeation in humans.

## THE IMPACT OF 3D PRINTING ON DRUG FORMULATION AND PERSONALIZED MEDICINE

Manshree N. Kokane, Mr. Sumit S. Kolte, Dr. Vinod M. Thakre
Nagpur College of Pharmacy, Nagpur, Maharashtra.
manshreekokane3@gmail.com

3D printing has revolutionized pharmaceutical sciences by enabling the development of personalized drug formulations tailored to individual patient needs. Unlike conventional drug manufacturing, 3D printing allows precise control over drug composition, dosage, and release kinetics, leading to optimized therapeutic outcomes. This technology facilitates the fabrication of complex drug geometries, multilayered tablets, and combination therapies in a single dosage form, improving patient adherence and treatment efficacy. One of the key advantages of 3D printing in personalized medicine is its ability to produce customized medications based on a patient's genetic profile, disease state, and metabolic response. This approach minimizes adverse effects, enhances drug bioavailability, and enables dose adjustments without extensive reformulation. Additionally, 3D printing supports on-demand drug production, reducing dependence on large-scale pharmaceutical manufacturing and enabling localized drug fabrication in hospitals and pharmacies. Various 3D printing techniques, including inkjet, stereolithography, and fused deposition modelling, have been explored for pharmaceutical applications. The FDA-approved 3D-printed drug, Spritam®, highlights the clinical viability of this technology. However, challenges such as regulatory hurdles, material limitations, and scalability must be addressed to ensure widespread adoption. Despite these challenges, 3D printing holds immense potential to transform drug formulation and personalized medicine, paving the way for more efficient, patient-centric therapies.

## REVERSING SENESCENCE TO ENHANCE TISSUE REPAIR: THERAPEUTIC POTENTIAL OF A SUSTAINED-RELEASE EPIGALLOCATECHIN GALLATE TRANSDERMAL PATCH IN CHRONIC WOUNDS

Ashwini Somayaji1, Shwetha K2, Anbu Jayaraman1
1Department of Pharmacology, Faculty of Pharmacy, M.S. Ramaiah University of Applied Sciences, New BEL Rd, M S R Nagar, Mathikere, Bengaluru, Karnataka- 560054, India
2Department of Pharmaceutics, Faculty of Pharmacy, M.S. Ramaiah University of Applied Sciences, New BEL Rd, M S R Nagar, Mathikere, Bengaluru, Karnataka- 560054, India

Chronic wounds are often associated with oxidative stress and cellular senescence, which impair the natural healing process. Antioxidants like Epigallocatechin gallate (EGCG) hold promise as senolytic agents by reducing oxidative damage and reactivating senescent cells toward cell division. This study explores the therapeutic potential of a sustained-release EGCG transdermal patch, highlighting its ability to enhance antioxidant activity, restore cellular function, and accelerate wound healing compared to direct EGCG application. EGCG patches were formulated using hydroxypropyl methylcellulose (HPMC) and carboxymethyl cellulose (CMC). Comprehensive evaluations were carried out to determine physical characteristics, FTIR interactions, in vitro drug release, cytotoxicity, anti-senescence effects, and wound healing efficacy. A transgenic mouse chronic wound model was used to validate therapeutic outcomes, including histological and immunohistochemical assessment of senescence- and antioxidant-related markers. The transdermal patch exhibited a stable, translucent appearance with effective drug incorporation. Release studies revealed an initial burst followed by controlled, sustained EGCG release over 8 hours, driven by hydrogen bonding with excipients. This prolonged release enhanced antioxidant activity, reduced senescence, and restored proliferative capacity in vitro. In vivo, the patch showed significant wound contraction (67.46% at day 14) compared to direct EGCG (48.60%) and placebo patches (14.18%). Immunohistochemistry confirmed downregulation of senescence markers and upregulation of antioxidant defenses, consistent with a senolytic and wound-restorative effect. Sustained release of antioxidants like EGCG through a transdermal system offers a novel therapeutic strategy for chronic wounds by extending antioxidant protection, reversing senescence, and promoting effective tissue repair. Future studies should focus on formulation optimization and translational evaluation in clinical populations.

## EFFECT OF PROCESS AND FORMULATION PARAMETERS ON THE OPTIMIZATION OF CUBOSOMES

Priyanka Kumbhar1, Amisha Jogdankar2, Shilpa Shrotriya3
1 Bharati Vidyapeeth (Deemed to be University), Poona College of Pharmacy, Pune, Maharashtra, India 411038.
2 Bharati Vidyapeeth (Deemed to be University), Poona College of Pharmacy, Pune, Maharashtra, India 411038
3 Assistant Professor, Bharati Vidyapeeth (Deemed to be University), Poona College of Pharmacy, Pune, Maharashtra, India 411038

Cubosomes are liquid crystalline nanoparticles that are self-assembled with internal cubic phases that possess a great potential as nanocarriers for targeted and controlled delivery of drugs due to their unique structure. Cubosomes were formulated by using emulsification method followed by probe sonication. Different process & formulation parameters were varied to understand their effect on size, stability and morphology. The effect of process (stirring method, stirring time, sonication method, sonication frequency /and sonication time) and formulation parameters (concentration of GMO and Poloxamer 407) were analyzed. Mechanical stirring formed homogenized dispersion of cubosomes as compared to magnetic stirring. Probe sonication was found to be better than ultra-turrax homogenization, providing smaller particles. Stirring for 30min, 30% sonication frequency, and 15min sonication time were found to be best conditions to achieve nanosized cubosomes with maximum stability. Formulation parameters indicated that 2% glyceryl monooleate (GMO) and 1% Poloxamer 407 provided better formation of cubosomes with appropriate particle size. Optimized formulation showed particle size of 63 ± 5 nm, PDI was 0.14 ± 0.02, and the zeta potential was –33 ± 5 mV. Cubic nanostructures were confirmed by HR-TEM, and sharp Bragg peaks indicated Pn3m cubic phase by SAXS, demonstrating the desired internal crystalline structure. Optimized GMO and Poloxamer 407 concentrations prevent aggregation and provide colloidal stability by striking a balance between structural integrity and steric stabilisation. The selected process variables enabled the preparation of cubosomes with desired particle size and hence a robust platform for advanced drug delivery applications.

**Keywords:** Cubosomes, SAXS, HRTEM, nanostructured carriers, drug delivery

asaredhanashri@gmail.com

Antimicrobial resistance (AMR) represents a serious global health threat, driven by the overuse of antibiotics, leading to the emergence of multidrug-resistant (MDR) bacterial strains. This study aimed to formulate and evaluate an innovative antimicrobial suspension combining cefixime, a third-generation cephalosporin, with cow urine distillate (CUD), a traditional Ayurvedic bio-enhancer recognized for its antimicrobial and antioxidant properties. Cefixime show maximum absorption at 288 nm and 235 nm for CUD and compatibility by FTIR analysis. The optimized suspension exhibited pH of 5.4 ± 0.05, viscosity of 495 cP, sedimentation volume of 1.8 mL/hr and drug content of 93%, confirming stability for oral administration. In vitro antimicrobial testing against resistant strains of Escherichia coli and Klebsiella pneumoniae demonstrated zones of inhibition of 19 mm and 21 mm, respectively, compared to cefixime alone (15 mm and 17 mm). According to the results, cefixime's efficiency increased by the addition of cow urine distillate, allowing for lower dosages and fewer adverse effects. These finding establish the synergistic interaction between cefixime and CUD, enhancing antibacterial activity. The formulated suspension demonstrated stable physicochemical properties and superior antimicrobial efficacy. This study highlights the potential of integrating traditional bio-enhancers with modern antibiotics to overcome AMR, offering a cost-effective and accessible therapeutic alternative.
**Keywords**: Antimicrobial resistance (AMR), Cefixime, Synergistic formulation, Escherichia coli, Klebsiella pneumonia

## FORMULATION AND DEVELOPMENT OF AN AVOCADO AND DARK CHOCOLATE BASED FUNCTIONAL SNACK BAR

Ashwini S. Tore*, M. S. Shirsath, R. B. Pandhare, V. K. Deshmukh
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist-Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
toreashwini63@gmail.com

This study focuses on developing a nutrient-rich functional snack bar with avocado and dark chocolate as major components, supported by oat milk, honey, dates and nuts. The objective was to design a clean-label product combining healthy fats, antioxidants, natural sweeteners, and dietary fiber. The formulation was optimized for texture, taste, and nutritional balance. Avocado provided monounsaturated fats, dark chocolate supplied polyphenols, while dates and honey acted as natural binders. Nuts and oat milk enhanced protein and satiety. The optimized bar demonstrated desirable sensory attributes, stability, and consumer appeal, offering a wholesome and innovative health snack.
**Keywords:** Avocado, Dark chocolate, Oat milk, Dates, Honey, Functional snack bar

## ADVANCING SKINCARE SOLUTIONS: A COMPREHENSIVE STUDY OF HUMECTANTS AND CALAMINE SYNERGY

Sangeetha. S. Nair
College of Pharmaceutical Sciences, Government Medical College, Trivandrum-695011
sangeethasnair2024@gmail.com

Skin hydration and barrier protection are fundamental aspects of dermatological health and cosmetic science. Humectants, both natural and synthetic, play a critical role in maintaining skin moisture by attracting and retaining water molecules. Calamine, on the other hand, is widely recognized for its soothing, anti-pruritic, and protective effects against skin irritation, rashes, and sunburn. This study explores the synergistic potential of combining calamine with humectants to develop innovative skincare formulations. The research aims to (i) evaluate the moisture-retaining efficiency of selected humectants, (ii) assess the compatibility and stability of calamine–humectant formulations, and (iii) analyze their potential benefits in conditions such as eczema, sunburn, and insect bites. Preliminary findings suggest that such combinations not only prolong hydration but also improve soothing action, offering a dual benefit of comfort and protection. As the demand for effective, safe, and consumer-friendly skincare products increases, this study highlights the promising future of calamine–humectant formulations. By bridging hydration and therapeutic relief, this research contributes to the development of next-generation skincare solutions with significant clinical and cosmetic applications.
**Keywords**- Humectant, Skin hydrations, Skin care Product, Calamine, Skin irritations.

## NANOPARTICLE-BASED DRUG DELIVERY IN AMYOTROPHIC LATERAL SCLEROSIS(ALS): RILUZOLE-LOADED PLGA SYSTEMS FOR IMPROVED BLOOD-BRAIN BARRIER TRANSPORT

Jaya Vasavi G1*, Sathesh Kumar.S2, Dr.Shanmugasundaram P3
1*Assistant Professor, Department of Pharmaceutics, School of Pharmaceutical Sciences, Vels Institute of Science, Technology and Advanced Sciences (VISTAS), Chennai-600117, Tamil Nadu, India
2Principal, SNS College of Pharmacy and Health Sciences, Coimbatore, Tamil Nadu, India
3 Professor & Dean, Department of Pharmaceutical Chemistry and Analysis, School of Pharmaceutical Sciences, Vels Institute of Science, Technology and Advanced Sciences (VISTAS), Chennai-600117, Tamil Nadu, India
vasavi.jaya@gmail.com

ALS involves its neurological and clinical manifestations, while the objectives focus on understanding its pathophysiology, improving diagnosis, developing therapies, enhancing supportive care. These efforts aim to improve outcomes and quality of life for individuals affected by ALS. The blood-brain barrier acts as a natural obstacle for preventing delivery of drugs effectively reaching the brain to treat neurological disorders like amyotrophic lateral sclerosis (ALS). One of the FDA-approved medication for the treatment of ALS is derivative of 2-amino-6 [tri-fluoro-methoxy] benzo-thiazole. To enhance its therapeutic potential, researchers loaded drug, known as Riluzole (RLZ), into poly-(lactic-co-glycolic acid) (PLGA) nanoparticles using emulsification solvent diffusion technique.By utilizing design expert software, the prepared polymeric nanoparticles loaded with riluzole are optimized various formulation parameters. Following the assessment of 20 trials were conducted, among them three formulations selected for further investigation. Notably, the analyses revealed there is no significant interactions between Riluzole and excipients used for the formulation. Scanning electron microscopy(SEM) illustrated that nanoparticles exhibited a smooth texture and spherical morphology. Encapsulation efficiency ranges from 42.61 ± 3.61% to 60.02 ± 1.94%, depending on the drug-to-polymer ratios, spanning from 1:1 to 1:4. The data obtained from this study suggest the dosage form's reliable stability and applicability. It is appropriate for a wide range modes of administration from oral to IV injection, as the particle size range supports for the same.
**Keywords**: Polymeric nanoparticles, Blood-brain barrier, Amyotrophic Lateral Sclerosis, Neurodegenerative disorder, Entrapment efficiency.

## FORMULATION, DEVELOPMENT AND CHARACTERIZATION OF TRANSDERMAL PATCH CONTAINING THE ETHOSOMES FOR THE TREATMENT OF MELASMA

Shreya Lokhande, Shirin Bhuyar, Dinesh Biyani, Jayshree Taksande, Milind Umekar
Smt. Kishoritai Bhoyar College of pharmacy, R.T.M.N. University, Nagpur, Maharashtra, India – 441002
lokhandeshreya88@gmail.com

Melasma is a common dermatological disorder characterized by symmetrical, hyperpigmented patches on sun-exposed areas of the skin, particularly the face. Despite being non-life-threatening, it significantly affects the quality of life and remains therapeutically challenging due to its recurrent nature and limitations of conventional treatments. Tretinoin, a retinoid effective in treating melasma, faces transdermal delivery challenges owing to its classification as a BCS Class III drug, having high solubility but low permeability. To overcome these limitations, the present study aimed to develop and evaluate an ethosomal transdermal patch of tretinoin for enhanced skin delivery. Ethosomes, which are ethanol-rich phospholipid vesicles, were chosen for their superior ability to penetrate the stratum corneum and deliver both hydrophilic and lipophilic drugs. Tretinoin-loaded ethosomes were prepared using the thin-film hydration method and optimized using Central Composite Design, focusing on Phospholipon 90G and ethanol

ISBN: 978-81-980623-8-3

concentrations as key variables. The optimized formulation showed high entrapment efficiency (77.24%) and nanosized vesicles (88.9 nm). These ethosomes were incorporated into transdermal patches using polymers HPMC K15 and Eudragit L100 via solvent casting method. Characterization studies confirmed the patches were flexible, uniform, and stable. In-vitro and ex-vivo evaluations demonstrated sustained drug release and enhanced skin permeation compared to conventional formulations. Overall, the study concludes that ethosomal transdermal delivery significantly improves the permeation and therapeutic potential of tretinoin, offering a promising, patient-compliant alternative for the treatment of melasma.

**Keywords:** Melasma, hyperpigmentation, tretinoin, nanocarriers, ethosomes, skin permeation, transdermal drug delivery

**FORMULATION AND DEVELOPMENT OF LIPOSOMES FOR HERPES ZOSTER**

Yogendra Gautam, Krutika Nagpurkar, Rashmi Trivedi, Milind Umekar
Department of Pharmaceutical Quality Assurance, Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Nagpur- 441002.
ymgautam100@gmail.com

The present study focused on the formulation and optimization of capsaicin-loaded liposomes for transdermal delivery in the treatment of Herpes Zoster. Capsaicin, a potent TRPV1 agonist, was encapsulated using the thin film hydration technique with Phospholipon 90H and cholesterol to enhance skin permeability and reduce systemic side effects. A 32 factorial design was employed to optimize key formulation variables-Phospholipon 90H and cholesterol-based on entrapment efficiency and drug release. The optimized liposomes exhibited spherical morphology with a mean particle size of 218.5 ± 0.45 nm and a zeta potential of -14 ± 0.41 mV. The liposomes were incorporated into a Carbopol 934 gel base to develop a topical liposomal gel. In vitro diffusion studies revealed a sustained drug release from the liposomal gel (62.18 ±0.51% at 12 h) compared to plain CAP gel (88.74 ± 0.75% at 4 h). Ex-vivo diffusion and skin irritation studies confirmed enhanced skin permeation and safety. The liposomal gel also exhibited excellent physicochemical stability under accelerated conditions. This formulation holds promise for improved patient compliance and localized treatment of Herpes Zoster with reduced gastrointestinal side effects.

**Keywords:** Capsaicin, Liposomes, Transdermal gel, Herpes Zoster, Thin film hydration

**PC-426**

**FORMULATION AND DEVELOPMENT OF NONOSYSTEM FOR PSORIASIS**

Indranil Deshmukh, shraddha samrit Rashmi Trivedi, Milind umekar
Department of Pharmaceutical Quality Assurance Smt. Kishoritai bhoyar college of pharmacy kamptee Nagpur, Maharashtra 441002
deshmukhindranil@gmail.com

Psoriasis is a chronic, immune-mediated skin condition marked by excessive keratinocyte proliferation and persistent inflammation. Although topical treatments remain the first line of therapy, most conventional formulations are limited by poor skin penetration and undesirable systemic effects. To address these challenges, this study focused on developing a phytosomal gel containing ferulic acid, a natural antioxidant known for its strong anti-inflammatory and protective properties, for improved dermal delivery in psoriasis management. Phytosomes were prepared by varying the drug-to-phospholipid ratios and optimizing sonication parameters to obtain stable nanostructures. Characterization by Differential Scanning Calorimetry (DSC) and Transmission Electron Microscopy (TEM) confirmed the successful formation of discrete, thermally stable, and spherical phytosomal vesicles with nanoscale dimensions. The optimized gel exhibited high entrapment efficiency, controlled drug release, and enhanced skin permeability compared with conventional ferulic acid formulations. Importantly, in vitro anti-psoriatic studies using relevant skin cell models demonstrated that the phytosomal gel significantly reduced both inflammatory markers and keratinocyte hyperproliferation—two key hallmarks of psoriasis. These findings suggest that phytosome-based delivery systems can overcome the inherent limitations of natural compounds and conventional topical therapies. By improving stability, penetration, and sustained release, phytosomal gels may provide a more effective and safer alternative for psoriasis treatment. This approach not only enhances the therapeutic potential of ferulic acid, but also highlights phytosomes as a promising strategy for the topical management of chronic inflammatory skin diseases.

**Keywords:** psoriasis, phytosomal gel, ferulic acid, antioxidant, anti-inflammatory, skin permeability, Intrapment efficiency, controlled release, keratinocyte hyperproliferation.

**PC-427**

**FORMULATION, OPTIMIZATION AND EVALUATION OF MICONAZOLE NIOSOMAL GEL**

Athira Balachandran, Daisy P.A, Iwin Thomas
Department of Pharmaceutics, St. Joseph's College of Pharmacy, Cherthala, Kerala, India - 688524
aathirabalachandran03@gmail.com

Fungal infections of the skin are one of the often faced with dermatological diseases in worldwide. Topical therapy is an attractive choice for the treatment of the cutaneous infections due to its advantageous such as targeting of drugs to the site of infection and reduction of the risk of systemic side effects. This study was to investigate the feasibility of using niosome as a transdermal drug delivery system for Miconazole. Miconazole is an imidazole antifungal agent used in the treatment of candida infections, fungal infections. The aim of this present work is to formulate miconazole niosomes by two different methods (thin film hydration and modified ether injection method) and to evaluate optimized niosomes in carbopol gel (two factorial design methods). Miconazole niosomes were prepared by varying the cholesterol and surfactant ratios. Each formulation was evaluated for percentage of drug entrapment and for their vesicle size. Niosomal formulations were optimized by two level factorial using stat ease design expert 10 software. Eight runs were done with two methods from which most appropriate were selected by range of vesicle size (0.30µm) and maximum entrapment (87.9%). With the optimized formulation niosomal gel were prepared using carbopol 940 as gelling agent. Thin film niosomal gel showing 93.6% release after 7hrs. From this thin film hydration niosomes were selected for further kinetic studies and stability studies. Hence thin film hydration method is better when compared with modified ether injection method for miconazole niosomal gel application.

**Key words:** Niosomes; miconazole; topical therapy.

**PC-428**

**FORMULATION AND IN VITRO EVALUATION OF GELATIN-BASED DICLOFENAC GUMMIES: A NOVEL PEDIATRIC ORAL DOSAGE FORM**

A. Mohammed Riyas, M. Amudha and V. Ganesan.
Pannai college of pharmacy, Affiliated to the Tamil Nadu Dr. MGR Medical University, Chennai, Tamilnadu-600032
riyasfiyas11@gmail.com

Diclofenac sodium is a bitter-tasting nonsteroidal anti-inflammatory drug (NSAID) with analgesic, anti-inflammatory, and antipyretic properties. However, its unpleasant taste, significant first-pass metabolism, and limited bioavailability reduce pediatric patient acceptability. This study aimed to develop a novel gelatin-based chewable gummy formulation designed to improve palatability, ease of administration, and pediatric compliance. The formulation was prepared using diclofenac sodium as the active ingredient, gelatin as a natural polymer gelling agent along with sucrose, sorbitol, citric acid, sodium benzoate, flavoring, and colorants. Two separate solutions were prepared: a 1:1 mixture of sorbitol and sucrose with a water-to-sorbitol ratio of 2:1, and a gelatin solution heated to 60°C. These were combined with excipients to form the gummies. Pre-formulation studies involved bulk characterization and solubility analysis, including determination of pKa and partition coefficient. Post-formulation evaluations included texture analysis, swelling index measurement, in vitro dissolution testing, and drug release kinetics assessment. Most formulations released 95% of the drug within 1 hour, following first-order kinetics consistent with immediate-release dosage forms. The diclofenac gummies demonstrated rapid disintegration, improved palatability, and effective drug release profiles, making them a promising pediatric dosage form that enhances treatment adherence and therapeutic outcomes.

ISBN: 978-81-980623-8-3

**Keywords:** Diclofenac sodium, Gelatin Gummies, pediatric dosage form, Palatability enhancement, chewable formulation.

**MICRONEEDLE PATCHES: A NOVEL APPROACH FOR ANEMIA TREATMENT**

M.Mohamed Riyash*, A.Gayathri, T.Shri Vijaya kirubha
Department of Pharmacology, Mother Terasa College of Pharmacy
Illuppur, Pudukkottai, Tamilnadu – 622 102.
mohamedriyash29@gmail.com

Anemia is a serious health problem that affects many peoples around the world, specially in developing countries. Traditional treatments like oral iron tablets and intravenous injections often have problems such as low absorption, stomach pain, and poor patient compliances. Recently, microneedle patches has been looked at as a new and better way to treat anemia.These small patches contains tiny needles which can deliver iron or other drugs direct into the skin without much pain. It bypass the digestive system and helps to avoid common side effects. Also, it can be used by the patient themself, which make it more easy and increase the chance they will follow treatment. Research have shown that microneedle patches can increase iron level faster and safer than some traditional methods. They can also be used to give other anemia-related medicines like vitamin B12 or erythropoietin. But still, there are some challenges. Also, making the patches need special materials, technology, and careful handling during production and storage. Also, these patches can be keep in normal temperature which is helpful for village areas where fridge is not available.It also may help in giving not just iron but also other things like folic acid or B12. Some early researches showing that patients got better hemoglobin levels with less problems. In future, this may be good option for big health programs in poor countries. More studies is still needed but microneedle patches is looking like a very hopeful and useful way to treat anemia.

**DEVELOPMENT OF A NATURAL WATER PURIFICATION TABLET USING INDIAN MULBERRY (MORINDA TINCTORIA) BARK, ACTIVATED CARBON, AND CLAY**

Surapaneni Krupa Lahari* and T. Sravani
Department of Pharmaceutics, V. V. Institute of Pharmaceutical Sciences, Seshadri Rao Knowledge Village, Gudlavalleru, Andhra Pradesh, India-521356
krupalaharisurapaneni@gmail.com

Access to safe drinking water remains a global challenge, particularly in rural areas where conventional purification methods are often unavailable or expensive. This study proposes a novel, low-cost, and eco-friendly water purification tablet formulated using Indian Mulberry (Morinda tinctoria) bark powder, activated carbon, and clay. The bark powder, rich in natural antimicrobial compounds, synergizes with activated carbon and clay to remove microbial contaminants, turbidity, and chemical impurities. Tablets were prepared by blending the powders in optimized ratios (50:30:20) and compressing them into small, portable units. Evaluation parameters included solubility, physical stability, microbial reduction (total coliforms and E. coli), turbidity removal, and pH adjustment. Results demonstrated significant reduction in microbial load and turbidity, with the treated water exhibiting acceptable taste and pH, confirming the tablet's effectiveness as a safe drinking water solution. This innovative formulation leverages locally available natural resources and provides a practical approach for rural water purification, offering a sustainable alternative to chemical-based treatments.

**Keywords:** Morinda tinctoria, water purification tablet, natural antimicrobial, activated carbon, clay

**SUSTAINABLE PHARMACEUTICAL DEVELOPMENT UTILIZING VIGNA MUNGO POLYMER MICROBEADS**

M. Rakshitha and P. Raveesha
Department of Pharmacognosy V. V. Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh India. 521356
Rakshitamotepalli@gmail.com

This study explores the potential of Vigna mungo gum as a sustainable and innovative natural polymer for developing microbeads for the controlled delivery of vildagliptin, a widely used antidiabetic agent. Unlike conventional natural polymers, Vigna mungo gum offers unique biocompatibility, biodegradability, and an eco-friendly production process, distinguishing it as a superior candidate for drug delivery systems. Microbeads were prepared by combining Vigna mungo gum with sodium alginate and inducing gelation using calcium carbonate. Scanning electron microscopy (SEM) revealed a rough, porous microbead surface, advantageous for drug encapsulation and controlled release. Drug release studies demonstrated sustained release kinetics, highlighting the effectiveness of this formulation. These findings underscore the novelty of Vigna mungo gum as a promising platform for antidiabetic drug delivery, providing a sustainable alternative to existing polymer systems.

**Keywords:** Vigna mungo; biopolymer; microbeads; diabetes mellitus; ionotropic gelation.

**INFLUENCE OF KLUCEL HF AND KOLLIPHER P407 ON CONTROLLED RELEASE FLOATING MATRIX TABLETS OF MEBEVERINE HCL FOR IRRITABLE BOWEL SYNDROME**

J.Rupadevi and T.Balakrishna,
Department of Pharmaceutical sciences, V.V. Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh, INDIA. - 521356,
rupadevijogi2005@gmail.com

In the current study, a drug named Mebeverine was used for the design of FDDS. One class of drug called an antispasmodic is mebeverine. It helps to relieve muscle spasms. It can help relieve unpleasant stomach cramps caused by irritable bowel syndrome (IBS) or other illnesses. We made mebeverine HCL floating matrix tablets by using the direct compression method with Klucel HF and Kollipher P407.. The matrix tablet formulation did not allow drug release of 12 hours in the formulation F1 - F3 that included klucel in it. The percentage of drug released ranged from 59.36 to 84.69%.In formulations F4–F6, which included Kollipher P407 63.55 to 87.33%, The drug release could not be extended for more than 12 hours using the matrix tablet formulations. The drug release was prolonged to 95.66% at 12 hours by the optimised F7 formulation, which contained klucel HF and Kollipher P407 in different ratios as rate-controlling polymers. All of the matrix tablet formulations had release exponents (n values) between 0.474 and 0.830, the drug release mechanism exhibited non-Fickian diffusion characteristics. This suggests that the release process involved a complex interplay of factors. In particular, the drug came out of the matrix tablets by a process called diffusion, which carried it over the polymeric matrix. Also, the peptides were released when the polymer matrix dissolved. FTIR and DSC analyses of the drug's Polymers optimised formulation F7 revealed that the formulation is fairly stable.

**Keywords:** Controlled release, Floating matrix tablets, Klucel HF, Kollipher P407, Mebeverine.

Synthetic dyes were extensively used to develop marketable.The Anthocynin that occurs in Hibiscus has attracted interest as a natural coloring material source to synthetic dye. Nevertheless, natural colorant usage in available is restricted because its stability to temperature, oxygen, pH, phyoto and colour deteriorated during storage is low. The aim of the present investigation was to develop lipsticks using Anthocynin and assess feasibility as a natural colourant for lipstick development and investigate its stability over one-month storage interval. Anthocynin in this study was isolated from fresh flowers of Hibiscus using water by compression method. Anthrocynin pigment obtained was utilized to formulate lipsticks with standard lipstick formula and the formulated lipsticks were kept under light or dark condition for one-month storage period for stability study. Physico-

ISBN: 978-81-980623-8-3

chemical attributes of the formulated lipstick such as breaking point, surface irregularities, spreadability, skin irritation test, perfume stability, uniformity and homogeneity were investigated and compared to marketable lipsticks. Stability of formulated lipstick determines to be stable under dark condition whereas color loss is higher for lipstick in light condition.However, because of low pigmentation from method, Anthocynin is recommended incorporate in to lip balm application. In this research study, Anthocynin has been proven to be ideal substitute for synthetic dye in cosmetics industry for lip balm application.

**Keywords:** Anthocynin, Hibiscus, Lipsticks

Arthritis is a chronic inflammatory disorder that requires long-term therapy and is often associated with gastrointestinal and systemic side effects when treated with oral drugs. Upadacitinib (UPA) is a selective Janus kinase (JAK1) inhibitor which is highly effective in the treatment of rheumatoid arthritis. However, when UPA is administered orally, it exhibits first-pass metabolism and certain toxicity. This study aims to overcome these limitations by formulating and developing an Upadacitinib niosomal gel for topical delivery. Niosomes were prepared using the thin film hydration method using Span 60 and Cholesterol at different concentrations and evaluated with respect to particle size, entrapment efficiency(%EE) and zeta potential (ZP) The estimated niosomes exhibited an average particle size of 167nm, an EE of 88.37%, and a ZP of -14 mV. The niosomes were then incorporated into a poloxamer 407 gel base to obtain a stable niosomal gel which was then evaluated to determine various physicochemical characteristics. The optimized niosomal gel had a pH of 7.3 which showed better skin penetration, spreadability, and viscosity. Furthermore, the drug content of the niosomal gel was determined to be 98.75%. This niosomal gel loaded with UPA showed prolonged action than oral formulations. This study suggests that UPA-loaded niosomal gel is potentially effective in reducing inflammation, along with the reduction in systemic exposure and associated side effects.

**Keywords:** Arthritis, Upadacitinib, Niosomes, Niosomal gel

**NANOPARTICLE-BASED FORMULATIONS OF CORDYCEPIN: ENHANCING STABILITY AND PULMONARY TARGETING**

Shrikant W. Bute, Milind J. Umekar, Amol A. Tatode Mohammad Qutub
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra 441002
shrikantbute@gmail.com

The nucleoside analog cordycepin, which was isolated from Cordyceps militaris, exhibited remarkable therapeutic potential due to its antioxidant, anti-inflammatory, and immunomodulatory activities. However, its poor retention in the lungs, low bioavailability, and rapid enzymatic degradation significantly compromise its therapeutic utility against pulmonary diseases. Recent advances in nanoparticulate delivery system technologies like inorganic systems, polymeric nanoparticles, and lipid-based carriers have provided new opportunities for enhancing cordycepin's stability and targeted delivery to pulmonary tissues. This review addresses advanced formulation approaches, immunomodulatory mechanisms, and intracellular trafficking pathways with emphasis on their therapeutic effect in idiopathic pulmonary fibrosis (IPF), asthma, chronic obstructive pulmonary disease (COPD), and acute respiratory distress syndrome (ARDS). Nanoparticles enhance intracellular transport and minimize degradation by promoting receptor-mediated endocytosis, caveolae-mediated uptake, and macropinocytosis. In addition, nanoparticle-based systems target AMPK/mTOR and Nrf2-mediated antioxidant signaling and suppress key inflammatory processes such as NF-κB and NLRP3 inflammasome activation. Despite promising preclinical outcomes, there remain challenges with enhancing endosomal release, lung-specific targeting, and prolonged nanoparticle formulation safety. To efficaciously translate cordycepin delivery through nanoparticles into therapeutic uses for pulmonary conditions, this article integrates recent advancements and proposes potential future avenues of research.

**Keywords:** Cordycepin, pulmonary drug delivery, nanoparticles, lung-specific targeting, immunomodulation.

**DEVELOPMENT OF LORNOXICAM NANOPARTICLES FOR ENHANCED SOLUBILITY AND BIOAVAILABILITY OPTIMIZED VIA HIGH PRESSURE HOMOGENIZATION**

Lekhana Gowda K and Vazir Ashfaq Ahmed
Department of Pharmaceutics, Ikon Pharmacy college, Bidadi, Ramanagara[T&D], Karnataka, India-562109
lekanagowda7@gmail.com

The aim of this work is to formulate lornoxicam nanoparticles via the emulsion diffusion method combined with high-pressure homogenization to enhance the solubility of this poorly water-soluble drug and improve its bioavailability. This study employs a robust approach by producing four nanoparticle formulations using Tween 80 as a stabilizer, subsequently processed by spray drying to yield finely dispersed particles optimized for tablet compaction. These formulations are comprehensively evaluated using XRPD to assess crystallinity, SEM for morphology, particle size distribution for uniformity, drug content assays for dosage accuracy, and in vitro dissolution profiling under physiological conditions. Nanoparticulated compacts are prepared via direct compression with various excipients while maintaining a consistent tablet weight to ensure manufacturability and weight uniformity. FTIR studies verify the absence of drug–excipient incompatibilities, confirming formulation stability. Pre- and post-compression evaluations demonstrate compliance with pharmacopoeial standards for hardness, friability, weight variation, and content uniformity. Among the formulations, F3 delivers the highest drug release of 98.64%, nearly matching the marketed product Mobic, which achieves 98.72% release within 60 minutes. These in vitro results confirm that combining high-pressure homogenization with spray granulation is an efficient method for developing nanoparticle formulations of BCS Class II drugs with enhanced solubility and accelerated dissolution rates. In conclusion, the F3 formulation of lornoxicam nanoparticle-based tablets demonstrates superior performance over conventional formulations, potentially improving patient compliance through enhanced dissolution, faster therapeutic onset, scalable manufacturability, and formulation quality.

**Keywords:** Formulation; FTIR studies; In vitro drug release; Lornoxicam; nanoparticles.

**HYDROTROPY ASSISTED SOLUBILITY IMPROVEMENT AND DRUG FORMULATION STRATEGIES**

Urwashi Baghele, Gajanan Sormare, Nishant Awandekar
Smt. Kishoritai bhoyar college of pharmacy, Kamptee, nagpur, Maharashtra -441002
urwashibaghele2018@gmail.com

Enhancing the solubility of poorly water-soluble drugs is a critical challenge in both the screening of new chemical entities and pharmaceutical formulation research. Several techniques are used to improve the aqueous solubility of poorly water-soluble drugs, with hydrotropic solubilisation being one of the prominent methods. A hydrotropic agent is a substance that enhances the solubility of hydrophobic compounds in water based solutions. It is one of the solubility enhancement techniques which enhance solubility in mani folds with the use of hydrotropes like sodium citrate, PEG-600, sodium benzoate, urea, niacinamide, etc. In the present study, efforts were made to increases that solubility of poorly soluble drug belonging semi-synthetic macrolide antibiotic category and develop and optimize fast-disintegrating tablets. Different combinations of sodium starch glycolate and cross carmellose sodium were used as super disintegrant. A two factors three levels 32 factorial design was used to optimize the formulation. Nine formulation batches were prepared accordingly. Two factors i.e. two independent variables viz. sodium starch glycolate and cross carmellose sodium, were taken with three levels (+1, 0, -1). All the active blends were evaluated for pre- compression parameters like angle of repose(20°), Hausner ratio(1.10), etc. and the tablets were evaluated

ISBN: 978-81-980623-8-3

for post- compression parameters (weight variations, hardness(3kg/cm2), friability, disintegration time(40sec) and invitro dissolution). The optimum Hydrotropic solid dispersion was further evaluated for XRD showing significant results.

**Keywords:** Hydrotropy, Solubility enhancement, factorial design, fast disintegrating tablets.

**DEVELOPMENT AND EVALUATION OF NAIL DRUG DELIVERY SYSTEM OF ANTI-FUNGAL DRUG**

Pruthvi J R and Vazir Ashfaq Ahmed
Department of Pharmaceutics, Ikon Pharmacy College, Bidadi, Ramanagara [T&D], Karnataka, India -562109
pruthvijrpruthvijr@gmail.com

The study develops a nail lacquer formulation for antifungal drug delivery to improve physicochemical properties that influence permeation through the nail plate. Effective topical treatment of onychomycosis requires achieving sufficient drug concentrations within and across the nail plate to reach local target sites. Therefore, the antifungal drug is combined with a suitable delivery method that enhances its diffusion into the nail bed to levels above the minimum inhibitory concentration (MIC) needed to inhibit fungal growth. The formulations are prepared using a simple mixing method and evaluated for non-volatile content, gloss, smoothness of flow, drug diffusion, and percentage drug content. Among various formulations, the F4 formulation contains 2% oxiconazole, 6% nitrocellulose, 1% ethyl cellulose, 15% salicylic acid, 10% propylene glycol, and 10% 2-H β-cyclodextrin. This formulation exhibits optimal non-volatile content, superior drug release, accurate drug content estimation, and effective zone of inhibition against fungal pathogens. F4 achieves 93.2% drug release within 12 hours, indicating efficient delivery. In vitro ungual permeation studies demonstrate a strong in vitro–in vivo correlation, confirming effective penetration through the nail barrier. Stability studies show that the formulation remains stable after one month at 40±2 °C. Thus, this nail lacquer system effectively enhances antifungal therapy for onychomycosis.

**Keywords:** Onychomycosis, nail lacquer, nail growth, stability.

The anti-cancer medication methotrexate has a short biological half-life, limited solubility, and low bioavailability. The goal of this project is to create a methotrexate oral sustained release nanoformulation. Methotrexate To create a suspension, caragenan-coated particles were made and described. Using the drug released analysis, gel characterisation, particles size analysis, and Zeta potential, the ideal suspension was determined. The coated particles were enclosed in an aqueous hydrodynamic gel of eudragitS100 with carrageenan lambda or animated tamarind gum in excess. Interestingly, when the F5 formulations come into contact with 0.1 normal hydrogen chloride, the sustained released formulation had the best capacity to create a cohesive insoluble sedimented gel. Additionally, this formulation included methotrexate nanoparticles coated with carrageenan and eudragit s100, as well as nanosuspensions (86.7±2.00 nm). The formulation of methotrexate nanoparticles was authorized following antitumor evaluation against HCT-116 cells because to its contribution to the sustained released properties, sensitivity, and time-dependent efficacy. It is recommended to use the X-ray study examination on albino wistar rat, which shows successful delivery, as a long-acting therapy that could protect the drug and nanoparticles through the polymer coating of the released nano drug particles, in situ gel formation in the colonrectal region, and a PH selective and sustained released matrix.

**Keywords:** Methotrexate, Carrageenan, In-situ gel, Sustained released, colorectal cancer

**FORMULATION AND EVALUATION OF SALICYLIC ACID CUBOSOMAL GEL**

B. Vasundhara, Arshitha.S and S.A Geetha Rubyka
Department of Pharmaceutics, East Point College of Pharmacy, Bangalore, India -560049
vasundharabapanapalli970@gmail.com

This study focuses on the formulation and evaluation of a cubosomal gel containing salicylic acid, offering a novel transdermal drug delivery approach for acne treatment. Transdermal gels are favored for their ease of application, non-toxicity, and effective skin permeation. Cubosomal dispersions were prepared using glyceryl monooleate as the lipid phase and poloxamer 407 as a non-ionic surfactant via the top-down method. The dispersions were characterized for morphology, particle size, zeta potential, entrapment efficiency, drug content, and in-vitro drug release. Among them, formulation D2 exhibited cubic structures with well-separated particles, a particle size of 235.4 nm, zeta potential of –17.2 mV, 70 ± 0.4% entrapment efficiency, 91.04 ± 0.07% drug content, and 87.33 ± 0.031% in-vitro drug release. D2 was incorporated into a gel base using gond katira, a natural gum. The resulting gel showed a pH of 5.4, transparent appearance, 400 g extrudability, 6.7 cm spreadability, 80 ± 0.9% drug content, and 68.31 ± 0.026% in-vitro drug release. Both the dispersion and formulated gel followed a sustained release pattern. The cubosomal gel demonstrated improved stability, controlled drug release, and enhanced therapeutic efficacy compared to conventional formulations. Gond katira further contributed to the gel's cosmetic appeal and functional properties. Overall, this work highlights cubosomes as a promising, patient-friendly, and clinically relevant strategy for transdermal delivery of anti-acne agents, paving the way for innovative dermatological treatments.

**FORMULATION AND EVALUATION OF EFFERVESCENT DENTAL CARE TABLETS VIA DIRECT COMPRESSION**

Bhagyashri Patil and Sadhana Raut
Dep. Of Pharmaceutical Quality Assurance, Sinhagad collge of pharmacy, vadgaon bk. Pune, MS, India 411041.
bhagyashri.ndb@gmail.com

The objective of this research paper is to compile and summarize scientific data supporting techniques for mechanical oral hygiene that can help prevent periodontal diseases. This review article highlights recent developments in excipients used in the pharmaceutical industry's direct compression tablet production process. The formulated effervescent dental care tablet is rapid-acting, travel-friendly, and fluoride-free. The tablet formulation is based on the physicochemical properties of a mixture containing 4% polyethylene glycol 6000 and 0.1% sodium stearate fumarate, used as a lubricant for direct-compression vitamin C tablets. The maximum friability of the formulation was determined to be 0.922 for T4

**FLOATING–PULSATILE CALCIUM ALGINATE BEADS OF KETOPROFEN: A NOVEL CHRONOTHERAPEUTIC APPROACH**

Gowri Prasad G S. Boby Johns G. Lekshmi B R
Department of Pharmaceutics. St. Joseph's College of Pharmacy, Cherthala, Kerala, India 688524
gowriprasad346@gmail.com

Chronotherapeutic drug delivery systems aim to synchronize drug release with circadian variations of disease symptoms. In rheumatoid arthritis, morning stiffness and pain require a dosage form that provides a defined gastric lag phase followed by rapid intestinal release. In this study, a multiparticulate floating–pulsatile drug delivery system of ketoprofen was developed using hollow calcium alginate beads. The beads were prepared by ionotropic gelation employing sodium alginate and acidified calcium chloride as cross-linking agent, designed to remain buoyant in gastric fluid and trigger time and site-specific release. The formulation was optimized to achieve a 6 hrs gastric lag phase with minimal drug release. The optimized beads exhibited high entrapment

ISBN: 978-81-980623-8-3

efficiency (94.68%), buoyancy for 6 hrs, and a biphasic release profile characterized by 11.09% release in acidic buffer followed by 97.78% release within 2 hrs in phosphate buffer. Evaluation included yield, particle size, swelling index, buoyancy, in-vitro drug release, and ex-vivo permeation. FT-IR, DSC, and UV analyses confirmed drug–polymer compatibility, while SEM revealed hollow spherical morphology. Release kinetics followed Higuchi and Kim–Fassihi models, suggesting diffusion-controlled pulsatile release with anomalous (non-Fickian) transport. Ex vivo permeation studies indicated satisfactory intestinal absorption. The study concludes that hollow calcium alginate beads of ketoprofen provide an effective floating–pulsatile release system suitable for chronotherapy of rheumatoid arthritis. This approach ensures site- and time-specific drug delivery, enhances therapeutic efficacy, improves patient compliance, and shows promise for industrial scalability.

## FORMULATION AND EVALUATION OF FLOATING MICROSPHERES OF PANTOPRAZOLE SODIUM

G. Neha, Dr. Praveen Raj R, Naidulekha Aswani
Department of Pharmaceutics, St. Joseph's College of Pharmacy, Cherthala, Kerala, India- 688524.
nehagnair2002@gmail.com

Floating microspheres are an effective oral drug delivery system designed to achieve prolonged and controlled release, improve bioavailability, and enhance gastric retention. These microspheres remain buoyant over gastric contents for an extended period due to their low density, thereby increasing the residence time in the stomach. The present study aimed to develop and evaluate floating microspheres of pantoprazole sodium. Microspheres were prepared using a modified quasi-emulsion solvent diffusion method with Eudragit RL 100 as the polymer. Six different formulations were developed and evaluated for percentage yield, particle size, drug loading capacity, in vitro buoyancy, surface morphology (by scanning electron microscopy), and drug release profile. Results indicated that increasing the concentration of Eudragit RL100 significantly influenced particle size, percentage yield, buoyancy, and drug release, with optimal outcomes achieved at a specific drug-to-polymer ratio. The findings suggest that pantoprazole sodium-loaded floating microspheres can be successfully formulated as a controlled release dosage form, offering reduced dosing frequency and an effective alternative to conventional formulations.

## FABRICATION AND EVALUATION OF NOVEL ECO-FRIENDLY NATURAL SANITARY NAPKINS: A COMPARISON WITH COMMERCIAL PRODUCT

Jeevana Sivagnanam* Dharanika.V , Arthi.A
Department of Pharmacy Practice ,PPG College of Pharmacy ,Saravanampatti-641035 Coimbatore, Tamil nadu, India.
arthianbalagan872@gmail.com

The growing need for sustainable and health-conscious menstrual hygiene products has prompted the development of biodegradable alternatives to conventional sanitary napkins, which often contain plastics and synthetic chemicals. This project aimed to fabricate and evaluate eco-friendly sanitary napkins using natural fibers such as sugarcane bagasse and banana fiber, combined with antimicrobial herbal extracts including Curcuma longa (turmeric) and Azadirachta indica (neem). A multi-layered napkin was developed using a cotton top sheet, an absorbent core made of sugarcane bagasse or banana fiber, herbal powders for antimicrobial action, and a biodegradable backing layer. Performance evaluations included absorbency, wicking, retention capacity, and pathogen resistance, and were compared with commercial napkins. Sugarcane bagasse-based napkins exhibited the highest absorbency, while banana fiber provided better retention. Sugarcane bagasse napkin shows better antimicrobial activity then banana fibre napkin. Compared to commercial products, the ecofriendly napkins were safer and biodegradable. In conclusion, the developed herbal sanitary napkins offer a promising solution for effective and sustainable menstrual hygiene management, especially in low-resource settings. They address environmental concerns and promote women's health by utilizing natural, renewable materials with added antimicrobial benefits.

**Keywords:** Biodegradable sanitary napkins, natural fibres, sustainable menstrual hygiene, sugarcane bagasse, banana fiber

## DESIGN AND OPTIMIZATION OF QUERCETIN AND GINGER-GREEN TEA EXTRACT LOADED MICROSPONGE GEL FOR ARTHRITIS

Nanditha M, M. Padmasree, B A Vishwanath
Department of Pharmaceutics; Aditya Bangalore Institute of pharmacy Education & Research, Yelahanka, Bangalore, Karnataka, India-560064
nandithamnanditham34@gmail.com

Millions of people worldwide suffer from arthritis, a chronic inflammatory disease characterized by joint stiffness and pain. Conventional treatments are often limited by systemic side effects and poor bioavailability. This study aimed to design and optimize a topical gel based on microsponge technology incorporating quercetin, ginger, and green tea extract to overcome these limitations. Microsponge delivery systems offer several advantages for localized therapy, including improved stability, controlled drug release, and enhanced dermal penetration. Microsponges were prepared using the quasi-emulsion solvent diffusion method and loaded into a Carbopol-based gel. The formulations were evaluated for drug content, particle size, zeta potential, entrapment efficiency and gel's viscosity, pH, and in vitro drug release profiles. The optimized formulation exhibited a mean particle size of 61 nm and a stable zeta potential of 42.3 mV. Entrapment efficiency were found to be 89.3% for quercetin, 94.6% for ginger, and 77.19% for green tea extract. In vitro release studies shown that controlled drug release with gradual release reaching 94.8% for quercetin, 94.03% for ginger, and 91.56% for green tea. The gel exihibited viscosity of 3600 cps and a skin-compatible pH of 5, making it suitable for topical application. The present research work may be a promising approach for developing a patient-friendly and effective topical therapy for the treatment of arthritis.

**PC-446**

## DEVELOPMENT AND OPTIMIZATION OF RISPERIDONE LOADED LIPID NANOCAPSULES FOR ENHANCED SOLUBILITY, SUSTAINED RELEASE, AND BIOCOMPATIBILITY

Mahesha K 1, Mahalaxmi Rathnanand 1
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal, India - 576104
mahesha.mcopsmpl2023@learner.manipal.edu

Schizophrenia is a disabling and chronic psychiatric disorder that considerably reduces the quality of life of patients. The therapeutic efficacy of Risperidone (RSP) is limited by its poor oral bioavailability and relatively short elimination half-life. In the present investigation, lipid nanocapsules (LNCs) were used as a new carrier system to improve the solubility and systemic bioavailability of RSP. A preliminary oil screening was carried out, followed by optimization of the formulation based on a central composite design to identify relationships between formulation variables and key quality attributes. The optimized RSP-LNCs were rigorously examined for particle size, polydispersity index (PDI), zeta potential, encapsulation efficiency (%EE), and in vitro drug release. DSC and FTIR studies established successful loading of RSP into the nanocapsule matrix. The optimized formula had a mean particle size of 256.8 nm, PDI of 0.309, zeta potential of -48.1 mV, and encapsulation efficiency of 77.62%. In vitro dissolution showed a sustained release profile and about 94% cumulative drug release in 24 h. In vitro Cytotoxicity assay showed that the optimized RSP-LNCs had high cell viability at therapeutic levels, which was evidence of good biocompatibility. These results indicate that LNCs are a promising delivery system for enhancing the solubility, stability, and bioavailability of RSP with the potential to reinforce its therapeutic efficacy in schizophrenia treatment.

**Keywords:** Risperidone, Lipid Nanocapsules, Schizophrenia, Solubility, Cytotoxicity.

**formulation and evaluation of buccal films for a solubility enhanced anti-hypertensive agent**

Kunika Chopkar, Divya Malode, Dinesh Biyani, Rashmi Trivedi
Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Maharashtra 441002
kunikachopkar@gmail.com

Felodipine, a BCS Class II antihypertensive agent, suffers from poor aqueous solubility and extensive first-pass metabolism, restricting its bioavailability. This study aimed to develop a buccal film of Felodipine, incorporating solid dispersion to enhance solubility and bypass hepatic metabolism. Solid dispersions were prepared by solvent evaporation with hydrophilic polymer HPMC E15 to achieve molecular-level dispersion. The optimized dispersion was incorporated into buccal films via solvent casting, ensuring uniform drug distribution, desirable mechanical properties, and rapid disintegration. Characterization confirmed drug-polymer interaction and amorphous conversion. FTIR spectra revealed absence of chemical incompatibility, DSC thermograms showed disappearance of the sharp melting peak of the drug, and XRD patterns indicated reduced crystallinity. Physicochemical evaluations, including thickness, folding endurance, tensile strength, surface pH, swelling index, drug content uniformity, and disintegration, confirmed suitability for buccal delivery. The optimized film exhibited a disintegration time of 28 seconds and released 95% of Felodipine within 10 minutes. Ex vivo studies showed cumulative drug permeation of 1204.8 µg/cm³ in 10 minutes, demonstrating effective transmucosal delivery. This innovative formulation offers a Promising strategy to overcome Felodipine's Solubility and bioavailability challenges, providing a scalable and patient-friendly strategy, offering improved therapeutic efficacy in antihypertensive therapy.

**Keywords:** Felodipine, Buccal films, Solid dispersion, Solubility enhancement, Bioavailability enhancement, Antihypertensive therapy.

**TOPICAL DELIVERY OF GRISEOFULVIN USING NATURAL BIOENHANCERS: FORMULATION, CHARACTERIZATION AND IN-VITRO EVALUATION**

Amol Ashok Shirsath, Aparna V. Bhalerao, Saurabh Suraj Jadhav, Pragati Anil Nawale
School of Pharmaceutical Sciences, JSPM University, Pune, India 412 207
aas.sphs@jspmuni.ac.in

The effectiveness of topical antifungal therapy is often constrained by poor skin penetration, particularly in thick keratinized tissues, the emergence of resistance, and incomplete eradication of infection. Bioenhancers of natural origin, though pharmacologically inert when administered alone, have demonstrated the ability to enhance drug permeability and bioavailability. While their role in improving oral drug delivery has been extensively studied, their potential applications in topical drug delivery remain underexplored. The study aims to develop a topical formulation of griseofulvin a antifungal agent for the treatment of dermatophytic infections of the skin, hair, and nails, with the herbal bioenhancer piperine to enhance skin penetration and therapeutic efficacy. Carbopol 934-based gels of griseofulvin with and without different amounts of piperine were prepared and evaluated for pH, viscosity, spreadability, drug content and ex-vivo studies. Before formulation, drug–excipient compatibility was confirmed by FTIR and UV analysis. The formulations showed translucent, non-gritty appearance, pH(around 6.1–6.5), viscosity(9500-11200cp), good spreadability and drug content (96.8-97.2%). Ex-vivo release study showed that the gel containing 1.0% piperine released about 82% of drug over 8 hours, compared to about 61% for the gel without piperine. In-vitro antifungal activity confirmed the enhancing effect of griseofulvin with piperine, yielding larger zones of inhibition against Trichophyton ruburum species. Stability studies indicated the formulation remained stable under different conditions. The incorporation of piperine markedly improved the topical therapeutic performance of Griseofulvin, highlighting the strategic potential of natural bioenhancers in optimizing antifungal formulations and extending their applicability to the enhancement of other topical antibacterial agents.

**Keywords**: Topical antifungal therapy, Griseofulvin, Piperine, Bioenhancer

**FORMULATION DEVELOPMENT AND ASSESSMENT OF POLYHERBAL CREAM FOR THE MANAGEMENT OF FUNGAL SKIN INFECTIONS**

Shraddha Bagmare, Harshali Waze, Dinesh Biyani, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India- 441002
shraddhabagmare06@gmail.com

Fungal skin infections are among the most common dermatological ailments worldwide, and the overuse of conventional antifungal drugs such as ketoconazole, fluconazole, and amphotericin B has contributed to resistance and limited efficacy. Polyherbal formulations, which combine multiple plant extracts known for antifungal properties, offer a promising natural and potentially synergistic alternative. This study aimed to formulate a novel polyherbal antifungal cream utilizing the medicinal properties of Azadirachta indica (neem), honey and lavender oil and to evaluate its physicochemical characteristics, stability, safety, and antifungal efficacy against common skin pathogens. Ethanolic extracts of Azadirachta indica (neem) leaves were obtained using Soxhlet extraction and analysed using UV-Visible spectrophotometry, FTIR, phytochemical screening, and thin-layer chromatography, confirming the presence of biologically active compounds such as flavonoids, alkaloids, terpenoids, and tannins. A series of cream formulation were prepared using oil-in-water emulsions and optimized using a 32 full factorial design to evaluate the effects of cetyl alcohol, stearic acid, and Tween 80 on key characteristics, including viscosity and spreadability. The optimized cream underwent rigorous evaluation for pH, homogeneity, washability, irritancy, drug content, and in vitro release using a Franz diffusion cell. Its antifungal activity was assessed against Candida albicans via the agar well diffusion method, demonstrating substantial zones of inhibition comparable to a standard clotrimazole cream. The study concludes that the polyherbal cream offers a stable, non-irritant, and effective natural alternative for managing fungal infections, with enhanced patient compliance and therapeutic potential. This formulation demonstrates the potential of integrating traditional herbal medicine into modern dermatological applications.

**Keywords:** Polyherbal, Azadirachta indica (neem), Antifungal cream, Clotrimazole.

**DESIGN AND OPTIMIZATION OF PLGA-BASED PACLITAXEL NANOPARTICLE DRY POWDER INHALER FOR TARGETED PULMONARY DELIVERY IN LUNG CANCER**

Prachita Duara, Madhurjya Pawan Deka and Trideep Saikia
School of Pharmaceutical Sciences, Girijananda Chowdhury University, Hatkhowapara, Azara, Guwahati, Assam, India-781017.
prachitaduara@gmail.com

An efficient and selective delivery system for chemotherapy drugs in lung cancer is still a significant hurdle to overcome. An approach that looks particularly promising is the use of dry powder inhaler (DPI) formulations which allow for the localized delivery of anticancer drugs to the lungs. In this study, Paclitaxel DPI was formulated using PLGA-based paclitaxel nanoparticles, which were prepared via the emulsification–solvent evaporation method. The formulation was optimized with Design Expert® software, which evaluated the effect of core formulation and process parameters. The optimized nanoparticles showed a mean particle size of 178.4 ± 6.2 nm and a drug entrapment efficiency of 91.8 ± 2.1%. The DPI powders had good flow properties and dosing uniformity, and scanning electron microscopy showed that the particles had a smooth and spherical morphology. Drug release in vitro showed a sustained diffusion-controlled release pattern, with about 30% released at 24 h. The aerodynamic evaluation showed effective lung deposition, with a fine particle fraction (FPF) of 52.3 ± 3.1% and particles having an aerodynamic diameter less than 5 µm. In summary, the optimized PLGA-based Paclitaxel DPI offers advanced, tailored, pulmonary drug formulation technology.

**Keywords:** Paclitaxel; PLGA nanoparticles; Dry powder inhaler (DPI); Lung cancer therapy; Pulmonary drug delivery

**DEVELOPMENT AND CHARACTERIZATION OF BUCCAL FILMS OF CEFPODOXIME PROXETIL FOR ENHANCED DRUG DELIVERY**

ISBN: 978-81-980623-8-3

Nimmi Thankam Biju, Ajitha K Cherian, SR Daisy P A
Department of Pharmaceutics, St. Joseph's College of Pharmacy, Cherthala, Kerala, India- 688524.
nimmithankambiju@gmail.com

Drug delivery through the buccal mucosa provides an advantageous route as it bypasses first-pass metabolism and enhances therapeutic efficacy. Buccal films, being flexible and comfortable, offer better patient compliance compared to conventional tablets. In this study, buccal films of Cefpodoxime proxetil, an orally active ester prodrug that undergoes intestinal absorption and de-esterification to release a third-generation cephalosporin, were developed. The drug is widely indicated for respiratory, urinary, skin, and soft tissue infections caused by both gram-positive and gram-negative bacteria. Chitosan, Gelatin, and Pectin were employed as the primary polymeric substrates for film formulation. Preliminary pre-formulation studies, including infrared spectroscopy and solubility profiling were conducted. Seven formulations were prepared using the solvent casting method and evaluated for physicochemical parameters such as appearance, surface texture, weight variation, thickness, swelling index, folding endurance, surface pH, moisture loss, and moisture absorption. Mechanical properties including tensile strength and elongation at break were also assessed. In-vitro drug release studies were performed using USP dissolution apparatus type II in 400 mL phosphate buffer (pH 6.8) at 50 rpm and 37 ± 0.5 °C, with absorbance measured at 235 nm. Among the formulations, F6 exhibited the highest cumulative drug release of 98.91% within 390 minutes, and was selected as the optimized formulation. The optimized buccal film contained Chitosan, Hydroxypropyl Methylcellulose, Polyvinylpyrrolidone, and Propylene Glycol as a plasticizer. Further characterization including antimicrobial assay (agar diffusion), stability studies, and release kinetics confirmed the suitability of the optimized film, with all results falling within acceptable limits.

**Keywords:** Cefpodoxime proxetil, Chitosan, solvent casting method, in-vitro drug release, anti-microbial study.

## FORMULATION AND EVALUATION OF PUNICALAGIN ANTICANCER NASAL SPRAY

Shaikh Asmat, Furquan Khan
Department of Pharmaceutical Quality Assurance, Y.B. Chavan College of Pharmacy,
Ch. Sambhajinagar (Aurangabad), Maharashtra, India-431001
shaikhasmat55@gmail.com

A Nasal spray formulation of Punicalagin, a polyphenolic compound from pomegranate (Punica granatum) was formulated and assessed. Since punicalagin has poor oral bioavailability due to its extensive first pass metabolism that leads to its conversion into urolithins its nasal delivery system was developed. This delivery system avoids hepatic first-pass metabolism and enhance systemic drug absorption. This allows the compound to directly target the upper respiratory tract, where it can exert its potent anti-inflammatory, antioxidant, antimicrobial and anticancer effects. The pure Punicalagin API was extracted and isolated successfully from Pomegranate peel raw powder. The Punicalagin was characterized for color, odor, melting point and potency by TLC and HPLC analysis. QbD methodology was employed to examine the extraction efficiency by using different solvents. A 32 experimental design was employed to get the best ratio of solvents and time for extraction. The results obtained after experimentation were subjected to statistical analysis, i.e., ANOVA. The statistical analysis revealed that the model for the design of the experiment was significant. The extraction efficiency study by QbD revealed that batch that has 100% water & 24 hrs extraction time was required to achieve maximum yield. A nasal spray formulation of Punicalagin was developed using Poloxamer, Sodium chloride, and Phenylethyl alcohol. Stability studies were performed & it was found that the prepared formulation is stable without any drug degradation. All the evaluation tests passed without observing any suspended particles. The developed formulation was further characterized for pH, viscosity, spray pattern, Plume geometry, permeability and assay.

**Keywords:** Punicalagin, Nasal spray, Quality by Design, stability studies, factorial design.

## 3D PRINTED POLYMERIC MICRONEEDLE ARRAYS: INDIRECT FABRICATION, STRUCTURAL EVALUATION, AND TRANSDERMAL DELIVERY OF AN ANTIPSYCHOTIC DRUG

Geethu M, Srinivas Mutalik
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal, Karnataka, India-576 104
geethum13@gmail.com

Traditional drug delivery approaches such as oral tablets, nasal sprays, topical creams, and intravenous injections often encounter challenges, including poor patient compliance, variable bioavailability, and delayed therapeutic action. Transdermal patches have been explored as alternatives; however, their effectiveness is limited by poor diffusion through the stratum corneum. Microneedle Arrays (MNAs) present a transformative solution, enabling painless and efficient drug permeation across the skin barrier. This study focuses on the indirect fabrication of polymeric MNAs via 3D printing, designed specifically for the transdermal delivery of an antipsychotic drug. Master molds were fabricated using CAD-assisted 3D printing, ensuring precise control over microneedle length, base diameter, tip sharpness, and spacing. Polymeric casting into these molds resulted in robust microneedle patches with consistent architecture. Morphological analysis confirmed uniform needle geometry and sharpness critical for skin penetration, while mechanical testing demonstrated adequate fracture resistance and insertion strength without compromising patient comfort. The integration of an antipsychotic drug within these microneedles establishes a novel delivery platform with the potential to bypass first-pass metabolism, enhance bioavailability, and improve therapeutic efficiency in psychiatric disorder management. By combining 3D printing-enabled design precision with polymeric flexibility, this work underscores the significance of fabrication methodology and structural optimization in advancing microneedle technology for drug delivery. The approach demonstrates the promise of microneedle-mediated transdermal systems as a next-generation alternative to conventional formulations.

## FORMULATION, EVALUATION AND OPTIMIZATION OF KOJIC ACID DIPALMITATE HERBAL BASED NANOEMULGEL FOR THE TREATMENT OF HYPERPIGMENTATION

Archana S. Patil, Arpana Patil
Department of Pharmaceutics, KLE College of Pharmacy, KLE Academy of Higher Education and Research Belagavi, Karnataka, 590010, India

Hyperpigmentation is a common dermatological disorder caused by excess melanin synthesis, often treated with hydroquinone, which has significant side effects. Kojic Acid Dipalmitate (KAD), a stable derivative of kojic acid, offers a safer alternative but suffers from limited solubility and skin penetration. To overcome these challenges, a novel KAD nanoemulgel incorporated into a flaxseed-based herbal gel was formulated, optimized, and evaluated. The nanoemulsion was prepared using clove oil (20% w/v), Smix (Tween 80: Span 80, 70% w/v), and water (10% w/v), followed by incorporation into a gel base containing flaxseed extract (4% w/v) and Carbopol 940 (0.12% w/v). Optimization was achieved through pseudo-ternary phase diagrams and Box-Behnken statistical design. The optimized nanoemulsion exhibited nanosized droplets (10–80 nm), high drug content (up to 98.5%), low PDI, and excellent stability under refrigerated and ambient storage conditions. TEM analysis confirmed spherical morphology. The developed nanoemulgel demonstrated sustained in vitro drug release (82% in 24 h), efficient ex vivo permeation (79% in 24 h), and strong inhibition of melanin synthesis and tyrosinase activity in α-MSH-induced B16F10 melanoma cells, in a dose-dependent manner. Skin irritancy studies on Wistar rats confirmed the non-irritant nature of the formulation. The incorporation of flaxseed, with its antioxidant and anti-inflammatory properties, further enhanced biocompatibility and therapeutic efficacy. Overall, the KAD flaxseed-based nanoemulgel provides a safe, stable, and effective topical alternative to hydroquinone for the management of hyperpigmentation.

**PREPARATION, CHARACTERIZATION AND EVALUATION OF DRUG-DRUG COCRYSTAL TO ENHANCE THEIR UTILITY**

Dhiraj B. Dabhade, Dinesh M. Biyani, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra-441002

Poor aqueous solubility remains a major challenge in pharmaceutical dosage form development, particularly for Biopharmaceutics Classification System (BCS) Class II drugs. While amorphous solids offer improved solubility, their stability limitations necessitate alternative strategies. Cocrystallization presents a promising approach by modifying physicochemical properties without altering the molecular structure or pharmacological activity. The present work focuses on developing and characterizing drug–drug cocrystals of Glibenclamide (antidiabetic) and Rosuvastatin calcium (antidyslipidemic) to enhance solubility and dissolution performance, with a potential advantage for combination therapy in diabetes-associated cardiovascular complications. Cocrystals were prepared using the solvent evaporation method at various molar ratios. Among the formulations, the 2:1 molar ratio (F4) exhibited superior solubility and dissolution compared to pure drugs. Structural characterization by PXRD and DSC confirmed the formation of a distinct crystalline phase, FTIR demonstrated strong intermolecular hydrogen bonding, SEM revealed significant morphological modifications, and zeta potential analysis indicated good dispersion stability. The findings establish that Glibenclamide–Rosuvastatin calcium cocrystals significantly improve solubility and dissolution, supporting drug–drug crystallization as a novel and effective formulation strategy for poorly water-soluble therapeutic agents.

**Keywords:** Glibenclamide, Rosuvastatin, Drug-Drug cocrystal, Solvent evaporation, Combination therapy

**SMART MICRONEEDLE PATCH: AI DRIVEN BIOSENSING, BRIDGING PERSONAL CARE, SUSTAINABILITY AND ACCESSIBILITY**

Ekta Kumari Satish Singh, Pravin Kumar Sharma, Sumeet Dwivedi, G. N. Darwhekar
Acropolis Institute of Pharmaceutical Education and Research, Indore (M.P), India - 453771
ektakumarisingh.bph24@acropolis.edu.in

The evolution of medical devices is moving from simple monitoring tools to smart, patient friendly and sustainable therapeutic system. In this review we are focusing on developing smart microneedle patch with integrating biosensor, which uses AI to deliver drug when it is required with the aim of advancing personalized pharmacotherapy. The device combines graphene-based electrochemical biosensors for continuous monitoring of glucose, lactate, and electrolytes with AI algorithms that predict fluctuations and initiate on-demand drug release via biocompatible microneedle arrays. The device uses a mobile app that gives real-time feedback and connects patients with doctors through telemedicine. It offers smart features like predicting changes in health using biosensors, reminding patients to take medicines, and tracking their treatment. The patch is eco-friendly because it uses biodegradable materials and can be made with 3D printing, which also makes it affordable and customizable for different patients. The Patch focuses on four main domains like predictive intelligence, patient-centric usability, eco-conscious materials, and feasibility. We can conclude that, this device demonstrates a comprehensive framework for next-generation medical technologies. It holds the potential to revolutionize chronic disease management, reduce environmental burden, and set a new benchmark for futuristic, sustainable, and translational drug delivery systems.

**FORMULATION AND EVALUATION OF ANTISUNBURN PREPARATION WITH NANOPARTICLES FROM CYNODON DACTYLON (L.) PERS. LEAF EXTRACT**

SEJAL SUNIL DARANDALE
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist- Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
sejaldarandale01@gmail.com

Nanoparticles can be formed using Cynodon dactylon (Bermuda grass) by preparing an aqueous leaf extract, then adding a solution of metal ions (like silver nitrate) to it to initiate the reduction and stabilization of the ions into nanoparticles. The process relies on biologically active compounds such as polyphenols found in the plant extract, which act as reducing and capping agents, resulting in the formation of metal-based nanoparticles (e.g., silver or copper nanoparticles) that have shown potential for applications like antisunburn preparations due to their antioxidant and antibacterial properties. Evaluation parameters for Cynodon dactylon nanoparticles antisunburn preparations include nanoparticles characteristics (size, shape, stability, and zeta potential), formulation properties (pH, viscosity, spreadability, and washability), and in vitro and in vivo performance, such as antioxidant activity, photoprotective effects against UV radiation, and skin irritation studies to ensure safety and efficacy. The introduction of silver nanoparticles loaded with Cynodon dactylon shows potential as an efficient bioavailability enhancer for antisunburn preparations thus potentially lowering medication doses and adverse effects.

**TRIPLE ANTIOXIDANT NANOPARTICLE CREAM: POMOGRANATE EXTRACT, VITAMIN E AND RESVERATROL-LOADED HYALURONIC ACID FOR ANTIWRINKLES AND UV PROTECTION**

M Ruchita, M Padmasree, B A Vishwanath
Department of Pharmaceutics, Aditya Bangalore Institute of Pharmacy Education and Research, Yelahanka Bangalore, Karnataka, India - 560064
mruchita9449@gmail.com

Oxidative stress is the main cause of skin aging because it speeds up the breakdown of collagen, decreases its elasticity, and promotes the development of wrinkles. Natural antioxidants are known to be effective agents in reducing oxidative damage by neutralizing reactive oxygen species (ROS) and supporting dermal repair. Pomegranate extract, vitamin E, and hyaluronic acid exhibit skin-restorative properties that improve hydration, stimulate collagen production, and defend against oxidative stress, rendering them suitable for anti-aging formulations. The purpose of this study was to develop and evaluate a cream based on triple-antioxidant nanocarriers using a Design of Experiments (DoE) approach for process optimization. Nanoparticles were prepared by solvent evaporation method by using chitosan, resveratrol, methanol, polyvinyl alcohol, and sodium lauryl sulfate, followed by emulsification, centrifugation, and washing. Before incorporation into a cream base, important process parameters such as stirring speed were optimized to achieve the desired particle size distribution. The developed formulation was characterized for entrapment efficiency, drug loading, pH, and in-vitro release kinetics. Results indicated 90.81% entrapment efficiency, 90.88% drug loading, 96% cumulative drug release, pH of 6.0, and viscosity of 26,300 cP, confirming formulation stability and dermal compatibility. The present research work suggests that triple-antioxidant nanocarrier-based creams may be a promising approach for targeted anti-aging therapy and enhanced skin hydration.

**Keywords:** Nanoparticles, Antioxidants, Anti-aging, Dermal delivery, Nanocarriers.

**EVALUATING THE EFFICACY OF COPPER SULPHATE TOOTHPASTE IN REDUCING DENTAL PLAQUE**

Lekhana N V, A. Geethalakshmi, Akash Gowda P
Department of Pharmaceutics, Harsha College of Pharmacy, Nelamangala, Bangalore, India - 562123
lekhananvishwanath02@gmail.com

As a cosmetic product, toothpaste is becoming more and more popular. Dental plaque is a widely recognized factor in the initiation and progression of a variety of oral diseases. Dental plaque is the diverse microbial community found on the tooth surface embedded in a matrix of polymers of bacterial and salivary origin; if it is permitted to build up,

ISBN: 978-81-980623-8-3

it will solidify into tartar. Tartar is a deposit of tooth plaque. The most frequent cause of dental plaque is Streptococcus mutans. This study involves the formulation, comparative physicochemical analysis and antibacterial efficacy of toothpaste containing copper sulphate. The primary action of this toothpaste is antiplaque activity. The formulation contains copper sulphate as antimicrobial agent along with calcium carbonate as abrasive, glycerol as humectant, sodium lauryl sulphate as foaming agent, carboxy methyl cellulose as thickening agent, propyl paraben as preservative by trituration method. Four formulations were formulated by varying the copper sulphate concentration. All the four formulations (F1, F2, F3 and F4) were evaluated for various parameters like colour, appearance, pH (8.37-8.460 spreadability (3.266cm2 - 4.066cm2), viscosity(52000-56000cps), abrasiveness foaming power (5.1-5.5) and stability studies. Toothpaste containing Copper sulphate was tested for antimicrobial activity against Streptococcus mutans with different concentrations of copper sulphate. Formulation three (F3) was stable and found to be most active against the bacteria as seen by zone of inhibition(2.9cm).

**Keywords:** Tooth Paste, Antiplaque, Copper sulphate, Streptococcus mutans

## DEVELOPMENT AND OPTIMIZATION OF GASTRORETENTIVE FLOATING MICROSPONGES FOR TARGET DRUG DELIVERY SYSTEM

Mayuri Randive, Megha Kapse, Dinesh Biyani, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur
mayuri24052001@gmail.com

Microsponges have emerged as a promising drug delivery system to enhance bioavailability, prolong release, and minimize adverse effects. The present study focused on the development and optimization of gastroretentive floating microsponges for site-specific absorption in the upper gastrointestinal tract, addressing limitations such as poor gastric stability and rapid plasma clearance. Microsponges were prepared by the quasi-emulsion solvent diffusion method using Eudragit as the polymer and polyvinyl alcohol (PVA) as the stabilizer. Optimization was carried out through a Box–Behnken design, using Eudragit concentration, PVA concentration, and stirring speed as independent variables. Morphological analysis revealed spherical, porous microsponges. DSC confirmed the amorphous state of the active compound, while FTIR indicated no interaction between the drug and polymer. The optimized formulation exhibited a particle size of 246.5 ± nm, polydispersity index of 0.313, and zeta potential of -59 mV. Entrapment efficiency was 88.04%, with 92.21% drug release and 84.68% buoyancy. The optimized microsponges were encapsulated into hard gelatin capsules and evaluated for micromeritic properties, disintegration time, and in vitro release. Overall, the developed microsponge based delivery system demonstrated effective gastroretention and controlled release, highlighting its potential for improved therapeutic performance.

**Keywords:** Microsponges, Floating, Entrapment efficiency, Buoyancy, Drug release.

## FORMULATION AND DEVELOPMENT OF BUCCOADHESIVE DRUG DELIVERY SYSTEM FOR EFFECTIVE MANAGEMENT OF HYPERTENSION

Tanu Hatel, Manasi Thakre, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee
tanuhatel102003@gmail.com

A full factorial design approach was employed to develop Bucco adhesive tablets for enhanced solubility and controlled drug release of a poorly water-soluble therapeutic agent. The formulation factors were systematically varied to study their influence on key responses, including swelling behavior and drug release characteristics. Preformulation studies using spectroscopic analysis confirmed the compatibility between the drug and excipients, ensuring stability throughout the development process. The powder blends were evaluated for essential precompression parameters such as bulk density, tapped density, and angle of repose to ensure good flow properties. The prepared tablets were then characterized for hardness, friability, swelling index, bioadhesive strength, and invitro drug dissolution to assess their performance and reliability. The findings revealed that the selected formulation variables had a significant impact on both swelling behavior and drug release profiles. The maximum swelling index bioadhesive strength and in vitro drug release were found to be 0.262 gm, 10.54 gm, and 93.08%, respectively. Among all the formulation batches, the F9 batch gave optimum results. Overall, the study demonstrated that systematic formulation design can successfully improve the solubility and controlled release of poorly water soluble drugs, offering a promising approach for enhanced therapeutic efficacy and patient compliance.

**Keywords**: Buccoadhesive, Factorial design, Solubility enhancement, Controlled drug release.

## FORMULATION AND EVALUATION OF SILVER NANOPARTICLES OF BAUHINIA RACEMOSA LAM

Bhakti S Kale, R. B. Pandhare, V. K. Deshmukh
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist-Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
kalebhakti307@gmail.com

The present study focuses on the green synthesis, characterization and biological evaluation of silver nanoparticles (AgNPs) synthesized using the ethanolic extract of Bauhinia racemosa Lam leaves. Preliminary phytochemical screening confirmed the presence of alkaloids, flavonoids, glycosides, steroids, phenols, saponins and tannins, which acted as natural reducing and capping agents. Visual color change and UV–Visible spectroscopy (λmax 418–433 nm) confirmed successful nanoparticles formation. Characterization using dynamic light scattering (DLS), zeta potential analysis, SEM and XRD validated the formation of stable, crystalline and uniformly sized AgNPs (38.9–63.8 nm) with good colloidal stability. Drug content across batches ranged from 88.93% to 96.04%, and in-vitro drug release demonstrated sustained release behavior over 8 hours, with batch B8 exhibiting the highest cumulative release (94.2%). Cytotoxicity studies using the MTT assay on MCF-7 cell lines showed a concentration-dependent response, with an estimated $IC_{50}$ of ~95 µg/mL for the sample, compared to 6 µg/mL for 5-fluorouracil. Antimicrobial evaluation revealed significant antibacterial activity against E. coli, S. aureus, and B. subtilis and moderate antifungal activity against Candida albicans and Aspergillus niger. These results affirm the potential of Bauhinia racemosa-mediated AgNPs as promising candidates for biomedical applications, particularly in antimicrobial and anticancer therapy.

**Keywords:** Bauhinia racemosa Lam, Green synthesis, Silver nanoparticles, Cytotoxicity, Antimicrobial activity.

**PC-463**

## FORMULATION, DEVELOPMENT AND EVALUATION OF A NANOGEL BASED TOPICAL SYSTEM FOR EFFECTIVE ECZEMA THERAPY

Sakshi R. Nerkar, Chetana J. Shelote, Nishant B. Awandekar, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee
sakshinerkar02@gmail.com

Eczema is a chronic skin disorder characterized by persistent inflammation and has reached near epidemic proportions. It is often the earliest manifestation of atopy and is challenging to manage due to its early onset in childhood. Clinical features include dryness, lichenification, itching, and erythematous skin. Current therapeutic strategies for eczema fall into three categories: basic care, topical therapy, and systemic therapy. However, these treatments have significant limitations, necessitating the development of novel approaches. Some drugs when administered orally are associated with several adverse effects such as infections, nausea, vomiting, loss of appetite, liver dysfunction, and leukopenia. Less common but serious side effects include hepatitis (liver inflammation), pancreatitis (inflammation of the pancreas causing pain), and allergic reactions manifesting as flu like symptoms or rash. To overcome these drawbacks altering the route of administration is a promising strategy. The present investigation aimed to develop a topical formulation in the form of a nanogel leveraging its nanoscale size for enhanced absorption and reduced systemic side effects. Niosomes were prepared using the coacervation phase separation method and optimized through a $3^2$ full factorial design, with entrapment efficiency and drug release as response parameters. Among the batches, N5 was identified as the

ISBN: 978-81-980623-8-3

optimized formulation demonstrating an entrapment efficiency of 83.76 ± 1.01% and a maximum drug release of 69.73 ± 1.17%. The optimized niosomal dispersion was then incorporated into a gel and evaluated for drug release, viscosity, spreadability, pH, and skin irritation potential.

**Keywords:** Eczema, Topical drug delivery, Niosomes, Nanogel, Entrapment efficiency, Drug release.

## DEVELOPMENT AND CHARACTERIZATION OF BERGENIN NANOPARTICLES FOR THERAPEUTIC MANAGEMENT OF ADJUVANT-INDUCED ARTHRITIS

AKHILESH, PALLAVI AHIRRAO
Chandigarh College of Pharmacy, Landran, Mohali, Punjab, India, 140307

In this research study, Bergenin loaded nanoparticles were prepared to improve the oral bioavailability of Bergenin. Bergenin is a colorless, crystalline, natural phenolic C- glycoside found in the plants of Bergenia species. It falls under Class IV of Biopharmaceutics Classification System with poor solubility and low intestinal permeability which limited its oral bioavailability. To improve its oral bioavailability it needed to be incorporated in a suitable polymeric nanoformulation. The Pre-formulation study of Bergenin included FTIR, melting point, calibration plot, pH determination, partition coefficient and XRD analysis. Bergenin nanoparticles were prepared using an emulsion solvent evaporation method. The prepared nanoparticles were evaluated for their particle size (246.9nm), PDI (0.356), drug entrapment (91%), drug loading (16.56%), Drug percentage (97%), drug release from polymeric nanoparticles (91%), SEM (spherical in shape), TEM, FT-IR, pXRD, DSC etc. The in-vitro and in-vivo (SD rats) study was performed to check the anti-arthritic activity of Bergenin nanoparticles against the standard, Indomethacin. Bergenin nanoparticles demonstrated significant anti-arthritic effect in diseased SD rats with no observed toxicity in animal model, suggesting its safety and efficacy. It is concluded that the method of preparation of Bergenin loaded PLGA nanoparticles was found to be simple and reproducible. The in-vitro and in-vivo studies further confirm the improved pharmacokinetic and pharmacodynamic profiles of Bergenin nanoformulation highlighting its enhanced anti-inflammatory /anti-arthritic activity.

**Keywords:** Bergenin, nanoformulation, antiarthritic activity, Pharmacokinetic and pharmacodynamics.

**PC-465**

## MULTIPLE-UNIT PELLET SYSTEMS (MUPS) : DEVELOPMENT OF STABILIZED PROLONGED RELEASE FORMULATIONS OF MIGLITOL FOR THE TREATMENT OF TYPE 2 DIABETES

Vatti Sumanth Reddy, Mandapati Ramesh Naidu, Padala Narayana Raju and Chimakurthy Jithendra.
M/s Therallen Pharma Private Limited, Plot No. 67, 1st floor, Chitiprolu Arcade, Jubilee Enclave, HITEC City, Madhapur.
sumanth.v@therallen.com

In this present investigation, Miglitol pellets were prepared using Wurster coating process using Fluid bed processor (FBP). The process involved in two steps such as drug loading and extended-release coating. The drug loading of Miglitol was coated on sugar spheres using HPMC E 5 as binder. The extended-release coating process was done using coating on drug loaded pellets using combination of Eudragit L 100 and S 100 at different ratio (22- 43 % of polymer coating). The pellets were compressed in to tablets (MUPS). Various formulation and process parameters were evaluated. The results of invitro dissolution showed the extended release of 8 hrs at lower polymer coating and the release was extended up to 15 hrs at higher polymer concentration. A combination of polymer such as 26 % of Eudragit RL 100 and 9 % of Eudragit RS 100 yields best initial rapid release such as 42 % during first hour and later 59 % was prolonged up to 13 hours. The release form coating of Eudragit RS 100 alone showed only 63 % in 12 hours. The release kinetics showed first order release with diffusion mechanism. Results accelerated stability study showed that the drug was stable up to 6 months at 40ºC at 75% RH. DSC of pure drug showed a sharp endothermic peak at 145.67 O C , similar endothermic peaks were observed win the prepared formation concludes no drug polymer interaction. FTIR study further confirms that no interaction of drug and excipients. Scanning electronic microscopy (SEM) study showed the spherical and smooth surface of the pellets. Therefore Multiple-Unit Pellet (MUPS) Systems can be successfully employed for the development of Miglitol prolonged release formulations.

**Keywords:** Miglitol, MUPS, Eudragit RL &RS 100, FBP, Stability

**PC-466**

## FORMULATION AND EVALUATION OF COMBINATION OF RESVERATROL AND CURCUMIN INTRANASAL NANOEMULSION FOR TREATMENT OF EPILEPSY

Manish Kukulwar, Radhika Gupta, Jayshree Taksande, Amol Tatode, Milind Umekar
Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur - 441002
manishkukulwar@gmail.com

The aim of this study was to develop a combination of resveratrol and curcumin nanoemulsion for intranasal administration in the treatment of epilepsy. The nanoemulsion was prepared using high-speed homogenization and probe sonication, with fractionated coconut oil as the oil phase, Cremophor and Pluronic 127 as the surfactant. The formulation was selected as optimized based on a particle size analysis, globule size determination and drug content were employed to optimized. The prepared combination of resveratrol and curcumin nanoemulsion was characterized for various parameters including particle morphology, particle size, polydispersity index (PDI), zeta potential, centrifugation, heating cooling cycle, drug content, pH, viscosity and in vitro drug diffusion. The results showed that the combination of resveratrol and curcumin nanoemulsion had a particle size of 181 nm, indicating its suitability for nasal drug delivery. The low PDI value of 0.368 indicated a narrow size distribution, and the pH of 6.5 was suitable for nasal administration. In conclusion, the prepared combination of resveratrol and curcumin nanoemulsion was found to be suitable for intranasal administration, offering the potential to enhance drug absorption and bioavailability. This formulation may have promising implications for the treatment of epilepsy and other related conditions.

**Keywords:** Resveratrol, Curcumin, Nanoemulsion, Epilepsy, Intranasal adminstration

**PC-467**

## BIOELECTRICAL PATCHES: A NOVEL APPROACH TO WOUND HEALING

Anurag Khade, Vinita Kale, Suankit Harane, Milind Umekar
Department of Regulatory Affairs. Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India – 441002
anuragkhade17@gmail.com

Bioelectrical patches represent an innovative and promising technology in modern wound healing, leveraging the body's natural electrical signals to accelerate tissue repair and regeneration. These patches deliver controlled electrical stimulation directly to the wound site, facilitating cellular activities such as migration, proliferation, and angiogenesis, which are crucial for efficient healing. Advances have led to the development of self-powered systems with piezoelectric or triboelectric materials, smart wearable patches equipped with sensors for real-time monitoring, and biodegradable designs that negate the need for manual removal. Clinical studies demonstrate significant benefits, including up to 30% faster healing, 85% complete wound closure, a 50% reduction in infection rates, and high patient satisfaction, with minimal adverse effects reported. Bioelectrical patches find applications in chronic wounds, surgical incisions, burns, sports, pediatric, geriatric, veterinary, and military medicine, highlighting their versatility across diverse clinical scenarios. Despite these advances, regulatory considerations remain a major factor influencing clinical adoption. The approval process requires rigorous demonstration of biocompatibility, safety, and efficacy, adherence to medical device standards, and reliable performance data. Emerging smart and biodegradable features present further regulatory challenges, including ensuring patch durability, sensor accuracy, and environmental safety upon degradation. Cost constraints and product standardization are also critical for widespread clinical acceptance. Ongoing collaboration among researchers, clinicians, and regulators will be essential for ensuring these innovations meet global regulatory standards and can be integrated into mainstream wound care.

**Keywords:** Bioelectrical patches, Wound healing, Electrical stimulation, Regulatory approval, Smart wearable technology.

**EXTRUSION SPHERONIZATION: A METHOD TO DEVELOP STABILIZED PROLONGED RELEASE SACUBITRIL FOR THE TREATMENT OF HYPERTENSION**

Ramireddy VijayaBhaskara Reddy, Mandapati Ramesh Naidu, Padala Narayana Raju, Chimakurthy Jithendra.
M/s Therallen Pharma Private Limited, Plot No. 67, 1st floor, Chitiprolu Arcade, Jubilee Enclave, HITEC City, Madhapur.
vijay.r@therallen.com

The present study arrived to develop prolonged release Sacubitril for the treatment of hypertension. This study investigate the fesability of extrusion spheronization method and its optimization of process for stabilized, robust formulation of Sacubitril. The study includes the use of HPMC K 4 M , K 15 , K 100 and Eudragit NE 30 D (18-40 % of polymer content) as release rate controlling agent. The method of preparation involved is the preparation of wet mass of Sacubitril with diluent and rate controlling polymers. The prepared wet mass was passed through extruder to form the long extrudes. The prepared extrudes were spheronized to form spherical pellets. The pellets were finally dried at 40-45 O C. Effect of various formulation variables such as the diluent and polymer proportion was studied. Effect of various process variables such as speed of extruder and rotation of spherodizer on pellet formation was studies. The prepared pellets were evaluated for various physico chemical properties. The dissolution study showed a drug release extended up to 12-16 hrs depends on the polymer proprtion and type of polymer. The release kinetics showed zero order release with diffusion mechanism. DSC of pure drug showed a sharp endothermic peak at 156 O C , similar endothermic peaks were observed win the prepared formation concludes no drug polymer interaction. FTIR study further confirms that no interaction of drug and excipients. Scanning electronic microscopy (SEM) study showed the rough surface of the pellets. Therefore, extrusion spheronization method can be successfully employed for the development of Sacubitril prolonged release formulations.

**Keywords:** Sacubitril, pellets, HPMC, Eudragit NE 30 D, extrusion spheronization

**PC-469**

**FORMULATION DEVELOPMENT AND EVALUATION OF MICROWAVE ASSISTED GRAFTED CASHEW GUM AS SUSTAINED RELEASE MATRIX**

Sarita Garg
Vaish Institute of Pharmaceutical Education & Research, Rohtak, Haryana, India- 124001.
saritagarg6@gmail.com

Recent advancements in pharmaceutical technology emphasize the design of sustained release systems to enhance therapeutic efficacy. Polymers, particularly graft copolymers, play a pivotal role in such formulations. Microwave-assisted grafting offers an efficient and rapid method for preparing graft copolymers without the need for initiators. In this study, cashew gum, a natural polysaccharide, was grafted with acrylamide to develop sustained release matrix tablets of dapagliflozin a selective SGLT-2 inhibitor used in the management of type 2 diabetes mellitus. Dapagliflozin was characterized for its physicochemical properties including UV absorption, melting point, solubility, partition coefficient, and spectral analysis, confirming its purity and lipophilic nature. The graft copolymerization of cashew gum with acrylamide was successfully optimized for grafting efficiency and percentage conversion. Structural confirmation was performed using FTIR and SEM analysis. Matrix tablets were prepared by direct compression, and all pre- and post-compression parameters were within pharmacopoeial limits. In vitro dissolution studies in 0.1N HCl and phosphate buffer (pH 6.8) demonstrated that the optimized formulation (F4) exhibited sustained release behavior. Kinetic modeling revealed that drug release followed the Higuchi model, indicating a diffusion-controlled mechanism. Overall, microwave-assisted grafting of acrylamide onto cashew gum provides a simple and reproducible approach for the development of sustained release dapagliflozin tablets, offering improved glycemic control and better patient compliance in type 2 diabetes management.

**Keywords:** Graft copolymerization, Microwave-assisted method, Sustained release, Matrix tablets, Higuchi model.

**DEVELOPMENT AND EVALUATION OF MUCOADHESIVE BUCCAL PATCHES OF VENLAFAXINE HCL**

Rejaul Karim Ahmed and Kumara Swamy Samanthula
Faculty of Pharmaceutical Science, Assam down town University, Sankar Madhab Path, Gandhi Nagar, Panikhaiti, Guwahati, Assam, India, PIN – 781026.
rejaul70025@gmail.com

The present research work aimed to prepare and evaluate mucoadhesive buccal patches of Venlafaxine HCl. The buccal patches were prepared using combinations of HPMC E15 ethyl cellulose and PVP in different ratios, employing a solvent casting technique. FT-IR studies were performed to investigate the drug-excipient interaction. The prepared polymeric patches were characterized for various physiochemical parameters, including film thickness, weight uniformity, folding endurance, surface pH, swelling index, drug content, in-vitro release. The physiochemical parameters of buccal patches were found satisfactory. However, swelling and folding endurance increased with increasing polymer concentrations. The weight of the patches ranged from 105.4±1.66 to 147.6±2.39 mg, while the thickness varied between 0.42±1.33 and 0.59±1.20 mm with standard deviation values. The surface pH of every formulation was within 0.5 units of neutral pH, ensuring compatibility with the buccal mucosa. The swelling index ranged from 55.25±2.59 % to 74.33±1.95% w/w, and the folding endurance was between 82 ± 0.33 and 108 ± 0.65, indicating good mechanical strength. In-vitro release study showed that buccal patches with HPMC E15, ethyl cellulose and PVP exhibited a higher release (99.69±1.23%) in F8 compared to other formulations and have been considered as an optimized formulation. The study successfully developed mucoadhesive buccal patches of Venlafaxine HCl with desirable physicochemical properties, enhanced drug release, and promising therapeutic potential, suggesting their suitability for effective buccal drug delivery.

**MRNA-LIPID NANOPARTICLE DRUG DELIVERY POSING CHALLENGES TO REGULATORY AGENCIES**

Sakshi S. Bhagat, Vinita Kale, Suankit Harane, Milind Umekar.
Department of Regulatory Affairs, Smt. Kishoritai Bhoyar College of Pharmacy Kamptee Nagpur, India- 441002
sakshibhagat5632@gmail.com

mRNA-lipid nanoparticle (LNP) drug delivery presents significant regulatory challenges due to the novel and complex nature of these formulations. LNPs serve as carriers that protect and deliver mRNA therapeutics across biological barriers to target cells, but their unique physicochemical properties and components complicate regulatory evaluation. Key challenges include defining the classification of LNP lipid components as either active substances or novel excipients, as regulatory agencies differ in their approaches. This inconsistency impacts requirements for manufacturing, characterization, toxicity testing, and documentation. Furthermore, regulatory bodies require thorough demonstration of product quality, batch consistency, and safety profiles amid variability in lipid composition and particle size. The rapid development cycles for mRNA vaccines, such as those for COVID-19 variants, pose additional challenges in adapting existing regulatory frameworks designed for traditional biologics. There is a pressing need for harmonized guidelines on chemistry, manufacturing, and controls (CMC), with an emphasis on early engagement between developers and regulators to streamline approval pathways. Regulatory strategies must integrate risk-based approaches addressing the complexity of LNP formulations, accompanied by rigorous analytical characterization of critical quality attributes. Special regulatory pathways may also facilitate expedited review for mRNA-LNP therapies. Overall, overcoming these regulatory hurdles is essential for advancing the clinical translation and commercialization of mRNA-LNP therapeutics while ensuring patient safety and product efficacy.

Phyllanthus emblica L. (popular known as amla or Indian gooseberry) is an ephemeral tree belonging to the Euphorbiaceae family. Amla has an important role in the traditional medicine of India to reduce anxiety and burning sensation in skin and eyes, improve anemic condition, favor the health of the male reproductive system and reproduction, facilitate digestion, improve liver health, and also exert a tonic effect in the cardiovascular system . Phyllanthus emblica L. (also popularly known as amla) is a tree native to the India and Southeast Asia regions that produces fruits rich in bioactive compounds that could be explored as part of the increasing interest in naturally occurring compounds with biological activity. Thus, this review aims to highlight the nutritional aspects, rich phytochemistry and health-promoting effects of amla. Scientific evidence indicates that polyphenols are central components in fruits and other sections of the amla tree, as well as vitamin C. The rich composition of polyphenol and vitamin C imparts an important antioxidant activity along with important in vivo effects that include improved antioxidant status and activity of the endogenous antioxidant defense system. Other potential health benefits are the anti-hyperlipidemia and antidiabetic activities as well as the anticancer, anti-inflammatory, digestive tract and neurological protective activities. The promising results provided by the studies about amla bioactive compounds support their potential role in assisting the promotion of health and prevention of diseases.

**Keywords:** Polyphenols, Ascorbic acid, Antioxidant activity, Cardiovascular protection, Hyperlipidemia.

**DEVELOPMENT AND CHARACTERIZATION OF AQUASOMAL DRUG DELIVERY SYSTEM FOR TARGETED DELIVERY OF PACLITAXEL AGAINST COLORECTAL CANCER**

Vijay Sharma and Vijay Bhalla
Department of Pharmaceutics, SGT College of Pharmacy, SGT University, Gurugram – 122505 (Haryana) INDIA
vijay_ceutics07@yahoo.co.in

Oral drug delivery is the most convenient and preferred route of administration; however, drugs like paclitaxel face challenges due to poor solubility, instability, and extensive first-pass metabolism. To overcome these limitations, aquasomes—nano-sized self-assembling carriers with a ceramic core and sugar coating—were explored for enhancing paclitaxel's oral bioavailability and colorectal targeting. Calcium phosphate dihydrate cores were prepared using colloidal precipitation by sonication and subsequently coated with different polyhydroxyl oligomers (sucrose, maltose, lactose, trehalose, and cellobiose) to form aquasomes. Paclitaxel was loaded onto these carriers through adsorption followed by lyophilization. The formulations were characterized using SEM, FTIR, DSC, anthrone assay, and in-vitro release studies. Trehalose- (TA) and cellobiose- (CA) coated aquasomes exhibited the highest drug loading, with TA showing superior compatibility, spherical morphology, and enhanced release profile. Enteric coating of the optimized TA formulation (ETA) was performed to achieve colorectal targeting. ETA demonstrated controlled drug release for up to 480 minutes and retained stability of functional groups as confirmed by FTIR and DSC analyses. Cytotoxicity studies against HCT116 colorectal cancer cells revealed potent anticancer activity, while three-month stability tests confirmed the absence of physical or chemical degradation. In conclusion, trehalose-coated aquasomes (TA) proved to be the most effective formulation for paclitaxel delivery, combining favorable morphology, drug loading, stability, and dissolution characteristics. Enteric-coated TA (ETA) further improved therapeutic potential by enhancing colorectal targeting and sustaining release, thereby establishing aquasomes as a promising nanocarrier system for the oral delivery of poorly soluble anticancer drugs.

Glass ionomer cement (GIC) serves as a foundational material in restorative dentistry, recognized for its durable chemical adhesion, fluoride-releasing capability, and excellent biocompatibility. Despite these merits, conventional GICs face limitations related to brittleness and suboptimal mechanical strength, which restrict their broader clinical utility. Current advancements aim to convert GICs from passive restorative fillers to multifunctional bioactive platforms by refining composition, enhancing physical properties, and assessing clinical outcomes. Experimental approaches are centered on optimizing the powder-to-liquid ratio, controlling particle size distribution, and conducting standardized micro-hardness testing including the incorporation of remineralization agents and time-dependent strength evaluations. Antimicrobial efficacy studies focus on the diverse mechanisms of GIC action, therapeutic potential, and comparative analyses against other dental materials, all performed within the context of rigorous safety assessments. Research and product development are guided by key regulatory frameworks such as ISO 9917-1:2017 for dental cements, ICH Q3D for elemental impurities and FDA biocompatibility standards, ensuring safe and effective use. Notable innovations include the integration of remineralizing and antimicrobial additives, the use of GIC as a vehicle for localized drug delivery, and advances in chemical bonding and anti-cariogenic functions. Both laboratory and clinical performance analyses underscore the importance of correlating test data with long-term therapeutic outcomes, supporting regulatory clearance and expanded clinical adoption.

In the current research, a single liposome containing two antiepileptic drugs, Lamotrigine (LTG) and Levetiracetam (LEV), was formulated by the thin film dehydration-rehydration method. The objective behind the research was to develop a single delivery system for the delivery of two AEDs via the intranasal route for effective targeting of the brain, which may be effective in anti-epileptic poly-therapy. The formulation was evaluated for different parameters to confirm their effectiveness. The formulation was evaluated for its drug content, entrapment efficiency, particle size, and percentage drug release. The actual amount of drug present in the formulation of LTG and LEV was found to be 90.39 ± 0.46 % and 89.67 ± 0.28 % respectively. Entrapment efficiency for both the drugs LTG and LEV was found to be 87.40 ± 0.39 % and 85.91 ± 0.53 % respectively. The in-vitro drug release study of co-loaded liposomes was carried out using a diffusion cell apparatus for 12 hrs. The percentage of drug release at 12 hr for LTG and LEV was found to be 73.66 ± 3.24 and 76.82 ± 1.62, respectively. The formulated co-loaded liposomes were also evaluated for their particle size using Laser Particle Size Analyser was found to be 422 ± 2.65 nm. Therefore, it may conclude that the co-loaded liposomes of LTG and LEV have been successfully formulated, and can be an effective delivery system to deliver two AEDs by the Intranasal route.

Kusulu89@gmail.com

HIV drug formulation challenges include achieving sustained, high drug concentrations in viral reservoirs, overcoming poor drug bioavailability and degradation, ensuring patient adherence through palatable and easy-to-administer forms, addressing drug resistance, managing side effects like weight gain, improving targeted delivery, and increasing the global access to affordable and appropriate formulations, especially for children. Solid Lipid Nanoparticles (SLNs) enhance HIV drug delivery by improving the stability, bioavailability, and targeting of antiretroviral drugs, especially those that are poorly water-soluble. The lipid-based SLN structure protects drugs from proteolytic degradation, facilitates absorption via the lymphatic system, and enables controlled drug release. Specific HIV drugs like efavirenz and ritonavir have been successfully encapsulated in SLNs, showing increased peak plasma concentration and potential for targeting HIV reservoirs. In our study we have developed Solid lipid nanoparticles (SLN) of efavirenz and delaveridine by high pressure homogenization technique using optimised procedure by design of experiments and evaluated for particle size, polydispersity index (PDI), zeta potential and entrapment efficiency. The optimized SLN formulation was incorporated in thermo-sensitive in-situ gelling system. The efavirenz SLN based gel was evaluated for various parameters like gelation temperature, pH, viscosity, transmittance, mucoadhesive strength, Spreadability, in-vitro and ex-vivo release studies, and the in-vivo pharmacokinetic studies.

**Keywords:** Solid lipid Nanoparticles, High pressure homogenization, Design of Experiments , In-situ gel, Nose-to-brain, Brain targeting

## FORMULATION AND EVALUATION OF TRANDOLAPRIL EFFERVESCENT FLOATING TABLETS

Dr Gundu Nagamani, Dr M Thrinadharao, K Kameswara rao,Ch Sujani,T Anjali.
Department of Pharmaceutics, Adarsa college of Pharmacy, G.Kothapalli, Gokavaram Mandal, A.P-533285.
mani_1992@rediffmail.com

The present study involves preparation and evaluation of floating microspheres of an anti-hypertensive drug Trandolapril as a model drug for prolongation of gastric residence time using both gas forming agents like sodium bicarbonate The effervescent microspheres were prepared by Inotropic gelation technique using polymer sodium alginate along with Ethyl celluloseand HPMC K4M.The microsphere was evaluated for angle of repose, bulk density, tapped density, Carr's index, Hausner's ratio, percent yield and drug entrapment. The shape and surface morphology of prepared microsphere were characterized by scanning electron microscopy.In-vitro drug release studies were performed by using USP Dissolution test apparatus (type I) at 37 +_0.5o c and 50 rpm speed. To study release behaviour kinetic analysis were performed on the optimised formulation. The dissolution data were fitted to zero order, First order, Higuchi model and Peppas model. The prepared microspheres exhibited prolong release and remained buoyant for more than 12 hrs. The optimised formulation (F6) showed good percent yield, drug entrapment and drug release.

**Keywords:** Floating microspheres, Trandolapril, Effervescent systems, GRDDS.

## FORMULATION OF INTRANASAL SLN FOR ENHANCED BRAIN DELIVERY IN ALZHEIMER'S DISEASE

Swati N.Lade, Akanksha R. Ashtankar, Nishant B. Awandekar, Milind J. Umekar
Department of Pharamceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India-441002.
Swatilade09@gmail.com

The progressive neurodegenerative disease known as Alzheimer's disease (AD) is signified by behaviour abnormalities, cognitive decline, and memory loss. Because therapies cannot pass through the blood-brain barrier (BBB) efficiently, resulting in restricted brain bioavailability and systemic side effects, clinical outcomes are still inadequate even with the availability of numerous treatments. The goal of the current work was to create and assess a novel intranasal solid lipid nanoparticles (SLN) system for the brain-targeted administration of the antioxidant N-acetyl-L-cysteine (NAC) and the cholinesterase inhibitor rivastigmine hydrogen tartrate (RHT). The compatibility of RHT and NAC with particular lipids and surfactants was validated by preformulation studies. A Box-Behnken Design was used to optimize the RHT-NLCs for particle size and entrapment efficiency after they were created by hot melt emulsification and ultrasonication.The optimized formulation demonstrated an entrapment efficiency of 80.66% and a particle size of 154.7 nm. The effective encapsulation of the drug with stable physicochemical properties was validated by FTIR, DSC, and XRD studies. Studies performed in vitro and ex vivo showed improved nasal permeability and prolonged drug release. When compared to the free drug, RHT-SLNs significantly improved the cognition and memory of rats with $AlCl_3$-induced AD, according to behavioural studies. The results confirm that intranasal administration of RHT-loaded SLNs in combination with NAC is a successful method for improving brain delivery and Alzheimer's disease treatment effectiveness.

## DEVELOPMENT AND IN VITRO EVALUATION OF MEDICATED CANDY AS A NOVEL APPROACH FOR TB TREATMENT FOR PAEDIATRICS

A.Geethalakshmi, Pradeep Desai, Rohan Debnath, Rahul Prasad.
Department of Pharmaceutics, Harsha College of Pharmacy, Nelamangala, Bangalore, India - 562123
Pradeepdesai234@gmail.com

Tuberculosis (TB) therapy faces significant compliance challenges, particularly in children. This study focused on formulating and evaluating a child-friendly, palatable medicated hard candy of isoniazid to improve tolerability, compliance, and adherence. Eight formulations (F1–F8) of isoniazid hard candy were developed using the heat and congealing method with different polymer blends of Hydroxypropyl methylcellulose (HPMC-K100), Methyl cellulose, and Sodium Carboxymethylcellulose (Na-CMC). Pre-formulation studies confirmed the identity and purity of the drug, with a melting point of 170.3°C and maximum absorbance (λmax) of 263 nm. Fourier-transform infrared spectroscopy (FT-IR) verified "in-use" compatibility of isoniazid with selected excipients. The formulated candies were physically hard, red in color, and demonstrated acceptable tolerability and palatability. Mechanical property testing showed adequate hardness (15.6–18.3 kg/cm²) and low friability (0.12–0.35%). In-vitro release studies indicated that most formulations followed the Korsmeyer-Peppas release model, with high correlation coefficients ($R^2 \approx 0.9997$). Release exponent (n) values were greater than 1, suggesting a super case-II transport mechanism. Overall, the study demonstrated successful formulation of stable medicated isoniazid candies with desirable properties in terms of taste, appearance, strength, and drug release profile. Such a dosage form has potential to enhance paediatrics compliance in TB therapy. However, further studies are required to evaluate the in-vivo distribution, tolerability, and acceptance of isoniazid hard candy in children with TB.

**Keywords:** Isoniazid, Tuberculosis (TB), Medicated Candy, Paediatric, heat & congealing method

## ENHANCEMENT OF SOLUBILITY AND DISSOLUTION OF RESVERATROL BY SOLID DISPERSION TECHNIQUE

Ankita Dhopate and Atul Hemke
S. K. B. College of Pharmacy, Gada, Kamptee, Maharashtra, India – 441002.
ankitadhopte5@gmail.com

In the current research, the Resveratrol (RES) and chitosan-myristic acid complex were used for the formulation of solid dispersion (RES-SD). The objective behind the research was to examine solubility of RES. The RES-SD in stoichiometric ratio was prepared by dissolving both RES and chitosan-myristic acid complex in a 5ml of a mixture of ethanol:water (1:1), prepared by kneading technique. RES-SD4 formulation with ratio (1:6) was selected as optimized batch based on high drug content (98.02 % w/w). The aqueous solubility of RES-SD4 was found to be increased (71.344 µg/mL). RES-SD4 formulation was confirmed by solid state

ISBN: 978-81-980623-8-3

characterization using SEM, DSC, FTIR and PXRD. Dissolution pattern of pure RES, PM and RES-SD formulations in vitro in phosphate buffer pH 6.8 was studied, the pure RES exhibited only ~13.63 % release at the end of 2h testing period and prepared RES-SD formulations were found to show an enhanced rate and extent of dissolution with increasing water-soluble ratios of carrier. Formulation RES-SD4 demonstrate an enhanced dissolution release rate at around 90%, with similar testing period. The optimized formulation, RES-SD4 showed an excellent release rate in first one hour at about 67.12% and thereafter, this release rate continued to increase and reached to a maximum at about 98.02% (in pH 6.8) over the end of 2h testing period. Thus, RES-SD4 formulation showed enhanced solubility and dissolution of RES.

**Keywords:** Resveratrol, Chitosan, Myristic acid, Solid dispersion

**HYALUROSOMES OF CAFFEINE FOR DUAL PHARMACEUTICAL AND COSMECEUTICAL APPLICATION: A COMPREHENSIVE ANALYSIS USING BOX–BEHNKEN DESIGN**

Shalini Juglan1, Neha Sodiyal1, Shivanand Patil1, Peeush Singhal2, Kapil Kumar Goel2
1Shree Dev Bhoomi Institute of Education Science and Technology, Dehradun
2Department of Pharmaceutical Sciences, Gurukul Kangri Deemed to Be University, Haridwar-249404
juglanshalini2206@gmail.com

Innovative strategies for enhancing the transport of bioactive compounds with pharmaceutical and cosmetic applications have been made possible by nanotechnology. Among its many biological effects include lipolysis, antioxidant activity, central nervous system stimulation, and anti-cellulite properties. Caffeine is a hydrophilic xanthine derivative. Its quick clearance and low permeability, however, restrict its use in pharmaceuticals and cosmetics. Hyalurosomes, lipid vesicular nanocarriers functionalized with hyaluronic acid (HA), were created and improved for dual applications utilizing the Box–Behnken Design (BBD) in order to overcome these constraints. Hyalurosomes loaded with caffeine were made via thin-film hydration followed by sonication. with responses including particle size, polydispersity index (PDI), and entrapment efficiency, Box–Behnken Design was used to enhance important formulation parameters such phospholipid concentration, HA content, and sonication time. Using transmission electron microscopy for morphology, UV-Vis spectrophotometry for entrapment efficiency, and dynamic light scattering for particle size and zeta potential, the improved formulation was described. Initial findings showed that the nanosized vesicles (~120–180 nm) had a negative zeta potential, high entrapment efficiency, and a uniform distribution (PDI < 0.3), indicating good stability. Studies on in vitro release showed that caffeine has a 24-hour sustained release profile. Incorporation into a hydrogel base further improved applicability and potential dermal retention. Studies on stability, ex vivo skin penetration, and antioxidant evaluation are ongoing and will shed more light on long-term efficacy and clinical significance. All things considered, caffeine-loaded hyalurosomes provide a potential dual-purpose nanocarrier technology that combines the moisturizing and targeting qualities of HA with the therapeutic properties of caffeine.The caffeine-loaded hyalurosomes effectively combined the therapeutic potential of caffeine with the moisturizing and permeation-enhancing properties of HA. Pharmaceutical relevance was evident from controlled release and improved bioavailability, while cosmeceutical benefits included enhanced hydration, anti-aging, and anti-cellulite effects.

**Keywords:** Caffeine, hyalurosomes, hyaluronic acid, Box–Behnken Design

**FORMULATION & EVALUATION OF FAMOTIDINE TRANSDERMAL PATCHES BY USING NATURAL POLYMERS**

Arava Sowmya, V.L. Vinod Kumar
Department of Pharmaceutics, V.V. Institute of Pharmaceutical Sciences, Sheshadri Rao knowledge village, Gudlavalleru, Andhra Pradesh, India-521356
aravasowmya119@gmail.com

The objective of the present study was to formulate and evaluate transdermal patches of Famotidine using different polymers to enhance bioavailability and maintain a controlled drug release. Famotidine, a histamine H2-receptor antagonist with low oral bioavailability due to first-pass metabolism, is a suitable candidate for transdermal drug delivery. Transdermal patches were prepared by the solvent casting method using various polymers such as Guar gum, Xanthan gum, and Acacia in different ratios. The prepared patches were evaluated for their physicochemical parameters including thickness, weight variation, folding endurance, drug content, moisture uptake, and in vitro drug release. The results showed that the type and concentration of polymer significantly influenced the patch characteristics and drug release profile. Among all formulations, the patch containing Xanthan gum and Guar gum in an optimized ratio exhibited desirable release kinetics and mechanical properties, making it a promising candidate for effective transdermal delivery of Famotidine.

**Keywords:** Transdermal Patch, Solvent Casting Method, Guar gum, Xanthan gum, Acacia.

**PC-483**

**TARGETED INTRANASAL DELIVERY OF AGMATINE VIA LACTOFERRIN-FUNCTIONALIZED CHITOSAN NANOPARTICLES FOR ALZHEIMER'S THERAPY**

TANVI DINESH PREMCHANDANI
Department of Pharamceutics, Smt. Kishoritai Bhoyar College of Pharmcy, Kamptee, Nagpur, Maharashtra, India-441002.

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by cognitive deterioration and memory deficits, with therapeutic outcomes constrained by inadequate drug penetration across the blood–brain barrier (BBB). This study reports the formulation and evaluation of lactoferrin-conjugated, agmatine-loaded chitosan nanoparticles (Lf-Ag-CS NPs) as an intranasal delivery platform to enhance brain targeting in AD therapy. Nanoparticles were fabricated via ionic gelation and functionalized with lactoferrin through EDC/NHS-mediated carbodiimide coupling to facilitate receptor-mediated transcytosis. Optimized Lf-Ag-CS NPs exhibited a mean particle size of 337.4 nm, polydispersity index of 0.308, zeta potential of –26.6 mV, agmatine entrapment efficiency of 71–82.6%, drug content of 35.50–41.30 ± 0.50%, coupling efficiency of 79.2%, ex vivo permeation of 97.29 ± 1.3% at 5 h, and mucoadhesion potential of 57.63%, supporting efficient nasal mucosal transport. In vivo pharmacodynamic evaluation in an $AlCl_3$-induced AD rat model demonstrated that $AlCl_3$ exposure significantly impaired cognitive performance and elevated anxiety-related behaviors. Intranasal administration of agmatine solution produced minimal improvement, while non-conjugated agmatine–chitosan nanoparticles yielded moderate recovery. Lf-Ag-CS NPs markedly enhanced memory indices and attenuated anxiety behaviors, with outcomes approaching those of healthy controls, as determined by Elevated Plus Maze, Open Field Test, and Novel Object Recognition paradigms. These findings indicate that lactoferrin conjugation substantially improved brain bioavailability via receptor-mediated transcytosis and enhanced mucosal retention. Intranasal administration enabled direct nose-to-brain delivery, circumventing the BBB and minimizing systemic exposure. Collectively, Lf-Ag-CS NPs represent a promising, non-invasive therapeutic approach for the management of AD.

**PC-484**

**DEVELOPMENT OF FLUCLOXACILLIN AND CURCUMIN LOADED SMART HYDROGEL THROUGH DESIGN OF EXPERIMENTS**

Sumaiya Anjum G A, M. Padmasree, B A Vishwanath
Department of Pharmaceutics, Aditya Bangalore Institute of Pharmacy Education and Research, Yelahanka, Bangalore, Karnataka, India-560064.
anjumannu49@gmail.com

Wound healing is a complex biological process comprising hemostasis, inflammation, proliferation, and remodeling, where timely restoration of tissue integrity is critical. Smart hydrogels, with their three-dimensional polymeric networks and high-water content, provide a moist environment, enhance drug retention, and enable controlled release, making them highly suitable for wound management. The present study focused on the development of a smart hydrogel loaded with Flucloxacillin (BCS Class II, antibacterial) and Curcumin (BCS Class IV, anti-inflammatory and wound-healing agent) to achieve synergistic effects.

ISBN: 978-81-980623-8-3

The hydrogel was prepared by physical crosslinking using Poloxamer 407 as a thermo-responsive polymer, polyvinyl alcohol (PVA) as a gelling agent, sodium alginate as a crosslinker, and ethanol as a co-solvent. Formulations were evaluated for pH, drug content, entrapment efficiency, viscosity, gelation time, and in-vitro drug release, while a Design of Experiment (DoE) approach was applied to optimize formulation parameters. The optimized hydrogel showed a viscosity of 7524 cP, entrapment efficiency of 81.44%, and skin-compatible pH of 5.16. In-vitro studies revealed sustained release, with the dual-drug system performing better than single-drug formulations. The results suggest that this smart hydrogel can be a promising wound care option, as its combined antibacterial and anti-inflammatory effects promote faster healing and lower infection risk. Furthermore, the thermo-responsive gelation of the smart hydrogel enables site-specific controlled delivery, indicating potential for improved therapeutic efficacy in managing acute and chronic wounds.

**Keywords:** Wound healing, Smart hydrogels, Curcumin, Flucloxacillin, Design of Experiment.

**DESIGN AND OPTIMIZATION OF PALBOCICLIB MUCOADHESIVE BUCCAL PATCHES FOR ORAL CANCER THERAPY**

Shaikh Mufassir Jawed, M. Hassan Dehghan
Department of Pharmaceutics, Y.B. Chavan college of pharmacy, Chh. Sambhajinagar
(Aurangabad), Maharashtra, India- 431001
Shaikhmufassir23@gmail.com

An innovative mucoadhesive buccal patch for palbociclib, an anticancer drug, was designed and developed to treat oral cancer. The primary goal was to improve drug bioavailability and therapeutic effectiveness by leveraging the buccal route to bypass the hepatic first-pass metabolism and enable targeted drug delivery, thereby reducing systemic toxicity to healthy cells. The study used a Quality by Design (QbD) approach, starting with the identification of Critical Quality Attributes (CQAs) and the selection of suitable excipients, specifically a mixture of polyvinyl alcohol (PVA), hydroxypropyl methylcellulose (HPMC E15), and carboxymethylcellulose sodium (NaCMC). Drug-excipient compatibility was confirmed through FTIR and DSC analyses, which showed no significant chemical interactions. Preliminary batches were prepared and evaluated for characteristics like weight variation, thickness, folding endurance, surface pH, swelling index, and mucoadhesive strength. The formulation was then optimized using a Box-Behnken Design (BBD) to study the influence of the polymer concentrations on the mucoadhesive strength and in vitro drug release. The optimized F7 batch demonstrated high mucoadhesive strength (46 ± 1.43 g) and a significant cumulative drug release of 95.03 ± 0.22% within five hours.In conclusion, this research successfully developed a mucoadhesive buccal patch for palbociclib with desirable properties for targeted and sustained delivery in oral cancer therapy, demonstrating a promising alternative to conventional treatments.

**Keywords:** Mucoadhesive Buccal patch, Palbociclib, Oral cancer, QbD, Target drug delivery.

**PC-486**

**DEVELOPMENT OF AN INNOVATIVE SMART PHARMACEUTICAL PACKAGING SYSTEM USING THERMOCHROMIC PIGMENT FOR REAL-TIME TEMPERATURE MONITORING**

Chetan M. Rajote, Swaroop R. Lahoti
Department of Pharmaceutics, Y. B. Chavan College of Pharmacy, Ch. Sambhajinagar (Aurangabad), Maharashtra, India – 431001
chetanrajote0718@gmail.com

Proper storage of pharmaceutical products is critical to maintain their safety, efficacy, and shelf life. Many drugs, especially temperature-sensitive formulations like insulin, vaccines, and antibiotics, degrade when exposed to high temperatures. However, most current packaging systems lack a user-friendly method to visually indicate such temperature breaches to patients or healthcare workers. This project introduces a novel, cost-effective, easy to use and dual-mode smart packaging system utilizing thermochromic pigments coated with polymeric coating that respond visibly to temperature changes, this label shows both the reversible and irreversible color change. This smart packaging proactively alerts users to any breach of recommended storage conditions during storage, transportation or use, ensuring enhanced drug safety. Not only It has visual dual-color alert mechanism but also the integration of a QR code-based interactive layer. Upon scanning the QR code, users are guided through a short video or message explaining the color meaning, product safety status, and instructions for next steps. This transforms traditional packaging into a "talking" or smart-communicating packaging system. The materials are inexpensive, non-toxic, and can be easily integrated into pharmaceutical labels, blister packs, or outer cartons as simple visual patches. This innovation aims to bridge the critical gap between drug safety and user awareness, improving public health outcomes through smart, patient-friendly design.

**Keywords:** Thermochromic pigments, QR code, Temperature Monitoring, Smart packaging system.

**PC-487**

**INNOVATIVE FORMULATION AND EVALUATION OF SUMATRIPTAN FAST DISSOLVING TABLETS THROUGH $3^2$ FACTORIAL DESIGN**

Sree Kavya.J, Sk.Aminabee
Department Of Pharmaceutics , V.V.Institute Of Pharmaceutical Sciences,
Andhra Pradesh, India-521356
Sreekavya2468@Gmail.Com

In this study, the objective aims to develop and analyse fast-dissolving tablets (FDTs) of sumatriptan using super disintegrants primojel and crospovidone by direct compression technique in each case tri concentrations of super disintegrant ( 3,4 and 5 % ) where used in the preparation of FDT's.The tablets prepared were analysed for disintegration rate, disintegration time, hardness, friability, and drug concentration. The following conclusions are derived from the obtained results. A 3-level-2-factorial experimental design is chosen to specify the percentage of the independent variables primojelcrospovidone that were included in the formulation of sumatriptan Fast Dissolving Tablets. All FDTs prepared disintegrated with in 34 sec. Among the nine formulations F9 gave 100% drug release 6 min. All of the prepared FDTs led sumatripan to dissociate rapidly. In each instance , the levels of super disintegrant increased along with the sumatriptan's rate of disintegration. A series of equations were generated for disintegration time (DT), percent drug disintegrated in 10 min (PD10) . Y1= 74.00 - 7.83 X1 -22.67 X2-2.75 X1X2 +1.50X12 -6X22 (DT) , Y2=96.22 + 3.17X1 +5.33 X2 -2.50 X1X2 +1.71X12 -4.33 X22 (PD10m). The findings indicate that a higher concentration of super disintegrants results in a shorter disintegration time for the dosage form, and that a suitable selection of X1 and X2 levels can alter the drug release pattern. To check the validity of equation DT was selected for 40 sec and PD10 for 98.00. The Final Formula DT Values and PD10 were found to be 39 sec and 98.64 % indicating the validity of equation. Thus sumatriptan tablets could be successfully prepared using primojel and Crospovidone using $3^2$ Factorial Design.

**Keywords:** Sumatriptan, $3^2$ Factorial Designs, Fast Dissolving Tablets.

**SOLUBILITY AND DISSOLUTION RATE ENHANCEMENT OF LOPINAVIR BY SOLID DISPERSION AND SOLID LIPID MICROPARTICLE TECHNIQUES**

J. Navyasri, T. Balakrishna.
Department of Pharmaceutical Sciences, V.V. Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh, India - 521356
jallurinavyasri@gmail.com

The present investigation is mainly focused on enhancing the solubility of poorly soluble drug Lopinavir by formulating it as solid dispersions and solid lipid microparticles. Solid lipid microparticles are prepared by using Glyceryl monostearate, Phospholipon 90 H, Lipoid S 100, Compritol ATO 888 by solvent evaporation and homoenisation. Solid dispersions of Lopinavir were prepared by using Soluplus and KollidonVA64, glyceryl monostearate (GMS), Phospholipon 90 H, Lipoid S 100 as carriers by solvent evaporation method and kneading method. Further, solid lipid microparticles and solid dispersions were subjected to in vitro dissolution tests in order to study the drug release profiles of Lopinavir. Rapid drug release of Lopinavir was achieved with the lipid microparticles and solid dispersions prepared with the different types of excipients. The optimized formulations were further characterized by

ISBN: 978-81-980623-8-3

XRD, DSC, SEM, and FTIR analysis to find out drug and excipients interactions. These studies revealed that the formulations were stable.

**Keywords:** Solid Lipid Microparticles, Soluplus and KollidonVA64, Glyceryl Monostearate (GMS), Phospholipon 90 H, Lipoid S 100.

**DESIGN AND IN-VITRO EVALUATION OF FAST DISSOLVING FILMS CONTAINING DOXYLAMINE SUCCINATE**

Jayasree.B, T.Balakrishna,
Department of Pharmaceutical sciences, V.V.Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh, INDIA -521356
Jayasreebatchu413@gmail.com

The present study deals with the formulation of fast dissolving films of Doxylamine succinate is an antihistaminic commonly used for the prevention and treatment of Nausea and Vomiting in pregnancy. Doxylamine is a Histamine H1 antagonist with pronounced sedative properties. It is used in allergies, antiemetic, and hypnotic. Doxylamine has also been administered in veterinary applications and was formerly used in Parkinsonism. The concept of fast-dissolving drug delivery emerged from the desire to provide patient with more conventional means of taking their medication. In the present research work, various trials were carried out using film forming agents such as maltodextrin, gum karaya and xanthan gum to prepare an ideal film. Emulsion evaporation method was used for the preparation of films. The prepared films were evaluated for weight uniformity, drug content, film thickness, folding endurance, dispersion test and curling. The in vitro dissolution studies were carried out using simulated salivary fluid (pH 6.8 phosphate buffers). About 98% of the drug was found to be released from the film prepared with the drug excipient interaction studies carried out by differential scanning calorimetry analysis and Fourier transform infrared studies and the results revealed that there were no major interactions between the drugs and excipients used for the preparation of films.

**Keywords:** Emulsion evaporation method, fast dissolving films, gum karaya, maltodextrin, of Doxylamine succinate, xanthan gum.

**DUAL-LIGAND FUNCTIONALIZED LIPID NANOPARTICLES FOR EFFICIENT DNA TRANSFECTION IN BREAST CANCER THERAPY**

M.N.S.Divya sri. Dr.T.Balakrishna
V.V.Institute of Pharmaceutical Sciences, Seshadri Rao Knowledge Village ,Gudlavalleru, Andhra Pradesh, INDIA-521356,
sirimamillapalli2005@gmail.com

Lipid nanoparticles (LNPs) have emerged as efficient non-viral carriers for gene delivery due to their high loading capacity, biocompatibility, and low immunogenicity. In this study, DNA-loaded LNPs were engineered for targeted delivery to HER2-positive breast cancer cells. Targeting was achieved through trastuzumab (Herceptin®), a monoclonal antibody directed against the extracellular domain of HER2, in combination with folate to overcome intrinsic trastuzumab resistance and enhance cellular uptake. Dual-targeted LNPs encapsulating plasmid DNA encoding fluorescent reporter proteins (tdTomato or EGFP) were prepared using folate-conjugated PEGylated lipids, followed by surface conjugation with thiolated Herceptin. At an N/P ratio of 6, the resulting nanoparticles were small, uniform, and exhibited a slightly negative potential. In vitro studies using breast cancer cell lines (MCF7, MDA-mb453, SKBR3) revealed that nanoparticle uptake correlated with HER2 expression levels and was significantly enhanced with dual targeting. Transgene expression was consistently higher in dual-targeted systems compared to single-targeted controls. Furthermore, in vivo zebrafish xenograft models demonstrated superior targeting and transfection efficiency under physiological conditions. These findings highlight the potential of dual-targeted LNPs as a promising strategy for improved gene delivery in HER2-positive breast cancer.

**Keywords:** Trastuzumab, Herceptin Folate, Targeting Lipid nanoparticles, DNA gene delivery

**NIOSOMAL NANOCARRIERS OF MEBEVERINE HYDROCHLORIDE: EFFECT OF POLOXAMER AND SOLUPLUS ON STABILITY AND DRUG RELEASE**

Ch.Charitha Sri Lakshmi and T Balakrishna
Department of Pharmaceutical sciences, V.V.Institute of pharmaceutical sciences, Gudlavalleru, Andhara Pradesh, India- 521356
chandikacharithasrilakshmi@gmail.com

Mebeverine hydrochloride (MBHCl) is an antispasmodic that needs to be administered frequently due to its short half-life and low oral bioavailability. In order to improve drug entrapment, stability, and sustained release, niosomal formulations were created utilising Span 60, cholesterol, poloxamer 188, and Soluplus in different ratios. Span 60: Cholesterol ratios ranging from 1:0.5 to 1:1.5% were used to develop eight formulations. Poloxamer 188 was added as a stabiliser at 0.1–0.3 parts, and Soluplus was used as a surface coating at 0.05–0.2 parts. The thin film hydration technique and probe sonication were used to prepare the niosomes. Particle size, polydispersity index, zeta potential, entrapment efficiency (EE%), and in vitro drug release were all assessed for the formulations. Good colloidal stability was indicated by zeta potential values in the range of -25 to -40 mV and particle sizes ranging from 120 to 240 nm with PDI <0.25. Higher cholesterol ratios and the presence of Soluplus enhanced entrapment efficiency, reaching up to 78% EE. DSC thermograms showed decreased drug crystallinity, indicating effective encapsulation within the niosomal bilayers, whereas FTIR spectra verified the lack of chemical interaction between MB HCl and excipients. In contrast to the quick release from pure drug solution, in vitro release tests in phosphate buffer (pH 6.8) showed persistent release of MBHCl over a 12-hour period. The ideal combination of high entrapment, nanosize stability, and extended release was offered by the optimized formulation (Span 60: Cholesterol 1:1, Poloxamer 0.2, Soluplus 0.1). These results imply that niosomes made with a poloxamer/Soluplus modification and Span 60-cholesterol backbones constitute a viable nanocarrier technology to enhance the therapeutic efficacy of mebeverine HCl.

**Keywords:** Mebeverine hydrochloride, Niosomes, Poloxamer 188, Soluplus, Thin film hydration, entrapment efficiency.

**INFLUENCE OF NATURAL POLYMERS ON ZOLMITRIPTAN ORAL FAST DISSOLVING FILM FORMULATIONS: A NEW APPROACH TO MIGRAINE TREATMENT**

VendraSirisha, T.Balakrishna
Department of Pharmaceutics,V.V.Institute of Pharmaceutical Sciences,Seshadri Rao knowledge village,Gudlavalleru,Andhra Pradesh,India-521356
sirisha.vendra1@gmail.com

Migraine is a debilitating neurological disorder often accompanied by symptoms like nausea, vomiting, and difficulty swallowing, which limit the effectiveness of traditional oral medications. Fast dissolving oral films (FDFs) offer a convenient, water-free drug delivery method ideal for such patients. This study developed and evaluated zolmitriptan-loaded FDFs using natural polymers—Gum Karaya and Gum Olibanum—along with glycerin as a plasticizer, and citric acid and stevia as stabilizers. Films were prepared via solvent casting and assessed for thickness, weight uniformity, folding endurance, and drug content. In vitro drug release using a Franz diffusion cell (pH 6.8 buffer) revealed that the optimized formulation (Z7) achieved 98.99% drug release within 5 minutes. FTIR analysis confirmed no drug–excipient interaction, and DSC analysis demonstrated thermal stability of the components. The combined use of natural gums enhanced solubility, mechanical strength, and dissolution rate. Overall, zolmitriptan FDFs offer a promising, fast-acting alternative for effective migraine management.

**Keywords:** Zolmitriptan, Oral fast dissolving films, Solvent casting method, polymers and plasticizers

Silver nanoparticles (AgNPs) are widely used in healthcare due to their strong antimicrobial and anti-inflammatory activities, making them promising candidates for wound healing applications. The present study focuses on the green synthesis of AgNPs using Woodfordia fruticosa gel

ISBN: 978-81-980623-8-3

and β-sitosterol, followed by the formulation of a nanoparticle-based gel for enhanced therapeutic efficacy. A 1 mM silver nitrate solution was prepared by dissolving 16.99 mg in 100 ml of distilled water and utilized along with β-sitosterol and Woodfordia fruticosa gel for nanoparticle synthesis. The obtained AgNPs were characterized by UV–visible spectrophotometry and scanning electron microscopy (SEM) to confirm formation and morphology. Further evaluation of zeta potential and electron microscopy was performed to assess stability and physicochemical properties. The AgNPs were incorporated into a gel formulation, which was subsequently evaluated for its potential wound-healing application. The synthesis process successfully produced stable AgNPs mediated by natural compounds. Characterization confirmed nanoparticle formation with favorable morphology and size. Zeta potential analysis indicated good stability, while SEM validated the structural features of the nanoparticles. The formulated gel demonstrated desirable properties suitable for topical application.The study demonstrates the successful green synthesis and formulation of a silver nanoparticle gel using β-sitosterol and Woodfordia fruticosa. This biocompatible approach reduces toxicity concerns while enhancing wound-healing potential through synergistic antimicrobial and anti-inflammatory effects, highlighting its promise in biomedical applications.

**Keywords:** Silver nanoparticles β-sitosterol,Woodfordia fruticosa,Zeta potential analysis.

**FORMULATION AND EVALUATION OF MEDICATED BIODEGRADABLE SURGICAL SUTURES BY USING NATURAL FIBERS**

Y.Raga Priyanka, V. L. Vinod Kumar
Department of Pharmaceutics, Vallabhaneni Venkatadri Institute of Pharmaceutical Sciences, Gudlavalleru Andhra Pradesh, India-521356.
yarrapothuragapriyanka@gmail.com

The optimized F3 formulation was developed using a combination of three polymers i.e Hydroxy propyl Methylcellulose (HPMC), Chitin and Alginate - incorporated with natural cotton fibre (cellulose) as the base material. This formulation exhibited excellent physicochemical and mechanical properties, including controlled thickness, high tensile strength, minimal swelling and ensuring structural integrity. Drug content analysis confirmed high encapsulation efficiency (98.9%), while in vitro release studies demonstrated sustained drug release of Azithromycin and Mefenamic Acid, enhancing therapeutic potential. Sterility testing validated its microbial safety, and Scanning Electron Microscopy (SEM) analysis revealed a well-defined surface morphology, essential for biomedical applications. These findings suggest that the F3 formulation is a promising candidate for advanced wound healing and surgical applications.

**Keywords:** Biomedical Applications, Surface Morphology, Scanning Electron Microscopy (SEM), Tensile Strength, Encapsulation Efficiency.

**PACKAGING STRATEGIES FOR STABILITY ENHANCEMENT OF SENSITIVE ANTIBIOTIC FORMULATIONS: A COMPREHENSIVE REVIEW**

Vaibhav Kore, Mahesh Patil, Jayshree Taksande, Milind Umekar, Vinita Kale
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee
Rashtrasant Tukdoji Maharaj Nagpur University, Nagpur – 441002
korevaibhav221@gmail.com

The stability and efficacy of sensitive antibiotics are significantly influenced by packaging systems and environmental factors. With increasing concerns about antimicrobial resistance, optimizing existing antibiotic formulations through advanced packaging strategies has become crucial for maintaining therapeutic effectiveness and extending shelf life. This review examines current approaches to packaging and stability optimization for sensitive antibiotic formulations, focusing on environmental barrier technologies, advanced packaging materials, and stability; indicating analytical methods that preserve antibiotic potency throughout the product lifecycle. A comprehensive analysis of pharmaceutical packaging technologies, stability testing protocols, and regulatory guidelines was conducted, examining both traditional and innovative approaches to antibiotic preservation. Major environmental degradation pathways including hydrolysis, oxidation, photodegradation, and microbial contamination were evaluated in the context of packaging solutions.

**Keywords:** Antibiotic stability; sensitive antibiotics; packaging optimization; packaging strategies; active packaging; shelf-life extension.

**DEVELOPMENT AND IN VITRO CHARACTERIZATION OF FLOATING TABLETS CONTAINING OLMESARTAN MEDOXOMIL**

MohammadFarheena sulthana, Lakshmana Vinod kumar
Department of Pharmaceutical Sciences,V.V.Institute of Pharmaceutical Sciences, Gudlavalleru, Andhra Pradesh,India -521356.
farheenamd3@gmail.com

In this current research, aimed to make floating Olmesartan medoxomil tablets that remain long in the stomach and gradually release drug within the time. This aids in the constant level of drug in the body. The release of the drug was controllable by using various polymers such as Hydroxy Propyl Methyl Cellulose (HPMC), Carbopol, and Hydroxy Propyl Cellulose (HPC). Olmesartan medoxomil is a drug used to treat elevated blood pressure. It falls in a category of medication known as angiotensin II receptor blockers. It is a prodrug hence it is broken down to its active form (Olmesartan) inside the stomach. It is further not metabolized and does not combine with liver enzymes (CYP450). Because of this, making it into a floating tablet is useful. These tablets have an ability to limit the side effects and enhance the efficacy of the drug by facilitating the slow release. The hardness of the prepared tablets was measured, friability (breakability), the content of the drug was determined, its floating, release of a drug, its swelling ability, and stability were also tested.

**Keywords:** Olmesartan medoxomil, High Blood Pressure, Floating tablet, Gastroretentive Drug Delivery

**PC-497**

**FORMULATION DEVELOPMENT AND INVITRO ASSESSMENT OF SPARFLOXACIN TABLETS**

M. Meghana, Sk.Aminabee
Department of Pharmaceutical Sciences, V. V. Institute Of Pharmaceutical Sciences, Gudlavalleru, Krishna District, A.P, India – 521356.
meghanamittapalli127@gmail.com

Sparfloxacin represents the fourth step in the development of the quinoline antibacterial agents. The antibacterial spectrum of sparfloxacin is wider than those of the third step quinolones having limited activity against staphylococci, pneumococci, and mycoplasma. Sparfloxacin is 10-20 times more potent than ciprofloxacin, ofloxacin and lomefloxacin against commonpathogens. It is a synthetic broad spectrum antimicrobial agent for oral administration. It is very sparin glysoluble in waterlike other flouroquinolone agents.The very poor aqueous solubility and wettability of the sparfloxacin give rise to difficulties in pharmaceutical formulations of oral dosage forms and may lead to poor bioavailability. To overcome these drawbacks, increasing the aqueous solubility is an important goal and hence in the present investigation, sparfloxacin was formulated as solid dispersion systems and physical mixtures with the aim to improve its pharmaceutical properties like aqueous solubility, dissolution rate and oral bioavailability.

**Keywords:** Sparfloxacin, Solubility enhancement, Dissolution rate, Oral bioavailability

**PC-498**

**INDUSTRIAL SCALE-UP AND OPTIMIZATION OF NANOEMULSION GEL FOR TOPICAL DELIVERY**

Dipti Patel, Prashant Gupta
Department of Pharmaceutics, Institute of Pharmaceutical Sciences, Faculty of Pharmacy, Parul University, Waghodia, Vadodara, Gujarat, India-391760
dipti.patel@paruluniversity.ac.in

The present study was designed to develop, optimize, and industrially scale-up a nanoemulsion-based gel for topical delivery. A Quality by Design (QbD) approach was adopted to identify critical material attributes (CMA) and critical process parameters (CPP) that influence product performance, including droplet size, zeta potential, viscosity, and stability. Using an I-Optimal mixture design, the nanoemulsion system was optimized for clarity, stability, and particle size, and subsequently incorporated into a Carbopol 940 gel matrix to enhance viscosity, bioadhesion, and skin compatibility. The optimized formulation

ISBN: 978-81-980623-8-3

exhibited improved drug release, ex vivo permeation, and in vivo safety compared with conventional topical preparations. To demonstrate industrial feasibility, the batch was successfully scaled up ten-fold (800 g), with critical CPPs such as aqueous phase addition rate and homogenization speed carefully controlled. Scale-up batches retained consistent critical quality attributes relative to laboratory batches, with droplet size (~217 nm), zeta potential (~26 mV), viscosity, and bioadhesive strength meeting specifications. Stability studies conducted under ICH guidelines confirmed the robustness of the formulation, with no evidence of phase separation, degradation, or structural changes during storage.This work demonstrates successful translation of nanoemulsion gel development from laboratory to production scale, validating its potential as a reliable, safe, and scalable platform for topical delivery applications.

**Keywords:** Nanoemulsion Gel, Scale-Up, QbD, Critical Quality Attributes, Technology Transfer, Topical Delivery.

**PC-499**

**NANOCRYSTAL FORMULATION OF CARBAMAZEPINE USING HIGH-SPEED HOMOGENISATION FOR IMPROVED SOLUBILITY**

Karthika.P, Gayathri.R
Department of Pharmaceutics, Dr Kalam College of Pharmacy, Avanam, Thanjavur, Tamil Nadu, India -614623.
karthika21504@gmail.com

In this study, an high speed homogenisation followed by lyophilisation was developed to produce nanocrystals of carbamazepine (CBZ), a poorly water soluble drug, for solubility rate enhancement of CBZ include compaction with HPMC-K100, Poloxamer-188, Ethyl cellulose formation of nanosuspension followed by lyophilisation with highly hydrophilic carrier such as mannitol to prevent particle agglomeration in powdered state. Nanocrystals were characterized in terms of drug content, particle size & zeta potential and saturated solubility were investigated and compared to the pure drug CBZ to verify the theoretical hypothesis on the benefits of increased surface area. Crystalline state were evaluated by scanning electron microscope (SEM) and x-ray powder diffraction (XPRD) analysis. Through this study, nanocrystals formulation can improve the bioavailability of the carbamazepine by improving its solubility when compare to pure drug. Hence it was concluded that nanocrystallisation was a good approach to enhance the solubility property of carbamazepine by High speed homogenization method. The method being simple and easily scaled up, this approach should have a general applicability to many poorly water-soluble drug entities.

**Keywords:** Poorly water-soluble drug carbamazepine, high speed homogenisation, nanosuspension, lyophilisation, nanocrystal.

**FORMULATION DEVELOPMENT AND EVALUATION OF INTRANASAL NANOEMULSION OF AGMATINE FOR THE TREATMENT OF EPILEPSY**

Sagar Bawankar, Vipin Wankhede, Jayshree Taksande, Milind Umekar, Mohammad Qutub
Smt. Kishoritai Bhoyar College of Pharmacy, R.T.M.N. University, Nagpur, Maharashtra, India-441002
sagarbawankar123@gmail.com

Epilepsy is a chronic neurological disorder characterized by recurrent, unprovoked seizures that result from abnormal and excessive neuronal discharges in the brain. Despite the availability of several antiepileptic drugs, many patients continue to experience uncontrolled seizures due to poor bioavailability, drug resistance, and systemic side effects. Therefore, the development of alternative drug delivery systems is essential to improve therapeutic outcomes. The aim of this study was to develop agmatine sulphate nanoemulsion for intranasal administration in the treatment of epilepsy. The nanoemulsion was prepared using an aqueous titration method and probe sonication, with olive oil as the oil phase, span 80 and tween 80 as the surfactants. The formulation was optimized based on a pseudoternary phase diagram, and D-optimal design was employed to optimize the independent variables (oil, Smix, and water) and the dependent variables (drug content and viscosity). The optimization data were analysed using Design-Expert software 13. The prepared agmatine sulphate nanoemulsion was characterized for various parameters including stability, particle morphology, particle size, polydispersity index (PDI), zeta potential, centrifugation, heating cooling cycle, drug content, pH, viscosity, in vitro drug diffusion, ex vivo permeation, and ex vivo biocompatibility studies using excised goat nasal mucosa. The results showed that the agmatine sulphate nanoemulsion had a particle size of 265.4 nm, indicating its suitability for nasal drug delivery. The low PDI value of 0.240 indicated a narrow size distribution, and the pH of 6.4 was suitable for nasal administration. The nanoemulsion exhibited high permeation, without any morphological toxicity observed on the excised goat nasal mucosa. In conclusion, the prepared agmatine sulphate nanoemulsion was found to be suitable for intranasal administration, offering the potential to enhance drug absorption and bioavailability. This formulation may have promising implications for the treatment of epilepsy and other related neurological conditions.

**Keywords:** Agmatine, Nanoemulsion, Pseudoternary phase diagram, Epilepsy, Intranasal administration

**DESIGN AND EVALUATION OF CONTROLLED RELEASE FLOATING MICROBALLOONS OF STAVUDINE**

M. Naga Jyothi, T. Balakrishna, T. Sravani, VL. Vinod Kumar
V. Rajani, M. Harika
Department of Pharmaceutics, V.V. Institute of Pharmaceutical Sciences, Seshadri Rao Knowledge Village, Gudlavalleru, Andhra Pradesh, India -521356
msivallakshmimsl@gmail.com

The Aim of this study was to formulate and evaluate stavudine floating microballoons for Controlled drug release. Initially drug loaded low density granular pellets were prepared with HPMCE 5 and by using isopropyl alcohol as a granulating fluid. Further the low density granular Pellets were subjected to microencapsulation by emulsion evaporation technique using ethyl cellulose and Eudragit S100 as coating polymers and 1%PEG as aqueous phase. The prepared microballoons were characterized for their particle size analysis, angle of repose and for compressibility index. The in vitro release studies were performed in 0.1NHCl as acidic medium. The prepared microballoons were free flowing and spherical in shape. From all the formulations F5E and F5F can be considered as a promising controlled release floating microbaloons of stavudine providing first order release over a period of 12 hours, with minimum floating Lag time of 1 minute. It was found that the drug: polymer, the stirring speed, the concentration of surfactant were the most significant variables which influenced the size of the stavudine microbaloons under the applied experimental condition.

**Keywords:** Stavudine, HPMC E 5 Controlled Release, Eudragit S 100.

**FORMULATION AND EVALUATION OF NANOEMULGEL USING COW URINE DISTILLATE FOR PSORIASIS**

Prajakta Boharapi, Gauravi Sewatkar, Ruchi Khobragade, Jayshree Taksande, Milind Umekar
Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur 440001
prajaktaboharapi@gmail.com

Psoriasis is a chronic inflammatory skin disease characterized by oxidative stress, immune dysregulation, and hyperproliferation of keratinocytes. This study aimed to develop a novel nanoemulgel formulation incorporating cow urine distillate (CUD) for the topical treatment of psoriasis, leveraging its antioxidant and anti-inflammatory properties, as well as its immunomodulatory and wound-healing capabilities. However, CUD presents certain limitations such as susceptibility to oxidation, unpleasant odour and taste, and challenges in patient compliance. To address these issues, developing a novel, stable, and patient-friendly formulation is essential. A nanoemulgel system was designed by combining nanoemulsion technology with a gel matrix to enhance skin permeation, drug retention, and sustained release. Castor oil served as the oil phase due to its compatibility with CUD, while Span 80 acted as a surfactant, Carbopol 940 as a gelling agent, and triethanolamine adjusted the pH. Preliminary studies included characterization of CUD, solubility analysis, and FTIR spectroscopy to ensure compatibility with excipients. Using Design-Expert software and a Central Composite Design, 15 batches were formulated to optimize variables, including surfactant concentration, gelling agent, and sonication time. Optimized batch F14 exhibited

ISBN: 978-81-980623-8-3

favourable properties, with a pH of 5. 90 ± 0. 03, spreadability 47. 94 ± 0. 06 g- cm/s, viscosity 8823. 33 ± 25. 17 cP, and sustained drug release (80. 80.21 ± 0. 26% in 8 hours). Nanoemulgel droplet size was 487. 9 nm with a PDI of 0. 155 and zeta potential- 21. 5 mV, indicating stability. Drug content was 82. 92 ± 0. 77%. No irritation was observed in skin irritation tests on Swiss albino mice. Histopathological analysis revealed that nanoemulgel-treated groups showed greater recovery of psoriatic symptoms compared to CUD alone. Overall, the CUD-based nanoemulgel demonstrated superior therapeutic efficacy, safety, and potential for effective topical management of psoriasis.

**Keywords:** Cow urine distillate (CUD), Nanoemulgel, Psoriasis, Sustained drug release.

## HYDROPHILIC POLYMER BASED SOLID DISPERSION: IMPROVES SOLUBILITY, DISSOLUTION AND PERMEABILITY OF RESVERATROL USING FUSION METHOD

Anshul Pande, Sakshi Itekar, Rashmi Trivedi, Milind Umekar
anshulp211@gmail.com

Resveratrol (trans-3,5,4'-trihydroxystilbene) is a naturally occurring polyphenolic compound with antioxidant, anti-inflammatory, cardioprotective, anticancer, and neuroprotective activities. However, its clinical utility is limited by poor aqueous solubility, rapid metabolism, and low oral bioavailability, classifying it as a BCS Class II drug. This study formulated solid dispersions (SDs) of resveratrol using hydrophilic polymer Poloxamer 188 via fusion method to enhance solubility, dissolution rate, and permeability. Five formulations (SD1-SD5) were developed using 100 mg resveratrol with increasing Poloxamer 188 concentrations, achieving drug-to-polymer ratios of 1:1 to 1:5. The fusion technique involved melting the polymer and incorporating drug under controlled temperature and stirring, followed by solidification and size reduction. Physicochemical characterization using FTIR, DSC, PXRD, and SEM confirmed resveratrol amorphization and uniform dispersion within the polymer matrix. Results demonstrated that Poloxamer 188-based solid dispersions effectively enhanced resveratrol's solubility, dissolution, and permeability. The optimized SD3 formulation presents a promising strategy for developing improved oral dosage forms of poorly water-soluble compounds, improving therapeutic efficacy and patient compliance. This solvent-free fusion method significantly contributes to overcoming formulation challenges associated with hydrophobic drug molecules like resveratrol.

**Keywords:** resveratrol, solubility, fusion method.

## FORMULATION AND EVALUATION OF FILM-FORMING SOLUTION OF FERULIC ACID FOR THE TREATMENT OF ATOPIC DERMATITIS

Sushank Kalyankar, Sameer Khidkikar, Jayshree Taksande, Amol Tatode, Dinesh Biyani, Milind Umekar
Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee Nagpur, Maharashtra, 441002
sushankkalyankar@gmail.com

In the present research, a film-forming solution (FFS) of Ferulic Acid (FA) was developed for the treatment of Atopic Dermatitis (AD). The objective of the study was to evaluate the potential of FFS in enhancing drug penetration, providing sustained release, and improving patient compliance in comparison to conventional topical therapies. The formulation process involved the selection and characterization of suitable film-forming polymers along with preformulation studies of FA, including organoleptic evaluation, solubility, UV, and FTIR analysis, followed by the preparation and evaluation of FA-loaded FFS. A total of thirteen formulations were prepared, among which optimized Batch 1, exhibited the highest spreadability (65 g·cm/sec), the shortest drying time (2.3 minutes), and a skin-compatible pH of 5.65±1.25. The viscosity of Batch 1 was recorded as 296±1.4 cps at 10 rpm, indicating good uniformity and film-forming ability. In vitro drug diffusion studies using Franz diffusion cells demonstrated maximum cumulative drug release of 72±0.26% at 5 hours (Batch 1), while the lowest release was observed with Batch 4 (65±0.76%). Ex vivo permeation studies on excised skin further confirmed the permeation ability of FA, 40.1±0.18% release at 5 hours. FTIR analysis confirmed the absence of drug–polymer interaction, and the transparent films obtained upon application indicated excellent cosmetic acceptability. The results demonstrated that polymer type and excipient composition significantly influenced physicochemical properties and drug release behaviour. Thus, FA-based FFS can be considered a safe, effective, and patient-friendly topical drug delivery approach for the management of atopic dermatitis.

**Keywords:** Ferulic Acid, Film-forming solution, Atopic dermatitis, Topical delivery

## DEVELOPMENT AND EVALUATION OF NIZATIDINE FLOATING NANOSPHERES WITH GASTRORETENTIVE PROPERTIES FOR PEPTIC ULCER TREATMENT

Rutuja Raghorte, Anurag Kumar Shahi, Vishwas Jibkate, Nishant Awandekar, Jayshree Taksande, Milind Umekar
Departrment of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee,
Nagpur University, Maharashtra, India – 441002

The use of nanospheres in therapeutic formulations to improve bioavailability, extend drug release, and lessen side effects has attracted considerable interest. The aim of this study was to create and enhance nizatidine gastroretentive floating nanospheres for prolong action. Using PVA as stabilizer, gastroretentive floating ethylcellulose nanospheres filled with nizatidine were created via solvent evaporation. DSC and FTIR were used to characterise the resulting nanosphere. Additionally, the drug release, entrapment efficiency, particle size, and floating behaviour were evaluated. Using ethylcellulose and sonication duration as independent factors, a 32-factorial design was used to optimise the manufactured nanosphere. The creation of spherical nanospheres with a somewhat porous surface was verified by the morphological analysis of the optimised formulations. DSC was used to characterise the nanospheres, and the results showed that nizatidine was present in the nanospheres in an amorphous form. FTIR did not show any chemical interaction between the medication and the polymer. The ideal mixture, with a particle size of 145±10.53 nm, a polydispersity index of 0.265, and a nanosphere Zeta Potential of -11 mV, was discovered. In ethylcellulose, the entrapment efficiency was determined to be 91.72%. The drug release from the nanospheres was observed to be 79.15±1.65% in gastrointestinal simulated fluid after 12 hours of modulation. The resulting nanospheres exhibit a prolonged release of the medicine and stay buoyant in the gastric fluid for a longer period of time inside the stomach.

**Keywords:** Gastroretentive floating nanospheres, Nizatidine, Anti-Ulcer activity, DSC, FTIR.

**PC-506**

## UNVEILING YOGURT BASED HYDROGELS THAT MIMICS HUMAN TISSUE AND BOOST HEALING

Vipul Meshram, Puneet Nirmal, Vandana Arora Sethi, Lalit Kumar Tyagi
Lloyd Institute of Management and Technology, Plot No: 11, Knowledge Park-II, Greater Noida, Uttar Pradesh, India- 201306
sudhanshubusiness17@gmail.com

Hydrogels are three-dimensional, hydrophilic polymeric networks capable of absorbing large amounts of water, making them suitable candidates for wound healing applications. Yogurt-based hydrogels represent an innovative and bio-inspired approach due to the natural composition of yogurt, which is enriched with lactic acid bacteria, proteins, and bioactive metabolites. These components impart antimicrobial, antioxidant, and anti-inflammatory activities that accelerate wound closure, reduce infection risk, and support overall skin repair. When incorporated into hydrogel matrices, yogurt-derived biomolecules mimic the extracellular matrix (ECM) by creating a moist and porous environment that promotes keratinocyte and fibroblast proliferation, angiogenesis, and collagen deposition—key processes in tissue regeneration. The biodegradable and flexible structure of these hydrogels further enhances cellular adhesion and proliferation while maintaining oxygen diffusion at the wound site. In addition, their potential to deliver probiotics and bioactive molecules in a controlled manner provides synergistic therapeutic benefits, making them multifunctional wound dressings. Physicochemical evaluations, including swelling index, rheological behavior, and porosity studies, confirm their structural stability and biocompatibility. Compared with synthetic dressings, yogurt-based hydrogels are cost-effective, sustainable, and eco-friendly alternatives with added biological activity.

ISBN: 978-81-980623-8-3

Recent findings highlight their dual function as both a structural scaffold and a bioactive therapeutic system capable of improving healing outcomes. Overall, yogurt-based hydrogels hold significant promise as next-generation biomaterials that combine natural bioactivity with tissue-mimicking properties. By pairing probiotic delivery with ECM-like support, they offer a novel and multifunctional strategy for wound healing and human tissue regeneration.

**Keywords:** Yogurt-based hydrogels, wound healing, tissue regeneration, biocompatible biomaterials, probiotic delivery, extracellular matrix mimicry.

Hyperhidrosis, a condition marked by excessive sweating, adversely affects daily life and requires more effective topical therapies with improved patient adherence. Aluminium chloride, a well-known astringent and antiperspirant, is widely prescribed as a first-line treatment. However, conventional formulations such as solutions and creams are often associated with poor dermal penetration, high irritation potential, and reduced patient acceptance. To overcome these limitations, the present study aimed to formulate and evaluate a nano-emulgel for enhanced topical delivery of aluminium chloride. Nanoemulsions were prepared using liquid paraffin as the oil phase, stabilized by Span 20 and Tween 80 as surfactant and co-surfactant, through high-speed stirring followed by probe sonication. The optimized nanoemulsion was subsequently incorporated into a Carbopol 940 gel base to yield a nano-emulgel with improved viscosity and spreadability. The developed formulations were evaluated for physical appearance, homogeneity, grittiness, viscosity, pH, and spreadability. Among the various batches, formulation F3 exhibited the most desirable properties, including smooth texture, excellent homogeneity, optimal skin-friendly pH (6.7), and suitable viscosity (1025.67 cps). Differential Scanning Calorimetry confirmed the crystalline nature of aluminium chloride, while in vitro studies demonstrated improved drug release and enhanced permeation through skin layers. The results indicated that the aluminium chloride-loaded nano-emulgel effectively combined the penetration-enhancing properties of nanoemulsions with the rheological advantages and patient-friendly features of gels. The optimized formulation showed controlled drug release, prolonged skin retention, and minimized irritation, suggesting its potential as a safe and effective option for hyperhidrosis management.

**Keywords:** Nanoemulgel, Aluminium chloride, Hyperhidrosis, Probe sonication, Topical drug delivery, Controlled release

As preclinical experiment finds face obstacle to patient for successful treatment of brain diseases. So, revelant models to elucidate mechanism of brain pathogenesis, cell-cell intractions, predict drug responses which are urgent need in patients. And to know BBB functions. We examined a Brain- Chip of human cortical parenchyma and BBB in one model. We utilized human Astrocyte , pericyte , human induced pluripotent stem cell (hipsc)-derived cortical neurons , hipsc derived microglia. As a result , dust model recapitulate invivo-relevant responses highlighting the Brainchips sensitivity to capture cell- specific contribuction in human diseases pathology further tested BBB crossing of human transferrin receptor antibodies. We conclude that Brain Chips is time efficient model to support therapeutic development and provide mechanistic insights into brain diseases

**Keywords:** microfluidics brain-chip; physiologically relevant responses; cell- specific contributions; screening of BBB -crossing therapeutic

Effective management of diabetes mellitus depends on insulin delivery systems capable of maintaining near-normal blood glucose while minimizing acute complications such as hypoglycemia and diabetic ketoacidosis, along with long-term vascular damage. Conventional strategies, including multiple daily injections and continuous subcutaneous insulin infusion (CSII), though widely used, often fail to achieve optimal glycosylated hemoglobin (HbA1c) levels. Moreover, CSII, despite its aim to simulate physiological insulin release, is associated with limitations such as device malfunction, metabolic variability, and risk of hypoglycemia. Other delivery tools, including pens, jet injectors, and access ports, mainly improve patient convenience without offering substantial therapeutic advancement. Artificial pancreas systems show promise but remain restricted to controlled research environments and are not yet practical for routine use. Emerging implantable insulin delivery devices and closed-loop systems integrating intraperitoneal glucose sensing and insulin infusion have attracted growing attention. Intraperitoneal delivery ensures faster glucose detection and insulin absorption compared to subcutaneous methods, thereby providing superior postprandial regulation and more stable glycemic control. Prototype devices, comprising fully implantable glucose sensors, insulin reservoirs, and adaptive control algorithms, have demonstrated encouraging outcomes in preclinical and early clinical studies, including enhanced sensing accuracy, reduced response delays, better postprandial control, and improved patient quality of life. However, several challenges must be addressed before clinical adoption. These include ensuring long-term stability of glucose sensors, material biocompatibility, prevention of catheter obstruction, infection control, and durability of insulin formulations. Despite these hurdles, the integration of advanced biosensors, programmable pumps, and intelligent feedback mechanisms offers the potential to achieve a truly implantable artificial pancreas. With sustained research, optimization, and long-term trials, such innovations may redefine diabetes care by enabling safer, needle-free, and physiologically adaptive insulin therapy.

**Keywords:** Artificial pancreas, implantable insulin pumps, intraperitoneal sensing, closed-loop delivery, glycemic regulation.

dipakbhalekar27@gmail.com

Migraine is a common and debilitating neurobiological condition characterized by recurring headaches frequently accompanied by gastrointestinal, autonomic, and neurological symptoms. This study aims to develop fast-dissolving oral thin films (FDOTFs) that enable the drug to directly enter systemic circulation, thereby bypassing first-pass metabolism, for the management of migraine. FDOTFs are prepared using the solvent casting method. The oral film formulation was optimized using a 22 factorial design. The objective behind the study was to examine and evaluate the FDOTFs. The evaluation process involved characterizing the formulation, which included thickness, weight variation, moisture content, content uniformity, surface pH, and a disintegration test. A total of nine batches were prepared (F1 to F9), and the film thickness ranged from 0.07mm to 0.21mm. in terms of weight, F3 is the lightest (40.66), while F9 is the heaviest (68.66). All formulations have surface pH values close to neutral (between 6.67 and 6.93). The oral thin film showed a disintegration time in the range of 22±1.63 to 30±1.63 minutes. The moisture content ranged from 4.95% to 13.40%. The study successfully developed and optimized fast-dissolving oral thin films for migraine management, demonstrating uniform thickness,

ISBN: 978-81-980623-8-3

neutral surface pH, and acceptable moisture content. These findings suggest that FDOTFs can provide a promising alternative for quick drug delivery and improved patient compliance.

**Keywords:** Migraine, fast dissolving oral thin film, Acute migraine therapy, Solvent casting method

rutikanandurkar18@gmail.com

Clarithromycin is a key antibiotic used in the treatment of Helicobacter pylori infection, but its poor solubility, instability in gastric conditions, and limited bioavailability restrict its therapeutic effectiveness. Formulating a gastroretentive self-emulsifying drug delivery system (SEDDS) offers a strategy to overcome these limitations by enhancing solubility, prolonging gastric residence, and improving drug release. The study aimed to formulate, develop, and evaluate a gastroretentive SEDDS of clarithromycin to improve its solubility, stability, gastric retention, and therapeutic efficacy in the management of H. pylori infection. The SEDDS mixture was prepared by adding appropriate quantities of oil, surfactant, and co-surfactant with the drug, the mixture was homogenized for uniform mixing. The optimized SEDDS exhibited a droplet size of 59.33 nm, zeta potential of –27.3 mV, and spherical droplet morphology confirmed by TEM. In-vitro drug release reached 96.45 ± 0.24% in 145 minutes. The solidified gastroretentive tablets (Batch F7) showed good flow properties, high mucoadhesive strength (25.5 g), prolonged gastric residence time (7.5 h), and sustained drug release (89.6% over 12 h). The formulated gastroretentive SEDDS tablets of clarithromycin successfully enhanced solubility, stability, gastric retention, and sustained release, thereby improving bioavailability and therapeutic potential against H. pylori infection.

**Keywords:** Clarithromycin, Gastroretentive drug delivery, Self-emulsifying drug delivery system (SEDDS), Helicobacter pylori, Mucoadhesion

Shwetadhongade748@gmail.com

Hyperlipidemia is characterized by elevated lipid levels, which are a significant risk factor for cardiovascular disease. The present study aimed to develop and evaluate a cubosomal nanodrug delivery system for the co-administration of Rosuvastatin and Fenofibrate for the treatment of hyperlipidemia. These drugs face limitations of poor solubility, rapid metabolism, and low bioavailability, which the cubosomal system seeks to overcome. Cubosomes were formulated using glyceryl monooleate as the lipid matrix and Poloxamer 407 as the stabilizer through a top-down homogenization technique. Formulations were optimized by Design Expert software, targeting particle size and entrapment efficiency. The characterized cubosomes exhibited a particle size of 119.4 nm with a positive zeta potential of +43.6 mV, indicating good stability, and demonstrated sustained drug release in vitro. Entrapment efficiencies were 93% for Rosuvastatin and 95% for Fenofibrate. In vivo pharmacodynamic studies in hyperlipidemic rats revealed a significant reduction of total cholesterol, triglycerides, LDL, and VLDL levels with a concomitant increase in HDL, outperforming conventional drug formulations. Specifically, treated rats showed near normalization of lipid profiles: total cholesterol reduced to 78.33 mg/dL, triglycerides to 91.33 mg/dL, LDL to 27.40 mg/dL, VLDL to 18.27 mg/dL, and HDL increased to 31.7 mg/dL. Histopathological examination confirmed safety and improved liver architecture. This study highlights the potential of cubosomal delivery systems to enhance the bioavailability and therapeutic efficacy of antihyperlipidemic drugs, offering a promising platform for improved management of hyperlipidemia.

**Keywords:** Cubosomes, Rosuvastatin, Fenofibrate, Antihyperlipidemic, Nanodrug Delivery.

**DEVELOPMENT OF RESVERATROL LIPOSOMES: A NANOCARRIER APPROACH FOR SENOSTATIC ACTIVITY**

Apoorva Ghate, Madhuri Madavi, Jayashree Taksande, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur (MH) – 442001
apoorvaghate1612@gmail.com

Aging is a multifactorial biological process associated with the progressive decline of physiological systems and an increased risk of chronic diseases such as cancer, cardiovascular disorders, diabetes, and neurodegenerative conditions. A major contributor is cellular senescence, a stress-induced state of permanent growth arrest that promotes tissue dysfunction through the senescence-associated secretory phenotype (SASP). Resveratrol, a natural polyphenol found in grapes, berries, and red wine, exhibits strong antioxidant, anti-inflammatory, cardioprotective, and neuroprotective properties. However, its therapeutic potential is limited due to poor solubility, low bioavailability, rapid metabolism, and instability. This study aims to develop and characterize resveratrol-loaded liposomes as biocompatible nanocarriers to enhance solubility, stability, and delivery efficiency, and to evaluate their potential as senostatic nanotherapeutics. Resveratrol was determined to be ethanol soluble with a melting point of 253°C, and drug-excipient compatibility was established using FTIR analysis. Optimization using a Box-Behnken Design resulted in an optimized liposomal formulation (F6) of particle size 0.522 µm. Zeta potential was also increased from 30.9 mV (uncoated) to -64.3 mV (coated), reflecting higher stability. Entrapment efficiency was also enhanced by the coating. In vitro release studies showed sustained release of Resveratrol from liposomes, with the chitosan-coated formulation showing slow and controlled release for 6 hours. The DPPH assay proved significant dose-dependent antioxidant activity of Resveratrol. In conclusion, the use of liposomal encapsulation with chitosan coating is a valid method to increase the oral delivery, stability, and therapeutic efficiency of Resveratrol, a potential anti-aging treatment.

**Keywords:** Resveratrol, aging, senostatic activity, oral delivery, liposomes, chitosan coating.

**PC-514**

**FORMULATION AND EVALUATION OF MUCOADHESIVE NANOPARTICLES OF VENLAFAXINE AND ARIPIPRAZOLE FOR TREATMENT RESISTANT DEPRESSION**

Divya Umathe, Yogesh S, Jayashree Taksande, Dinesh Biyani, Milind Umekar
Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India-441002
divyaumathe2002@gmail.com

Treatment-resistant depression presents a significant clinical challenge due to the limited efficacy of conventional oral antidepressants, often hindered by poor brain bioavailability and systemic side effects. This study explores the development of mucoadhesive nanoparticles as a novel intranasal delivery system aimed at enhancing therapeutic outcomes in TRD. The objective behind the research was to formulate and evaluate a nasal, mucoadhesive nanoparticle-based drug delivery system aimed at enhancing brain-targeted delivery of antidepressant agents for treatment-resistant depression (TRD). The mucoadhesive nanoparticles were prepared by ionic gelation method using chitosan as mucoadhesive polymer and sodium tripolyphosphate (STPP) as cross-linking agent and evaluated for relevant parameters like mucoadhesion, entrapment efficiency, release kinetics. Particle size of prepared nanoparticles were found to be 189±1.08nm which is suitable for nasal administration. Entrapment efficiency of VNLF was found to be 58±0.83% to 76±1.24% and ARP was 70±0.89% to 85±1.0%. The DSC analysis of VNLF-ARP nanoparticles showed disappearance of sharp endothermic peak of crystalline drugs and were replaced by broad transition between 178 to 202°C with reduced enthalpy values, it represents both the drugs were transformed into an amorphous state.

ISBN: 978-81-980623-8-3

In vitro release of VNLF-ARP nanoparticles showed VNLF exhibited faster drug release as compared to ARP. The ex-vivo drug release found that drugs release from both drugs increases with time interval. These findings suggested that chitosan-based mucoadhesive nanoparticles offer a promising intranasal delivery approach for enhancing brain-targeted drug delivery in treatment-resistant depression, potentially improving therapeutic efficacy while minimizing systemic side effects.

**Keywords:** Treatment Resistant Depression, nanoparticles, ionic gelation method, chitosan, sodium tripolyphosphate, Venlafaxine, Aripiprazole, blood brain barrier, mucoadhesion

## FORMULATION AND EVALUATION OF TRANSDERMAL PATCH OF SILDENAFIL CITRATE

Satheeshkumar. P1, Sriram M.2, Nithyapriya K.3, B. Sangameswaran4
srirammunusamy280@gmil.com

The objective of this study was to formulate and evaluate a transdermal patch of sildenafil citrate to enhance its bioavailability, reduce first-pass metabolism, and provide sustained release. Sildenafil citrate, a phosphodiesterase type 5 inhibitor, is commonly used in the treatment of erectile dysfunction but faces limitations related to its oral bioavailability and short half-life. Transdermal drug delivery offers an alternative route of administration that can bypass the gastrointestinal tract and liver metabolism, thereby improving therapeutic outcomes. The sildenafil citrate patches were prepared using different polymers hydroxypropyl methylcellulose, and plasticizers polyethylene glycol to optimize the release characteristics. The patches were evaluated for various physiochemical properties, including thickness, weight uniformity and drug content. In vitro drug release studies were conducted using a Franz diffusion cell to determine the release profile of sildenafil citrate. The result showed that the patches exhibited a controlled release over 24 hours, with a significant increase in drug permeation across the skin compared to conventional oral formulations. The stability studies indicated that the patches were stable under accelerated conditions, with no significant degradation of sildenafil citrate. The formulation demonstrated potential for effective transdermal delivery, providing a novel approach for sustained release sildenafil therapy, which could improve patient compliance and therapeutic efficacy.

**Keywords:** Sildenafil citrate, Hydroxypropyl, Phosphodiesterase

**PC-516**

## ENHANCEMENT OF SOLUBILITY OF BCS CLASS II DRUG BY USING SELF-NANO EMULSIFYING DRUG DELIVERY SYSTEMS

P.R. Sravyasri A. Lakshmi Usha, R. Sailaja
Department of Pharmaceutical Technology, Raghu College of Pharmacy, Visakhapatnam, A.P., India.
sravyasri531@gmail.com

The current research focuses on enhancing the solubility of Itraconazole (ITZ) by formulating a Nanoemulsion drug delivery system i.e. Self Nano Emulsifying Drug Delivery Systems(SNEDDS). Excipient selection for the SNEDDS formulation, including oils, surfactants, and co-surfactants, was based on drug solubility and emulsification efficiency. The Saturation Solubility of the Itraconazole was evaluated in various fixed oils such as Peppermint oil, Cinnamon oil etc using Shake Flask Method. Among the various oils tested, cinnamon oil has shown better solubility when compared to the other oils. Among the different surfactants and co-surfactants tested for solubility, highest solubility was reported in Tween 20 followed by Tween 60 (surfactants) tested and polyethylene glycol followed by propylene glycol (co-surfactants). To optimize the formulation, the study focused on variables such as particle size (nm), self-emulsification time (seconds), and percentage drug release. Ternary software was used to generate 3D response surface plots for analysis. The final L-SNEDDS formulations were assessed for particle size and zeta potential. The optimized L-SNEDDS formulation significantly improved Itraconazole (ITZ) solubility compared to the pure drug. The characterization of the L-SNEDDS revealed a particle size of 192.2 ± 2.41 nm, a self-emulsification time of 24 ± 2 seconds, and a cumulative drug release of 86.73 ± 1.57% in 60 minutes. Optimization of L-SNEDDS revealed enhanced solubility of Itraconazole by reducing the Particle size, demonstrating the potential of this formulation approach for improving drug solubility.

**Keywords:** Solubility, Itraconazole, SNEDDS, Co-surfactant.

## IN SILICO, IN VITRO, AND IN VIVO ASSESSMENT OF TERPENE COMPOUND NANOEMULSION AS A NOVEL THERAPEUTIC AGENT AGAINST BREAST CANCER

Mortha Lakshmi Prasanna
VJ's College of Pharmacy, Diwancheruvu, Rajahmundry, Andhra Pradesh, India – 533296
prasannavjs99@gmail.com

This study explores the antitumor properties of 2-carene, a terpene compound, and its nanoemulsion formulation against breast cancer models. We employed a multi-faceted approach, including in silico and molecular dynamic simulation studies, to assess the anticancer activity of 2-carene against breast cancer receptors. The nanoemulsion was prepared using a monoterpenoid compound isolated from Catharanthus roseus essential oil and characterized using various techniques, including scanning electron microscopy, Fourier transform infrared spectroscopy, and dynamic light scattering. Our results showed that the nanoemulsion exhibited significant cytotoxicity (54.31%) against MDA-MB-231 cancer cell lines and induced apoptosis in DMBA-induced breast cancer models. Furthermore, the nanoemulsion treatment improved antioxidant enzyme levels and reduced serum inflammatory markers. Histopathological evaluation revealed notable improvements in cancer-induced tissue damage. Overall, our findings demonstrate the promising anticancer potential of 2-carene and its nanoemulsion formulation, warranting further investigation into their therapeutic applications.

**Keywords:** 2-carene, nanoemulsion, MDA-MB-231 cell line, DMBA-induced model.

## FORMULATION AND EVALUATION OF ACACIA NILOTICA FRUIT TABLETS FOR ITS ANTI-ARTHRITIC POTENTIAL: A SCIENTIFIC VALIDATION OF TRADITIONAL USE

Tushar Kullarkar, Pavan Khodke, Kamala Chandak, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Maharashtra 441002
tusharkularkar90@gmail.com

Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterized by joint inflammation and disability. Although conventional therapies such as NSAIDs and DMARDs provide symptomatic relief, their long-term use is associated with adverse effects, highlighting the need for safer alternatives. The present study aimed to formulate and evaluate herbal tablets of Acacia nilotica fruits to scientifically validate their traditional use. The fruit powder was standardized as per WHO guidelines, and phytochemical screening confirmed the presence of flavonoids, tannins, and glycosides. In vivo evaluation using the Complete Freund's Adjuvant-induced arthritis model demonstrated a significant reduction in paw oedema and joint swelling, along with improvement in haematological parameters. Cytokine analysis further revealed decreased TNF-α and IL-6 and elevated IL-10 levels, confirming strong anti-inflammatory and immunomodulatory effects. Tablets prepared with suitable excipients complied with pharmacopeial quality standards and were found safe in acute toxicity studies. These findings establish Acacia nilotica fruits as a promising, safe, and economical alternative for the management of rheumatoid arthritis.

**Keywords:** Acacia nilotica, rheumatoid arthritis, herbal tablets, anti-inflammatory, cytokines.

Chewable tablets have an advantage over conventional tablets as well as liquid dosage forms in geriatric and pediatric patients as well as pregnant

ISBN: 978-81-980623-8-3

women to prevent morning sickness. They enhance both the therapeutic efficacy and the bioavailability. Domperidone chewable tablets were formulated so that compliance in the drug in children is achieved by improving the solubility and dissolution. Domperidone chewable tablets were prepared by employing wet granulation. Examination of the tablets was undertaken about general appearance, size, shape, color, odor, taste, hardness, friability, weight variation, disintegration, and content uniformity. The key is dissolution testing to discover the percentage of drug released and in the developed formulation. Mechanism of action and some tablet- making defects, for example capping, lamination, picking, sticking, and mottling, are discussed under the root cause of the problems. Examples of some chipped or edged product forms are antacids, aspirin for kids, and chewable vitamins.

**Keywords:** Domperidone chewable tablets, pediatric patients, liquid dosage.

Microspheres are versatile carriers in controlled drug delivery systems, capable of improving bioavailability, ensuring site-specific delivery, and reducing adverse effects. The incorporation of biodegradable polymers, such as sodium alginate and chitosan, enables safe and efficient sustained release formulations with improved patient compliance. Etoricoxib, a selective COX-2 inhibitor with poor aqueous solubility and gastrointestinal side effects when administered conventionally, was selected for formulation into microspheres to enhance its therapeutic efficacy and bioavailability. The present study aimed to formulate and evaluate Etoricoxib-loaded microspheres using the ionic gelation method. Sodium alginate and chitosan served as drug carriers, while calcium chloride acted as the cross-linking agent. The prepared microspheres were evaluated for particle size, entrapment efficiency, swelling index, in-vitro drug release, and stability. Preformulation studies confirmed the drug's compliance with Indian Pharmacopoeia standards. Among the formulated batches, the optimized formulation (F4) demonstrated favorable physicochemical properties, including uniform and spherical particle size distribution, high drug entrapment efficiency, and excellent swelling behavior. In-vitro release studies revealed sustained drug release, with formulation F4 achieving 97.20% cumulative release within 8 hours, aligning with the desired controlled release profile. Stability testing under accelerated conditions (40 °C) exhibited no significant drug degradation, indicating good formulation stability. In conclusion, Etoricoxib microspheres prepared by ionic gelation using sodium alginate and chitosan represent a promising controlled drug delivery system. This formulation offers sustained release with improved therapeutic efficacy, reduced dosing frequency, minimized side effects, and enhanced patient compliance.

**Keywords:** Microspheres, Etoricoxib, Sodium Alginate, Chitosan, Controlled Drug Delivery

Nanosponges are drug delivery system containing of nano sized sponges build in with active drug constituents. Newly this technology has progressive management of many diseases which involve targeted delivery. The current study fascinated on the development of a novel strategy to enhance the bioavailability of resveratrol, due to its dissolution rate-limited absorption, though it is a class II drug, results in poor oral bioavailability. Nanosponges were statistically developed by full 33 factorial design using Design of Experiment 13.0 software considering concentration of polymer, stabilizer and stirring time as independent variables and particle size, % entrapment efficiency and percentage yield as experimental responses by utilizing the modified Emulsion solvent diffusion technique. Drug polymer compatibility study was performed by FTIR and DSC. Optimized formulation showed 92.34 Percentage yield, 92.5 % entrapment efficiency, 181.4 nm particle size and –33.7 mV of zeta potential and % Drug release. The data from in vitro release study showed burst release for initial 2 h followed by slow and sustained release up to 12 hours, which followed a diffusion-controlled release mechanism by the Higuchi model. Scanning electron microscopy study showed uniformly discrete spherical particles with porous surface without any agglomeration. Stability study demonstrated no significant changes in particle size, entrapment efficiency and in vitro release, which indicated that the nanosponge formulation was stable.

**Keywords:** Resveratrol Nanosponge, , Full 33 factorial design, invitro drug release, Higuchi model, targeted delivery.

snehajawale1997@gmail.com

Hydrochlorothiazide (HCTZ), a commonly prescribed thiazide diuretic, exhibits poor water solubility and low intestinal permeability, limiting its oral bioavailability. This study aimed to enhance the physicochemical and biopharmaceutical properties of HCTZ by formulating nanocrystals using various stabilizers—HPMCAS, HPMC E5, HPMC K100M CR, Kollidon 30, Kollidon VA 64, and Poloxamer 108—via the antisolvent precipitation method. The resulting nanocrystals were characterized for particle size, zeta potential, drug content, solubility, crystallinity, and morphology using standard analytical techniques (FTIR, PXRD, DSC, SEM, and 13C SSNMR). In vitro dissolution and permeability studies, along with short term stability assessments, were conducted. HPMCAS-stabilized nanocrystals demonstrated the smallest particle size (212.1 nm) and the most negative zeta potential (−29.6 mV), indicating excellent stability. Kollidon VA 64 significantly enhanced saturation solubility (~20 fold), while Kollidon 30 showed superior dissolution in both acidic and phosphate media. Enhanced permeability was observed with HPMC E5 and Kollidon VA 64 in simulated gastric and intestinal fluids, respectively. Stability studies revealed that formulations with HPMCAS and Poloxamer 108 maintained their physicochemical properties under stress conditions. Overall, the study highlights the critical role of stabilizer selection in developing effective nanocrystal formulations to improve the solubility and bioavailability of poorly soluble drugs like HCTZ.

**Keywords:** Hydrochlorothiazide, Solubility, Dissolution, Permeability, Nanocrystals

**DEVELOPMENT AND ASSESSMENT OF AN IN-SITU GEL BASED ON CARBOXYMETHYL TAMARIND GUM FOR OCULAR DRUG ADMINISTRATION**

Yogyata S Pathare, Manoj S Tare, Mrunal R Kale
Department of Pharmaceutics, STES's Sinhgad College of Pharmacy affiliated to Savitribai Phule Pune University, Pune 411041
yogyataspathare@gmail.com

Ocular bioavailability remains a challenge in ophthalmic drug delivery. The use of an in-situ gel-forming system, which is administered as a drop into the eye and undergoes a sol-gel transition in the cul-de-sac, may be used to overcome the poor bioavailability and therapeutic response displayed by conventional ophthalmic solutions due to rapid precorneal elimination of the drug. In the present research work, efforts were made to prepare the sustained release in situ gel containing Moxifloxacin Hydrochloride using polymers such as gellan gum, CMTG, and sodium Alginate for the treatment of ocular infections. The prepared in situ gel formulations were evaluated for In vitro gelation time, clarity, pH

ISBN: 978-81-980623-8-3

measurement, gelling capacity, drug content estimation, rheological study, in vitro release study, antimicrobial study & mucoadhesion study. In the in vitro results it was observed that the percentage release of the drug from the developed formulations F5(99.5%), F6 (97.18%), F9 (95.57%), Formulation F5 showed more sustained release compared to other formulations and showed the desired zone of inhibition values against staphylococcus aureus. The optimized formulation of in situ gel was stable and provided sustained release of drug within a period of 24 h. It is thus concluded that developed formulation is a viable alternative to conventional eye drops by virtue of its ability to enhance bioavailability through its longer precorneal residence time and ability to sustain drug release.

**Keywords:** ocular drug delivery, In situ gel, CMTG, gellan gum

**LIPOSOMAL LOADED TOPICAL FORMULATION FOR SKIN REJUVENATION THERAPY**

Varsha T, Mohammed Haneefa KP, Suryanarayanan.J
Department of pharmaceutics, Moulana College of Pharmacy, Perithalmanna, Kerala, India, 679322

Liposomes are one of the most commonly used nanocarrier, due to active transport of hydrophilic & lipophilic drugs effectively. This study explores the development and assessment of a liposome-loaded topical formulation designed for skin rejuvenation therapy. Liposomes containing glutathione, a potent antioxidant, were prepared using dried thin film hydration method, encapsulating it within a bilayer composed of soya lecithin and cholesterol. This liposome were integrated into carbopol based gel matrix to produce a liposome loaded topical formulation for external application on skin. Liposome were prepared in 6 batch using different concentration of soya lecithin and cholesterol while the amount of drug glutathione is same. The research evaluated the formulation's physical properties, pH, viscosity, spreadability, invitro permeation, and stability across varied conditions & also evaluate the particle size and zeta potential for liposomal conformation. The result showed that the liposomal gel exhibited smoothness, uniformity, and a pH level compatible with skin's natural balance, facilitating enhanced permeation of glutathione through the skin for all formulations. The formulation demonstrated robust stability, maintaining its chemical and physical characteristics under diverse storage conditions. But formulation 3 shows better stability and entrapments compare to others. These findings suggest that the developed liposome-loaded topical formulation shows potential for effective skin rejuvenation therapy, necessitating further investigation and clinical validation.

**Keywords:** Liposomes, Skin Rejuvenation, Glutathione, Topical Formulation, Stability Studies.

**CONTINUOUS MANUFACTURING OF AN NSAID OLEOGEL VIA TWIN-SCREW PROCESSING: FORMULATION DEVELOPMENT AND PERFORMANCE EVALUATION**

Naitik Jain, Srinivas Mutalik
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal 576104, Karnataka, India
naitikjain30@gmail.com

This study developed and optimized a topical diclofenac sodium oleogel using twin-screw processing (TSP), a continuous manufacturing technology that enables scalable and reproducible production. A Box–Behnken Design was employed to optimize key processing parameters and lecithin concentration. The oleogel was characterized for yield, texture, viscosity, spreadability, pH, drug content, and in vitro release, with structural analysis confirming amorphous drug dispersion and excipient compatibility. The optimized formulation (DOE-TSP-O) exhibited uniform physical properties, high drug loading, and sustained release without causing skin irritation. In vivo studies demonstrated significantly enhanced permeation, analgesic, and anti-inflammatory effects compared to conventional hydrogels, along with marked suppression of TNF-α, IL-6, and NFκB p65 expression. The formulation also maintained stability for over three months under long-term storage conditions. Overall, DOE-TSP-O represents a promising next-generation topical therapy for pain and inflammation, combining superior efficacy and stability with the manufacturing advantages of TSP.

**Keywords:** Continuous manufacturing, Twin screw processor, NSAIDs, Topical delivery

**PC-526**

**DEVELOPMENT AND CHARACTERIZATION OF POLYSACCHARIDE BASED NATURAL HYDROGEL FOR ENHANCED SKIN PROTECTION**

Sreeshma M, Ameena. K
Department of pharmaceutics, Moulana college of pharmacy, Perinthalmanna, Kerala India 679322

A hydrogel is a three-dimensional network of hydrophilic (water-attracting) polymers that can absorb and retain large amounts of water while maintaining their structural integrity. This study presents the development of a novel skin protectant gel formulated with a hydrogel matrix reinforced by nanocellulose derived from banana peels through sulfuric acid treatment and by pectin derived from sweet lemon and guava via simple extraction method. The cellulose extracted from banana peels is transformed into nano-cellulose via controlled acid hydrolysis. Phytochemical screening of herbal extracts were carried out for tannins, saponins etc . Physico chemical characterizations like determination of pH , loss on drying etc are carried out . Research evaluated the formulations physical appearance, extrudability, homogeneity, PH, skin irritation, smoothness, spreadability, stability studies, stickiness, viscosity, washability. Results indicate that the formulation with smooth in texture, homogenous, identical PH of the skin, good washability, non -irritant, and the formulations show dose dependant antibacterial efficacy. Polysaccharide based natural hydrogels are emerging as effective materials for skin protection due to their bio compatibility, moisture retention properties and bioactivity. The findings offer that the polysaccharide based natural hydrogel containing banana peel extract, guava fruit extract, sweet lemon peel extract, turmeric, and aloe vera shows great potential for antiaging and skin rejuvenation, personalized skin protection and further clinical studies and research.

**Keywords:** polysaccharide, skin protection, hydrogel, antimicrobial activity

**PC-527**

**PREPARATION AND EVALUATION OF PHYTOSOMES FOR– A COMBINATIONAL APPROACH OF CURCUMIN AND GREEN TEA EXTRACT**

NAVYA AN

Phytosomes is a novel technique introduced by Indena that combines a standardized herbal extract and phospholipid in a preferably equal ratio to provide better absorption and enhancing bioavailability. The objective of the proposed study is to prepare, optimize, and characterize phytosomes of Curcumin and Green tea extract. The solvent evaporation method was used to prepare phytosomes. Design Expert software version 12 was used to evaluate the impact of soya lecithin concentration, Stirring time, and Stirring Speed on various dependent variables, such as particle size and entrapment efficiency. The evaluation parameters were % practical yield, FTIR, entrapment efficacy, DSC, particle size, Drug Content, SEM, and In-vitro release studies. The phytosomes were successfully designed and optimized for particle size, and entrapment efficiency of 296.01 nm, 90.76% of curcumin, and 87.0121% of green tea extract, respectively. Scanning electron microscopy demonstrated predominantly slightly spherical shapes. The yield varied from 77.21±0.12 to 94.61% and the drug content of 95.83 ± 0.17% for curcumin and 91.54 ± 0.45% for green tea extract. It was observed that the formulation showed an optimum release of 96.1% for curcumin and 94.2% for green tea extract over a period of 8hours. The study successfully developed and optimized phytosomes of curcumin and green tea extract with high entrapment efficacy, desired particle size, and improved in vitro release profiles. These results suggest that phytosomes formulation can significantly enhance the bioavailability and controlled release of herbal extracts.

**PC-528**

**Standardization, Evaluation And In-Silico Studies Of Three Bioactive Natural Colouring Agents**

Yuvaraj. K, Nanthakumar.A, S. Asuran, Madhu.C. Divakar

Colour is considered to be the primary feature perceived by the senses that represent a crucial role for centuries in the acceptability of foods to enhance their actual appearance and quality. Plant pigments, the

ISBN: 978-81-980623-8-3

impeccable natural source of colour, display enormous potential to substitute many of the synthetic colorants. Chlorophylls, carotenoids, anthocyanins, and betalains are the extensive classes of natural colours contributing wide-ranging colour shades to foods. There are good perspectives for the inclusion of plant pigments in the food industry. Natural dyes are less toxic, less polluting, non-carcinogenic and non-poisonous. The work focusses on, an ecofriendly and cost-effective extraction of three natural colorants obtained from Caesalpinia sappan, Clitoria ternatea and Selenicereus undatus which can be used as pharmaceutical excipients, food colorants, and cosmetics, etc. Apart from that the natural color itself has its own therapeutic activity therefore, the rational use of these colors along with the synthetic drugs will impart not only the coloring effect for the formulation but it can make an additive effect along with the therapeutic action of the drug. HPTLC evaluation of these colour extracts indicated the presence of the reference standard quercetin in Clitoria flower and Sappan wood extracts as 87.68 mcg/mg and 72.64 mcg/mg respectively. The amount of reference standard gallic acid in dragon fruit extract is found to be 38.46 mcg/mg. The colour extracts CSWC (C. sappan wood color extract), CTFC (C. ternatea flower colour extract) and SUFC (S. undatus fruit colour extract) showed an LC50 value of 7943.3, 6534.5 and 5623.4 mcg/ml respectively as compared with FCF color 15985,14720 (3981.07mcg/ml), Brilliant blue FCF (3771.7mcg/ml), Carmoisine (1989.57 mcg/ml) respectively in the brine shrimp lethality assay method (BSLA). The percentage yield obtained for CSWC, CTFC, and SUFC are 90.5, 94.25 and 95.35 respectively. In-silico molecular docking studies revealed that quercetin present in CSWC, CTFC and gallic acid present in SUFC showed significant binding affinity against COX-2, DPP-4 and SOD respectively.

**Keywords:** CSWC, CTFC, SUFC, HPTLC, In-silico docking COX-2, DPP-4, SOD, BSLA

**Development And Characterization Of Emulgels Containing Andrographolide For Improved Dermal Delivery Against Epidermoid Cancer**

N V L Sirisha Mulukuri, Pankaj Kumar, N.V. Satheesh Madhav, Kusum Devi
Department of Pharmacognosy, Nitte College of Pharmaceutical Sciences (A constituent unit of Nitte Education Trust), Bengaluru-560064, India.
Sirisha.mulukuri@nitte.edu.in

The present study aimed to develop and evaluate nano-sized andrographolide-loaded glycerogels for their potential application in skin cancer therapy with improved permeation. Nano-sizing of andrographolide was achieved through sonication followed by solvent evaporation, and the optimized formulation was subjected to comprehensive physicochemical evaluations, release kinetics, particle size analysis, ex-vivo permeation studies, biocompatibility tests, cytotoxicity assays against A431 cell lines, cell cycle analysis, skin irritability assessments, and in-vivo cellular uptake studies. The optimized nano-emulgel exhibited in-vitro drug release of 92.5 ± 0.5% following Higuchi kinetics, while ex-vivo permeation studies demonstrated approximately 90% drug release within 24 hours, with 10% retention in the epidermal layer, confirming superior skin permeation and retention properties. Overall, the enhanced permeability and retention along with histopathological studies observed with nano-glycerogel formulations of andrographolide suggest a promising novel phytotherapeutic approach for the treatment of skin cancer.

**PC-530**

**FORMULATION AND EVALUATION OF ROSUVASTATIN PEGYLATED SOLID LIPID NANOPARTICLES USING BOX BHENKEN DESIGN - A PRELIMINARY IN-VITRO STUDY**

ROOPASHREE B

Hypercholesterolemia is a major cause of cardiovascular diseases, demanding effective therapeutic interventions. Rosuvastatin, a potent HMG-CoA reductase inhibitor, is widely prescribed but suffers from poor aqueous solubility and low oral bioavailability. Nanocarrier-based systems such as solid lipid nanoparticles (SLNs) can overcome these limitations by enhancing solubility, stability, and controlled release. Further, PEGylation prolongs systemic circulation and minimizes immune clearance, improving therapeutic efficiency. This study aimed to develop and optimize rosuvastatin-loaded PEGylated SLNs (PEG-SLNs) using a Box–Behnken design (BBD). SLNs were prepared by solvent evaporation and modified with PEG-2000. The influence of lipid, surfactant, and Phospholipid concentrations on particle size and entrapment efficiency was systematically analyzed. Optimized PEG-SLNs showed an average size of ~301 nm with entrapment efficiency above 95%. SEM confirmed spherical morphology with smooth surfaces, while ATR-FTIR and DSC analyses verified drug–excipient compatibility. In-vitro diffusion studies demonstrated sustained release, with PEG-SLNs achieving 96.54% cumulative release over 8 hours versus 87.24% for plain SLNs. Drug release followed Zero-order and Higuchi models, indicating a non-Fickian diffusion mechanism. PEGylation improved encapsulation, release control, and circulation stability, making PEG-SLNs superior to conventional SLNs. Rosuvastatin-loaded PEG-SLNs were successfully formulated and optimized using BBD, yielding stable nanoparticles with high entrapment efficiency and sustained release. PEGylation enhanced drug delivery properties and prolonged circulation, offering a promising strategy to improve rosuvastatin bioavailability and therapeutic performance in hypercholesterolemia management.

**Keywords:** Solid lipid nanoparticles, PEGylation, Hypercholesterolemia, Rosuvastatin, Sustained release, Box–Behnken design.

**PC-531**

**DESIGN, DEVELOPMENT AND EVALUATION OF COMBINATORIAL DRUG (DICLOFENAC SODIUM AND CURCUMIN) LOADED COLLOIDOSOME**

HEMANTH V

Colloidosomes are hollow microcapsules formed by the self-assembly of colloidal particles at liquid interfaces, offering exceptional mechanical stability, tunable shell permeability, and multi-drug loading capacity. This study aimed to design alginate–$CaCO_3$ colloidosomes capable of co-delivering diclofenac sodium and curcumin, targeting sustained anti-inflammatory therapy through a single delivery system. Colloidosomes were fabricated via a water-in-oil emulsification technique using virgin coconut oil as the continuous phase, sodium alginate as the polymeric shell, and $CaCO_3$ microparticles as stabilizers. Diclofenac sodium and curcumin were incorporated in a methanolic solution before gradual addition of the aqueous alginate phase. The prepared systems were characterized for morphology, particle size, encapsulation efficiency, drug content, thermal compatibility (DSC), and in-vitro release kinetics. The formulation yielded spherical colloidosomes with narrow particle size distribution and high encapsulation efficiencies for both drugs. DSC thermograms confirmed molecular dispersion of the drugs without any incompatibility. In-vitro release profiles revealed a controlled and sustained release over 8 h, with cumulative releases of ~96% for diclofenac sodium and ~94% for curcumin, fitting predominantly zero-order kinetics—indicating constant drug release independent of concentration. The dual-drug-loaded alginate–$CaCO_3$ colloidosomes successfully integrated hydrophilic and hydrophobic agents into a stable, controlled-release platform. These findings establish the potential of such colloidosomes as an efficient and versatile delivery vehicle for combination therapy in inflammatory disorders, warranting further in-vivo investigation.

**Keywords:** colloidosomes, alginate–$CaCO_3$, diclofenac sodium, curcumin, dual drug delivery, sustained release

**PC-532**

**DEVELOPMENT AND COMPARATIVE EVALUATION OF ASPIRIN LOADED PHARMACOSOMES BY SOLVENT EVAPORATION AND ETHER INJECTION METHODS**

PUNITHA G

Pharmacosomes represent an innovative drug delivery system in which drug molecules are chemically linked to phospholipids. This approach enhances drug solubility, bioavailability, and stability, while minimizing drug leakage. Aspirin, a widely used non-steroidal anti-inflammatory drug (NSAID), faces challenges due to its poor water solubility and gastrointestinal side effects. Delivering aspirin via pharmacosomes may improve its therapeutic efficacy and reduce adverse effects. Aspirin-loaded pharmacosomes were prepared using two distinct techniques: solvent evaporation (SE) and ether injection (EI). Both methods were optimized employing a Central Composite Design (CCD) framework, focusing on lecithin concentration (ranging from 50 to 500 mg) and

ISBN: 978-81-980623-8-3

temperature (30 to 60 °C) as the independent variables. The key response variables evaluated were particle size (PS, nm) and encapsulation efficiency (EE, %). Characterization of the optimized formulations was performed using Differential Scanning Calorimetry (DSC), Fourier-Transform Infrared Spectroscopy (FTIR), Scanning Electron Microscopy (SEM), and in vitro drug release studies. Both preparation methods yielded nanosized pharmacosomes with particle sizes ranging from 109 to 147 nm and high encapsulation efficiencies between 88% and 98.6%. Lecithin concentration exerted a significant influence on particle size ($p < 0.05$), while temperature notably affected outcomes primarily in the SE method. The optimized formulation produced by solvent evaporation exhibited a particle size close to 128 nm, an encapsulation efficiency of 98.6%, and sustained drug release extending up to 12 hours, with a slightly higher cumulative release compared to the ether injection method. Structural and thermal analyses confirmed the formation of stable aspirin–phospholipid complexes without any evidence of drug degradation. Comparative evaluation demonstrated that the solvent evaporation technique produces smaller, more stable pharmacosomes with superior encapsulation efficiency and prolonged drug release relative to the ether injection method. Consequently, solvent evaporation appears to be a more promising approach for preparing aspirin pharmacosomes, potentially enhancing oral drug delivery and patient adherence.

**Keywords:** Pharmacosomes, aspirin, solvent evaporation, ether injection, encapsulation efficiency, drug delivery optimization.

**PC-533**

## EVALUATION OF SEMISOLID DOSAGE FORMS USING IVRT AND IVPT STUDY: A NOVEL APPROACH FOR OPTIMIZING TOPICAL FORMULATIONS

Vishwas Toke, Tanaji Nandgude
School of Pharmaceutical sciences, Faculty of Health Science, JSPM University,
Wagholi, Pune – 412207, Maharashtra, India
vishvastoke123@gmail.com

The development of semisolid dosage forms, such as creams, gels, and ointments, has become increasingly popular due to their ease of application, improved patient compliance, and targeted therapeutic effects. However, the evaluation of these formulations poses significant challenges due to their complex composition and variable release characteristics. Recent trends in pharmaceutical research have focused on the development of in vitro testing methods, including In Vitro Release Testing (IVRT) and In Vitro Permeation Testing (IVPT), to assess the performance of semisolid dosage forms.IVRT is a widely accepted method for evaluating the release of active pharmaceutical ingredients (APIs) from semisolid dosage forms, while IVPT is used to assess the permeation of APIs through biological membranes, such as skin.A recent study demonstrated the application of IVRT and IVPT to evaluate the release and permeation characteristics of a topical formulations.The study highlights the importance of using IVRT and IVPT in combination to provide a comprehensive understanding of the release and permeation characteristics of semisolid dosage forms. This approach enables the development of optimized formulations with improved therapeutic efficacy and reduced variability. Furthermore, the use of IVRT and IVPT can help to reduce the need for in vivo studies, accelerate the development process, and decrease the costs associated with the development of semisolid dosage forms.

**Keywords:** semisolid dosage forms, in vitro release testing, in vitro permeation testing, IVRT, IVPT, topical formulations, cream, gel, ointment, release characteristics, permeation characteristics.

## ENHANCED ANTIBACTERIAL ACTIVITY OF MEROPENEM METALLIC NANOPARTICLES AGAINST MDR MICROORGANISMS

Bharti Sakharkar, Monali Manghani, Neha Raut, Rashmi Trivedi
Department of Pharmaceutical Quality Assurance Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Maharashtra 441002
bhartisakharkar8@gmail.com

Antimicrobial resistance poses a serious threat to global health, urging innovative drug delivery approaches. This study focuses on the synthesis of metallic nanoparticles of Meropenem (Mero-M NPs) using probe sonication with silver (Ag), copper (Cu), and zinc (Zn) as metal ions. Characterization via UV-Vis spectroscopy confirmed the formation of Mero-M NPs by a shift in the absorption peak compared to Meropenem. FTIR spectroscopy revealed changes in the functional groups of the nanoparticles, further supporting their formation. XRD analysis indicated the crystalline nature of both Meropenem and the synthesized nanoparticles. FESEM images confirmed the presence of nanoparticles with varying shapes depending on the metal ion used. EDX analysis confirmed the elemental composition of the nanoparticles. Silver nanoparticles showed a size of 121 nm with moderate stability, while copper and zinc nanoparticles demonstrated improved zeta potential -25.8mV. Antibacterial studies against E. coli, K. pneumoniae, A. baumannii and S. aureus revealed that Mero-Ag NPs exhibited superior antibacterial activity compared to standard Meropenem and other formulations. Stability assessments (color, FTIR, particle size, and zeta potential) under various conditions confirmed nanoparticle integrity. Acute toxicity studies supported the safety of Mero-Ag NPs. These findings suggest that metallic nanoparticles, particularly those incorporating silver, can significantly enhance Meropenem's therapeutic efficacy against resistant pathogens.

**Keywords:** Antimicrobial resistance, Meropenem, metallic nanoparticles, antibacterial, silver, probe sonication.

## FORMULATION AND DEVELOPMENT OF ORAL DOSAGE FORM OF PANCHGAVYA GHRITA FOR TREATMENT AND MANAGEMENT OF DIABETES MELLITUS

Harshad Patil, Ruchi Khobragade, Milind Umekar, Rashmi Trivedi.
Department of Pharmaceutical Quality Assurance, smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Nagpur- 441002.
harshadpatil5065@gmail.com

Panchgavya Ghrita (PGG), a classical Ayurvedic formulation composed of five cow-derived products, holds significant therapeutic value in chronic metabolic conditions, including diabetes mellitus. Despite its traditional efficacy, the lipidic and semi-solid nature of PGG poses challenges in terms of patient compliance, dose uniformity, and stability. This research aims to overcome these limitations by formulating PGG into a conventional oral tablet dosage form, ensuring better delivery, patient acceptability, and controlled dosing. The formulation process involved adsorbing the Ghrita onto optimized concentrations of Fujicalin® and Neusilin® to convert it into a free-flowing powder. Excipients including microcrystalline cellulose (MCC), hydroxypropyl methylcellulose (HPMC), and crospovidone were incorporated to improve compressibility, disintegration, and hardness. UV spectrophotometry was used to evaluate in vitro drug release, with the λ max established at 239 nm. This study successfully transformed a traditional lipid-based Ayurvedic formulation into a scientifically validated tablet dosage form. The developed PGG tablets may serve as a promising alternative in managing diabetes mellitus with improved patient compliance and reproducibility in clinical use.

**Keywords:** Panchgavya Ghrita (PGG), Diabetes Mellitus, Conventional Tablet, Fujicalin, Neusilin.

**PC-536**

## FORMULATION AND EVALUATION OF TRANSDERMAL PATCHES OF CORDIA DICHOTOMA: A MOLECULAR DOCKING APPROACH FOR ANTI-ARTHRITIC ACTIVITY

Akshada Walsinge , Yashwant Nakhate,
School Of Pharmacy, Gh Raison University Amravati, Maharashtra

This research explores the development and assessment of Cordia dichotoma transdermal patches for anti-arthritic potential through both experimental formulation and molecular docking validation. Ethanolic extracts of the plant were prepared and analyzed, revealing key phytochemicals including flavonoids (quercetin, rutin), phenolic compounds (gallic acid, ferulic acid), and alkaloids (cordifolamine derivatives). These extracts were incorporated into polymeric patches prepared via solvent casting, which exhibited desirable physicochemical attributes such as consistent thickness, folding endurance, appropriate moisture content, and sustained drug release. To further substantiate their therapeutic action, molecular docking was performed against rheumatoid arthritis targets—cyclooxygenase-2 (COX-2) and tumor necrosis factor-alpha (TNF-α). Docking studies indicated strong interactions, with quercetin showing binding scores of −9.1 kcal/mol

ISBN: 978-81-980623-8-3

(COX-2) and −8.7 kcal/mol (TNF-α), rutin −8.6 and −8.2 kcal/mol, gallic acid −7.9 and −7.4 kcal/mol, and ferulic acid −7.2 and −6.8 kcal/mol, respectively. These outcomes suggest that Cordia dichotoma phytoconstituents possess significant potential to modulate inflammatory pathways in arthritis. Overall, the work highlights that combining transdermal drug delivery with computational docking strengthens the case for Cordia dichotoma-based patches as a novel anti-arthritic therapy.

**Keywords:** Anti-Arthritic activity, Cordia Dichotoma, Phytoconstituents and Molecular Docking.

**PC-537**

## FORMULATION AND EVALUATION OF NANOGEL OF ACOROUS CALAMUS

Manjiree Ravindra Sonone , B.V. Nagarjuna Yadav
G.H. Raisoni University, School Of Pharmacy, Amravati, Maharashtra

Acorus calamus, commonly known as "sweet flag," contains aromatic oil with various medicinal properties such as antispasmodic, carminative, anthelmintic, and expectorant activities. The roots of A. calamus have shown strong analgesic effects, supporting its traditional use in pain treatment. This study aims to explore the anti-inflammatory activity of A. calamus and utilize nanogel as a drug delivery system to enhance the absorption of active compounds like monoterpenes, providing targeted and effective anti-inflammatory treatment. Investigating A. calamus' chemical composition and traditional uses contributes to natural product-based drug development. The biocompatible nature of A. calamus' nanogel ensures it does not cause skin irritation. Moreover, in vivo studies have shown that the anti-inflammatory activity of the A. calamus' nanogel is significantly higher compared to a standard diclofenac 1.0% gel with an equivalent concentration. This enhanced efficacy can be attributed to the ultra-small size of the nanoparticles present in the nanogel formulation. Based on the in vivo data, it can be concluded that the developed A. calamus' nanogel holds great potential for transdermal drug delivery. Its ability to deliver drugs through the skin could lead to improved therapeutic outcomes, as it offers a highly effective and targeted approach for the treatment of inflammatory conditions. The findings suggest that the A. calamus' nanogel could be a promising alternative to conventional topical formulations, providing a more efficient and potent means of drug administration.

**Keywords:** Acorus calamus, Nanogel, Anti-inflammatory activity and Analgesic effects.

**PC-538**

## FORMULATION AND EVALUATION OF HERBAL LIPSTICK OF BETA VULGARIS (BEETROOT) CONTAINING ANTIMICROBIAL AGENT

Yash Popte, Pratiksha Khajone, Rashmi Trivedi, Supriya Shidhaye ,Milind Umekar.
Department of Pharmaceutical Quality Assurance
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee Maharashtra 441002
popteyash@gmail.com

The growing demand for natural and safe cosmetic products has led to increased interest in herbal formulations. Among them, herbal lipsticks are emerging as a healthier alternative to conventional ones, which often use synthetic dyes and chemicals that may cause allergies or skin irritation. This study aimed to create and test an herbal lipstick using beetroot (Beta vulgaris) extract as a natural colorant, while also adding an antimicrobial component for extra therapeutic benefits. Beetroot, rich in betalains, provides a bright red shade along with antioxidant properties. To further protect against infections, ingredients like curcumin or fluconazole were included to help fight common bacterial and fungal issues affecting the lips. The lipstick was made with natural waxes (beeswax, carnauba wax, cocoa butter) and fixed oils (castor oil, and coconut oil) as natural base, chosen for their ability to give good texture, smooth application, and moisturization. The formulation was checked for different quality factors, including melting point, pH, hardness, spreadability, solubility, drug content, release behavior, skin absorption, and stability. Its antimicrobial potential was also tested, particularly against Candida albicans. The results showed that the beetroot-based lipstick had appealing appearance, good stability under storage, and promising antimicrobial activity. Overall, the study suggests that herbal lipsticks are made with natural colors, and antimicrobial agents can be safe, effective, and multifunctional cosmetic options with fewer side effects.

**Keywords:** Lipstick, Beetroot extract, antimicrobial agent, Candida albicans, Natural colorant.

**PC-539**

## FORMULATION AND EVALUATION OF AMIKACIN LOADED PLGA NANOPARTICLES BASED TRANSDERMAL PATCH FOR THE TREATMENT OF WOUND HEALING

Mrunal Dilip Kamble, Vaibhav Takare ,B.V. Nagarjuna Yadav
G.H. Raisoni University, School Of Pharmacy, Amravati, Maharashtra

Now a day many drugs are administered orally, but they are observed not more effective as desired so to upgrade such character TDDS was created. A transdermal dermal patch is characterized as a medicated adhesive patch which is set over the skin to deliver a particular dose of medication by the skin with a foreordained rate of release to reach into the circulation system. The purpose of the research work was to formulation and evaluation of nanoparticle loaded transdermal drug delivery system of Amikacin using polymers such as poly lactic coglycolic acid, hydroxy propyl methyl cellulose by the solvent evaporation method. The Fourier transform study revealed no physical or chemical reaction in between Amikacin, PLGA and HPMC. The differential scanning calorimetry study also confirms the sharp exothermic peak at melting point of drugs and polymers. the physical appearance also studied like physical evaluation, colour, odour, taste, solubility. The prepared nanoparticles were evaluated for Drug content, entrapment efficiency, PDI, particle size, zeta potential. On the basis of these parameter of nanoparticles the optimized batch were used to formulation of nanoparticle loaded transdermal patch. The prepared formulation was evaluated for different physiochemical characteristics such as, weight uniformity, thickness, folding endurance, flatness, surface pH determination, skin irritation, drug content, in-vitro drug release study. The result of in vitro drug release study F3 shows maximum release of 84.5% in 24 hrs. Whereas F2 shows the minimum release of 70.5% in 24 hrs. Based on that the physiochemical values and drug release and obtained the formulation F3 was considered as an optimized formulation, which shows the higher percentage of drug release of 84.5% in 24 hrs. The developed nanoparticle loaded transdermal patches increase the therapeutic efficacy and bioavailability of Amikacin.

**Keywords:** Skin, Wound, Amikacin, PLGA, HPMC And Transdermal Patch.

**PC-540**

## FORMULATION AND INVITRO EVALUATION OF CYTARABINE LOADED PLGA NANOPARTICLES WITH BIOENHANCER

Mohammed Saad, B.V. Nagarjuna Yadav
School Of Pharmacy, G.H. Raisoni University Amravati, Maharashtra

In order to lower total dosage needed for leukaemia therapy by loading in polymeric nanocarrier, this research study was conducted with goal of creating nanoparticles carrying Cytarabine HCl that have high stability and controlled release of Cytarabine HCl. To reduce the total dosage needed for chemotherapy in order to lessen the negative responses. Sustained delivery of the loaded medications to the appropriate location is possible with polymeric nanoparticles. Cytarabine HCl (CYTNP)-containing PLGA nanoparticles were formulated for continuous release during intravenous injection, which enhance patient compliance and lessen side effects. Using FT-IR, it was discovered that PLGA, had good compatibility with cytarabine and no mutual interaction. PLGA polymer and quercitin as bioenhancer were used in modified nanoprecipitation method to formulate CYTNP. Sustained delivery of the loaded medications to appropriate location is possible with polymeric nanoparticles. It is comfortable to utilize PLGA, a biodegradable polymer, to formulate nanoparticles. The particle size of prepared nanoparticles increased as percentage of polymer increased. Quercitn, a bioenhancer, is utilized to enhance activity, and entrapment efficiency and drug content were both found to rise. PLGA nanoparticles' surface morphology was analysed using transmission electron microscopy (TEM). According to the nanoformulation, the particles are round, smooth, and distinct.

**Keywords:** Nanoparticles, Cytarabine, Cancer, Nanoformulations and Blood Brain Barrier (BBB).

ISBN: 978-81-980623-8-3

**A NOVEL BUCCAL MUCOADHESIVE DRUG DELIVERY SYSTEM OF GLIPIZIDE: FORMULATION AND EVALUATION**

Om Ankush Athare, Sachin Aglawe, Vijay Jadhav
Rashtrasant Janardhan Swami College of Pharmacy, Kokamthan, Kopargaon, Maharashtra, India. 423601.
Omathare2002@gmail.com

The present investigation aimed to design and evaluate mucoadhesive buccal tablets of Glipizide employing Carbopol 974P (CP) in combination with cashew nut tree gum and Aegle marmelos gum as bioadhesive polymers, along with ethyl cellulose (EC, 50 mg) as an impermeable backing layer. A total of nine formulations were developed using the direct compression method and systematically characterized for swelling behavior, surface pH, bioadhesive strength, in-vitro drug release, and diffusion profiles. All formulations complied with pharmacopoeial standards for hardness, friability, weight variation, and drug content. The swelling index was found to increase proportionally with polymer concentration, while surface pH values remained near neutrality, indicating compatibility with buccal tissues. The release and diffusion of Glipizide were strongly influenced by the ratio of natural polymers, where higher proportions of Aegle marmelos gum led to reduced drug release but enhanced mucoadhesive strength and swelling capacity. Drug–polymer interactions were further confirmed by FTIR and DSC analyses, ensuring formulation stability. The study demonstrates that combining synthetic and natural gums offers a promising approach to achieving controlled release and prolonged buccal residence time for Glipizide.

**Keywords:** Cashew nut tree gum, Swelling index, Aegle marmelos gum

**PC-542**

**DESIGN AND EVALUATION OF A DUAL-RELEASE CAPSULE SYSTEM FOR METOPROLOL: COMBINING IMMEDIATE AND FLOATING EXTENDED RELEASE TABLETS**

Saurabh Rajendra Kharat, Om Athare, Nitin Jain
Rashtrasant Janardhan Swami College of Pharmacy, Kokamthan, Kopargaon, Maharashtra, India. 423601.
saurabhkharat888@gmail.com

Metoprolol, a selective β-blocker, is widely prescribed for the management of hypertension, angina, and heart failure. Conventional single-unit, floating, and sustained-release formulations often fail to maintain optimum plasma concentrations, thereby limiting therapeutic efficacy and bioavailability. The present research focuses on the development of a single-dose capsule dosage form incorporating both an Immediate Release (IR) and a Floating Extended Release (ER) tablet of Metoprolol to achieve biphasic drug release. Three formulation batches were prepared using different combinations of IR and ER tablets and were evaluated through pre- and post-formulation parameters, all of which complied with pharmacopeial limits. In vitro release studies were performed to compare drug release profiles of individual tablets with the dual-tablet capsule system. The optimized capsule demonstrated an initial rapid release from the IR tablet, achieving therapeutic plasma concentration promptly, followed by sustained drug release from the floating ER tablet, maintaining prolonged plasma levels. This novel dual-tablet capsule system showed superior release characteristics compared to conventional approaches, offering a promising strategy for enhancing bioavailability, patient compliance, and therapeutic efficacy of Metoprolol in cardiovascular therapy.

**STABILITY ENHANCEMENT OF MOXIFLOXACIN ORAL SUSPENSION THROUGH NATURAL AND SEMI-SYNTHETIC POLYMER-BASED FORMULATION APPROACHES**

Aparna Peri, Srilakshmi Surampally
Department of pharmaceutics, R. b. v. r. r womens college of pharmacy, Hyderabadbad, Telangana, India-500027.
82mantha@gmail.com

Moxifloxacin is a potent fluoroquinolone antibiotic used in the treatment of a wide spectrum of bacterial infections. The present investigation was aimed at developing and evaluating stable moxifloxacin oral suspensions using natural (Karaya gum, Isabgol husk) and semi-synthetic (sodium carboxymethyl cellulose, Na-CMC) polymers as suspending agents. Each polymer was incorporated at concentrations of 0.5%, 1.0%, and 1.5% w/v, and the formulations were assessed for viscosity, flow behavior, sedimentation volume, particle size, redispersibility, and drug content uniformity. Batch optimization was carried out using design of experiment (DoE) software. The optimized formulation was subjected to stability studies as per ICH guidelines. Trial batches played a crucial role in formulating the suspension.The results revealed marked differences in performance among the polymers. Sodium cmc suspensions showed optimal rheological properties, Isabgol suspensions demonstrated excessive swelling, irregular particle sizes , and unstable flow, with viscosities of 200 cps, 310 cps, and 450 cps and high sedimentation volume ratios Comparative analysis indicated that Na-CMC at 1.5% provided the best balance of viscosity, flow, and stability, ensuring pourability and uniform dosing. The study concludes that while natural polymers contribute to suspension stability, Na-CMC offers superior performance for enhancing the physical stability of moxifloxacin oral suspension. Stability studies were conducted for up to 30 days under both room temperature and refrigerated conditions, following ICH guidelines. The optimized batch demonstrated stability and successfully passed the stability tests. A stable oral suspension dosage form of the moxifloxacin was successfully developed, meeting pharmacopoeial standards and offering a patient-friendly alternative for those with difficulty swallowing solid dosage forms.

**Keywords:** Moxifloxacin Hydrochloride, Oral suspension formulation, Sodium carboxy methyl cellulose, Karaya gum, Isabgol, Suspending agents, Viscosity, Stability studies, pH, Sedimentation volume, Flow rate, Redispersibility, Dissolution rate, Particle size

**FORMULATION AND EVALUATION OF ZALTOPROFEN LOADED NANODISPERSIONS AND FAST DISINTEGRATING ORODISPERSIBLE FILMS: AN APPROACH TO ENHANCE EFFICACY**

Selvakumar Muruganantham, Shanmugarathinam Alagarsamy
Department of Pharmaceutics, Vivekanandha Pharmacy College for Women, Sankari, Salem, Tamil Nadu, India – 637303.
murugaselva93@gmail.com

Drug delivery innovations are critical to overcoming challenges associated with poorly water-soluble drugs. Zaltoprofen (ZLT), a COX-2 selective inhibitor and BCS class II compound, has poor aqueous solubility and low oral bioavailability as a result of considerable first-pass hepatic metabolism. This study explored two delivery strategies, such as nanodispersions (NDs) for intravenous administration and fast disintegrating orodispersible film (FDOFs) for oral delivery, to enhance ZLT solubility, bioavailability, and therapeutic efficacy. In our previous work, Zaltoprofen loaded nanodispersions (ZLTNDs) were formulated, characterized, and evaluated in vitro (published). Based on the above findings, this study was carried out to investigate their hemocompatibility, cellular uptake, and in vivo anti-arthritic properties. Optimized ZLTNDs exhibited excellent hemocompatibility with negligible haemolysis, efficient macrophage internalization, and significant anti-arthritic effects, achieving a 22.64% reduction in paw swelling and restoration of hematological parameters in CFA-induced rheumatoid arthritis rats. In parallel, Zaltoprofen loaded FDOFs (ZFDOFs) were prepared by the solvent casting method by using pullulan, sodium starch glycolate, and PEG-400. Our optimized films exhibited fast disintegration (14-22 s), high percentage drug release (65-92% in 2 min), and were stable up to 90 days. FTIR, DSC, and XRD confirmed the absence of drug–excipient interactions. Pharmacokinetics evaluation also showed an increase in absorption and an optimization of bioavailability over unmodified ZLT. The solubility, efficacy of the therapy, and patient compliance were significantly enhanced in both delivery systems. The results make nanodispersions and FDOFs a promising and complementary platform to deliver ZLT with potential clinical benefits over conventional formulations.

**Keywords:** Zaltoprofen, nanodispersion, fast disintegrating orodispersible film, bioavailability, rheumatoid arthritis.

**ENHANCEMENT OF BIOAVAILABILITY OF PITAVASTATIN LOADED SOLID LIPID NANOPARTICLES**

Zareena Begum Shaik, Amzadkhan Pathan, Harikiran Lingabathula

ISBN: 978-81-980623-8-3

Department of Pharmaceutics, Shri Jagdishprasad Jhabarmal Tibrewala University, Jhunjhunu, Rajasthan, India-333010.
shaikzareena61@gmail.com

Pitavastatin (PS) is a lipid-lowering drug widely used to treat hypercholesterolemia. Its clinical effectiveness is hindered by poor aqueous solubility and extensive hepatic first-pass metabolism, resulting in low oral bioavailability. To address this limitation, solid lipid nanoparticles (SLNs) and coated SLNs were developed and evaluated as potential drug delivery systems to enhance PS bioavailability. Seven SLN formulations were prepared using three different lipids, either alone or in combination, along with two stabilizers. To further improve drug release and stability, two polymers; chitosan (CS) and alginate (AL) were used as coating materials at two different concentrations. The formulations were assessed for particle size, zeta potential, in vitro drug release, rheological behavior, and in vivo bioavailability. The results showed that both uncoated and coated SLNs displayed shear-thinning behavior. Specifically, the viscosity of F5-CS (1% chitosan-coated) decreased from 432 to 173 cp as the shear rate increased from 20 to 40 rpm, indicating favorable flow characteristics. The F5 formulation (uncoated) exhibited a particle size of 262.4 ± 2.98 nm and demonstrated a higher drug release compared to other formulations. Coating F5 with 1% chitosan enhanced its particle size to 513.8 ± 69.72 nm. In vivo pharmacokinetic studies revealed a significant increase in PS plasma concentration and overall bioavailability for SLNs. The area under the curve ($AUC_{0\rightarrow24}$) for the PS, F5, and F5-CS (1%) was 298, 1794.61, and 3518.26 ng·h/mL, respectively. These findings confirm that SLNs, particularly chitosan-coated ones, are promising systems for enhancing the oral delivery of poorly soluble drugs like pitavastatin.

## OPTIMIZATION OF SELF-EMULSIFIED NANOEMULSION (SNEDDS) OF AZELNIDIPINE BY D-OPTIMAL DESIGN APPROACH TO ENHANCE THE SOLUBILITY

Sarika Jadhav, Shashikant Dhole, Nilesh Kulkarni
Department of Pharmaceutics, PES Modern College of Pharmacy, For Ladies, Moshi, Savitribai Phule Pune University, Pune, India – 412105.
jadhavsarikapharma@gmail.com

The objective of the study was to enhance the solubility of poorly soluble BCS class II drug azelnidipine (AZE) by formulating self-emulsified nanoemulsion (SNEDDS) using D-optimal design approach. The components oleic acid (oil), S mix (tween 20 (surfactant), transcutol P (cosurfactant) 3:1) and their concentration range were finalised by saturation solubility study and pseudo-ternary phase diagram. The D optimal design approach was employed to optimized formulation variables. In evaluation it was found that SNEDDS (15 % oleic acid, 70% Smix and 15 % water), formulated by low-energy method exhibited maximum entrapment efficiency (99.12 % ± 0.5 %), drug content (99.35 ± 0.10 %), percentage transmittance (98.85 ± 0.25), minimum self-emulsification time (22.00 ± 1 s), droplet size (350.8 ± 5 nm) and polydispersity index (0.30 ± 0.05) and acceptable zeta potential -26.5 mv. Solid SNEDDS was characterised by FTIR analysis showed significant interactions with the emulsifying agents and the solvent matrix, confirming effective incorporation into the nanoemulsion formulation. Broad and significant shift in the endothermic peak in DSC thermogram, different and diffused diffractogram of XRD compared to pure drug indicates the amorphization. In FE-SEM characterization exhibits the nanosized particles in between 200-300 nm which proves successful nanonization, absence of crystalline edges confirms the amorphization. The four times improvement in dissolution potential in pH 6.8 buffer solution at 60 minutes was confirmed by an in vitro dissolution study. Thus, it can be concluded that this study successfully formulates self-emulsified nanoemulsion (SNEDDS) of azelnidipine by D-optimal design approach to enhance the solubility.

**Keywords:** Azelnidipine, SNEDDS, D-optimal design approach.

## PANCHAGAVYA MEDIATED CHITOSAN CONJUGATED NANOCOMPOSITES: ECO-SYNTHESIS, CHARACTERIZATION AND ITS THERAPEUTIC ASSESSMENT FOR AGRICULTURAL SUSTAINABILITY

Manali A. Vaidya, Shailendra S. Gurav
Goa College Of Pharmacy, Panjim – Goa
Manali26@Gmail.Com

The current study employs Panchagavya (PG) conjuncted ZnO and chitosan (CS) nanocomposites to create a sustainable and biodegradable plant growth enhancer. The crop-improvement qualities of PG and the nanoscale features of ZnO encourage plant growth while using less chemicals. Unique particle architectures were revealed through the synthesis and characterization of PG-ZnONP nanoparticles (NPs) and CS/PG-ZnONC nanocomposites (NCs) using UV-Vis, XRD, SEM, and HRTEM. SEM results revealed hexagonal wurtzite structure for PG-ZnONPs, while CS/PG-ZnONCs exhibited oval rod-like structures. TEM confirmed nanosized particles for PG-ZnONPs and CS/PG-ZnONCs. Dynamic light scattering (DLS) analysis demonstrated that PG-ZnONPs had an average size of 234.4 nm, with a zeta potential of -22.4 mV, whereas CS/PG-ZnONCs had an average size of 496.5 nm with a zeta potential of 1.11 mV. Seed germination and pot studies on mung bean plants determined that 125 mg/L for PG-ZnONPs and 62 mg/L of CS/PG-ZnONCs were the best doses, exhibiting enhanced growth metrics and hence suited for foliar spraying. Mung seedlings treated with PG-ZnONPs at this concentration had an average root and shoot length of 2.42 cm and 5.20 cm, respectively. In comparison, seedlings treated with CS/PG-ZnONCs had root and shoot lengths of 2.48 cm and 10.17 cm, indicating that the concentration is suitable for foliar treatment. In the pot studies, many growth characteristics were examined across seven treatments, with the findings revealing that CS/PG-ZnONCs performed better in growth than the other treatments. Research therefore highlights sustainable agriculture.

## NANOCARRIER-BASED ENHANCEMENT OF SILYBIN'S ORAL ABSORPTION AND HEPATOPROTECTIVE EFFICACY USING DEOXYCHOLIC ACID FUNCTIONALIZED CHITOSAN

Srinivas Mutalik
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal 576104, Karnataka, India
ss.mutalik@manipal.edu

Silybin is a potent liver-protective agent, but its clinical use is limited by very low oral bioavailability (~0.95%) due to poor solubility. We developed deoxycholic acid-grafted chitosan–lecithin nanoparticles (DCS-LC NPs) to enhance intestinal absorption and hepatoprotection. The amphiphilic polymer was designed to exploit bile acid transport pathways, improving oral uptake. Nanoparticles were prepared via ionic gelation and optimized using Box–Behnken design, yielding favourable particle size, drug loading, sustained release, and excellent biocompatibility. Ex vivo and in vivo studies confirmed enhanced intestinal permeation and a 2.9-fold increase in oral bioavailability compared to free Silybin. Caco-2 cell assays verified the safety of the formulation. In a $CCl_4$-induced hepatotoxicity model, DCS-LC NPs demonstrated superior liver protection, supported by improved biochemical and histological markers. These findings highlight DCS-LC nanoparticles as an effective oral delivery system for poorly soluble hepatoprotective compounds, offering a promising strategy for liver-targeted nanomedicine and improved therapeutic outcomes.

## IN-SILICO DRUG REPOSITIONING OF DICLOFENAC SODIUM AS A PPAR-Γ MODULATOR FOR OBESITY

Sanjeevini M Hukkeri, Bharath Srinivasan
Department of Pharmaceutics, Faculty of Pharmacy,
M.S. Ramaiah University of Applied Sciences Bangalore, Karnataka, India – 560 054.
sanjeevinimh@gmail.com

In the current research, in-silico and bioinformatics tools were employed to explore the repurposing of Diclofenac sodium as a therapeutic candidate for obesity by targeting Peroxisome Proliferator-Activated Receptor Gamma (PPAR-γ). The objective was to identify obesity-

ISBN: 978-81-980623-8-3

associated molecular targets and evaluate the binding potential of Diclofenac through computational modeling. Target prioritization was performed using the Open Targets platform which identified PPAR-γ with a disease association score of 0.6993. Protein–protein interaction analysis using the STRING database revealed a network of 6 nodes and 11 edges with an average node degree of 3.67, clustering coefficient of 0.822 and enrichment p-value of $3.77 \times 10^{-15}$, confirming strong biological relevance. Molecular docking studies using AutoDock Vina demonstrated that Diclofenac exhibited a binding energy of –7.91 kcal/mol comparable to the co-crystal ligand (–10.3 kcal/mol). Stable interactions were observed with residues GLU343, ILE341 and SER342 which played key roles in ligand stabilization within the receptor pocket. Molecular dynamics simulations performed with Desmond for 100 ns further validated the complex stability with RMSD stabilizing at 2.5–3.0 Å for the protein and 2.0–2.5 Å for the ligand after 20 ns. RMSF plots confirmed minimal fluctuations at binding site residues and interaction timeline analysis showed persistent contacts with GLU343 (74%), ILE341 (62%) and SER342 (49%) maintaining stable interactions. Further, Diclofenac sodium demonstrated strong and stable binding comparable to the native ligand supporting its potential for therapeutic application in obesity management.

## CO-ADMINISTRATION OF GLIBENCLAMIDE WITH QUERCETIN FOR BIOAVAILABILITY ENHANCEMENT

Shraddha S. Joshi and Pratima A. Tatke
C. U. Shah College of Pharmacy, SNDT Women's University Mumbai, Maharashtra, India- 400049.
shraddha25.sj@gmail.com

In the present study, the enhancement of bioavailability of poorly soluble drugs was explored using natural phytoconstituents. The objective was to investigate the potential of quercetin, a flavonoid found in vegetables and citrus fruits, as a bioenhancer to improve the therapeutic performance of glibenclamide (GBC), a BCS Class II drug used in diabetes management, which exhibits poor solubility and inconsistent bioavailability. Quercetin has shown potential to inhibit key metabolic enzymes such as cytochrome P450 3A4 (CYP3A4) and P-glycoprotein (P-gp), which may enhance drug absorption and reduce first-pass metabolism. Analytical and bioanalytical methods were developed and validated for the simultaneous estimation of glibenclamide and quercetin using HPLC. A pharmacokinetic study was conducted to assess the impact of quercetin co-administration on the oral bioavailability of glibenclamide in rats. The findings showed a moderate increase in Cmax, rising from 0.4052 µg/ml in Group I (glibenclamide alone) to 0.6329 µg/ml in Group II (glibenclamide with quercetin). Additionally, a significant enhancement in AUC was observed in Group II, which received glibenclamide along with quercetin, achieving an AUC of 5.089 µg·h/mL, compared to 2.574 µg·h/mL in Group I. This improvement suggests that quercetin effectively enhances bioavailability of glibenclamide by inhibiting its metabolic degradation and extending its duration of action. These findings underscore the potential of natural phytoconstituents, such as quercetin, to act as bioenhancers in enhancing the therapeutic efficacy of poorly soluble drugs like glibenclamide.

**Keywords:** Glibenclamide, Bioavailability, Quercetin, Phytoconstituents.

**PC-551**

## TO STUDY THE RELEASE KINETICS OF ANTI-COAGULANT DRUG IN PREVENTION OF THROMBOEMBOLISM

Bhargavi Joshi, Swati M.Keny and Sachi S Sinai Kolwalkar
Department of Pharmaceutics, PESs Rajaram and Tarabai Bandekar College of Pharmacy, Farmagudi-Ponda, Goa, India-403401.
swatimayur33@gmail.com

The COVID-19 pandemic has significantly increased the prevalence of thromboembolic complications, prompting widespread use of anticoagulants such as Rivaroxaban in post-COVID-19 management. The present study focuses on the formulation and evaluation of mouth dissolving films (MDFs) of Rivaroxaban complexed with β-cyclodextrin to enhance solubility and ensure rapid onset of action through oral transmucosal delivery. MDFs were prepared by the solvent casting method using various combinations of film-forming polymers—HPMC E15, PVP K30, and PVA—along with plasticizers (PEG 400 and glycerine), a disintegrant (sodium starch glycolate), and a sweetener (aspartame). Six formulations (F1–F6) were developed and evaluated for physicochemical properties including surface pH, thickness, folding endurance, tensile strength, weight uniformity, and drug content. Among them, F-2 (HPMC E15 + PVP K30) and F-5 (HPMC E15 + PVA) showed superior performance in in-vitro drug release studies, with cumulative drug release of 98.70% and 94.56% respectively within 60 minutes. Drug release kinetics followed the Korsmeyer–Peppas model with $r^2$ values of 0.9961 (F-2) and 0.9933 (F-5), indicating Fickian diffusion as the dominant mechanism. F-2 demonstrated a faster onset, ideal for immediate therapeutic action, whereas F-5 showed sustained release suitable for prolonged effect and enhanced mucosal adhesion. These results suggest that the developed MDFs, particularly F-2 and F-5, hold promise as effective, patient-friendly delivery systems for Rivaroxaban, particularly suited for rapid therapeutic intervention due to their efficient drug release profiles.

**Keywords:** Rivaroxaban, β-cyclodextrin, HPMC E15, PVP K30, and PVA.

**PC-552**

## OPTIMISATION OF LOW DENSITYVINDOLINE FLOATING PULSATILE SYSTEMS FOR THE THERAPY OF CANCER EMPLOYING HIBISCUS ESCULENTUS GUM AS A BIODEGRADABLE AND BIOCOMPATIBLE NOVEL NATURAL TIMED RELEASE POLYMER

A. Bharathi
KVSR Sidhhartha College of Pharmaceutical Sciences, Siddhartha Nagar, Vijayawada, A.P, India
bharathi.arigela004@gmail.com

The present research focuses on the design and optimization of a low-density floating pulsatile system of vindoline for the therapy of cancer, employing Hibiscus esculentus gum, a biodegradable and biocompatible novel natural timed-release polymer. The therapeutic rationale was to achieve a defined lag phase, allowing a drug-free interval, followed by a rapid burst release of vindoline to coincide with tumor cell cycle sensitivity, while ensuring gastric retention by maintaining system buoyancy. A $2^3$ full factorial design was employed to evaluate the effect of three critical formulation factors—polymer concentration, effervescent agent level, and coating thickness—on dependent variables such as lag time, percentage drug release, and floating duration. The formulations were systematically characterized for floating lag time, total floating duration, in-vitro drug release kinetics, surface morphology, and drug–polymer compatibility using FTIR and DSC techniques. Statistical analysis revealed that polymer concentration and coating thickness significantly modulated the lag period, whereas the effervescent agent level had a dominant influence on buoyancy parameters. The optimized formulation demonstrated a lag time of 2.1 ± 0.2 h, a burst release of 86.5 ± 1.3% within 90 min, and a floating duration exceeding 10 h, aligning well with the predefined Quality Target Product Profile. The outcomes of this investigation highlight the potential of Hibiscus esculentus gum as a novel natural timed-release polymer in formulating gastro-retentive pulsatile delivery systems. Such systems can provide site-specific, time-programmed drug delivery, offering improved therapeutic outcomes and reduced toxicity in cancer management.

**Keywords:** Vindoline, Hibiscus esculentus gum, floating pulsatile system, factorial design, cancer therapy.

**PC-553**

## FORMULATION AND CHARACTERIZATION OF POLYHERBAL LOZENGES FOR THE TREATMENT OF MOUTH ULCER

Mr. Sarthak Pohokar, Ms. Shubhangi Pillewan And R.B.V. Nagarjuna Yadav
G.H. Raisoni University, School of Pharmacy, Amravati, Maharashtra

Mouth ulcers, often called oral ulcers, often affect the mucosal lining of the oral cavity. The pain and suffering they inflict may make it difficult to do everyday tasks like eating and speaking. Numerous conditions, including autoimmune illnesses, trauma, infections, malnourishment, and systemic problems, can result in these ulcers, among all the types, recurrent aphthous stomatitis (RAS) is the most prevalent. Synthetic medications like corticosteroids, analgesics, and antiseptics have long been used to treat mouth ulcers. Nevertheless, these therapies

ISBN: 978-81-980623-8-3

frequently have unfavourable side effects and are not very good at accelerating healing. Because of its medicinal potential, safety, and biocompatibility, herbal medicine has drawn interest as a possible substitute. Lozenges' sedative properties, targeted drug release, and extended contact duration have made them a preferred medication administration method for treating oral ulcers. Unlike traditional treatments like mouthwashes and gels, lozenges dissolve gradually in the oral cavity, ensuring a continuous release of active components for improved therapeutic efficacy. Formulation and evaluation of polyherbal lozenges to treat oral ulcers is the main objective of this research. The herbal ingredients utilized in the composition were chosen because of their anti-inflammatory, antibacterial, and wound-healing qualities. In order to promote greater healing and longer-lasting therapeutic effects, the lozenges were created to increase medication retention in the oral cavity. The prepared lozenges were evaluated using a number of physicochemical tests, such as hardness and disintegration time. Their effectiveness in lowering inflammation and accelerating ulcer healing was also evaluated in vitro.

**Keywords:** Mouth ulcer, lozenges, drug delivery, anti-inflammatory, wound healing and polyherbal therapy.

## FORMULATION AND EVALUATION OF POLYHERBAL LOZENGES

Ms. Bhumika Mahajan And Dr.B.V. Nagarjuna Yadav
G.H. Raisoni University, School of Pharmacy, Amravati, Maharashtra

Bacteria or viruses are typically the cause of throat infections. Since their invention in 1900 BC, lozenges have remained a market favorite. Using a tasty solid dose form, lozenges are taken orally. In order to lubricate and soothe irritated throat tissues, lozenges are solid preparations that typically comprise one or more substances in a sweetened, flavored base. The creation and assessment of polyherbal lozenges to reduce throat infection symptoms were done in this research work. Liquorice [glycerrhiza glabra], Quercitin, Vasaka [Adhatoda vasica], Mint [Mentha spicata], Tulsi [Ocimum Tenuiflorum], and Ginger [Zingiber officinale] are traditionally used as cough suppressants and for colds and flu. The other ingredients in the polyherbal extract-based lozenge include honey [Apis mellifera] and jaggery [Saccharum officinarum L.], which have a nourishing and calming effect on the respiratory tract's mucous membrane. Before creating the polyherbal through macroscopic evaluation, each individual herbal medication is put through a number of tests. Their solubility, melting and boiling points, FTIR, DSC, and preliminary test were all performed. The physicochemical properties of the polyherbal lozenges, including their thickness, diameter, disintegration, hardness, weight change, and macroscopic features, were assessed. The goal of the current study is to create and assess a herbal remedy that is safe, effective, and has very few adverse effects or symptoms of a throat infection. The prepared lozenges have the greatest advantages over the other dosage forms: they are easy to deliver to both children and elderly people, they taste delicious, they prolong the duration of the drug in the oral cavity to release a specific effect, they are simple to create, and they don't require water intake to be administered.

**Keywords:** Lozenges, Polyherbal Extract, Side effects and Throat Infection.

## "PHARMACOKINETIC PROFILING OF ATENOLOL AND TULSI EXTRACT: IMPLICATIONS FOR CARDIOPROTECTIVE THERAPY"

Chetan Savant, V. H. Kulkarni and Prasanna Habbu
Post Graduate Department of Pharmacology, SET's College of Pharmacy, S.R.Nagar, Dharwad, Karnataka, India – 580002
chetan.savant@yahoo.com

This study explores the pharmacokinetic interaction between Atenolol (AT), a cardioselective β-blocker, and Ursolic acid, a key bioactive compound in Standardized Extract of Ocimum sanctum (SEOS), following oral administration in rats. The objective was to evaluate changes in plasma concentration and pharmacokinetic parameters when both agents are co-administered. Standard solutions of AT and Ursolic acid were prepared in methanol at 1000 µg/ml and serially diluted to obtain calibration ranges of 20–120 µg/ml and 100–600 µg/ml, respectively. Mixed standards were spiked into rat plasma and processed using protein precipitation with acetonitrile, followed by centrifugation and filtration. Plasma samples were analyzed using HPLC to determine drug concentrations over time. Results indicated a significant reduction in Cmax and $AUC_{0-10}$ for both compounds when administered in combination. Atenolol's Cmax decreased from 118.99 µg/ml to 95.86 µg/ml, and AUC from 694.3 to 433.9. Ursolic acid showed a similar decline in Cmax (10.91 µg/ml to 8.38 µg/ml) and AUC (15.49 to 11.33). Additionally, elimination rate constants (Ke) increased, while half-life ($t_1/_2$), volume of distribution (Vd), and clearance (Cl) values were reduced in the combination group. In conclusion, co-administration of SEOS and Atenolol alters the pharmacokinetic profile of both agents, suggesting potential herb-drug interactions that may impact therapeutic efficacy. These findings warrant further investigation to guide safe clinical use of herbal supplements alongside conventional cardiovascular medications.

**Keywords:** Atenolol, Ursolic acid, Pharmacokinetics, Herb-drug interaction

## FORMULATION, EVALUATION AND MOLECULAR DOCKING STUDY OF GHEE-BASED ANTI- EPILEPTIC NANOPARTICLES FROM BAUHINIA PURPUREA

Ms. Dhanashree Pimpalkar And Mr. Yaswanth Nakathe
School Of Pharmacy, G.H. Raisoni University Amravati, Maharashtra.

A chronic neurological disorder that has an immense effect on a patient's quality of life is epilepsy. Current therapeutic options often have severe side effects, highlighting the need for novel, effective, and safer treatments Bauhinia Purpurea a plant widely used in traditional medicine, has shown promising anticonvulsant activity, which has been traditionally attributed to its rich phytochemical profile, including flavonoids, triterpenoids, and saponins. Its inadequate water solubility and low absorption, however, may restrict its therapeutic effectiveness. By designing an extract delivery formulation using ghee-based nanoparticles, this work seeks to get beyond such limitations. The solubility, bioavailability, and targeted administration of the active phytochemicals are anticipated to be enhanced by the use of ghee, a conventional lipid that is a great carrier for lipophilic substances, in a nanostructured lipid carrier (NLC) system. The creation of ghee-based nanoparticles loaded with a hydroalcoholic extract utilizing a high-energy approach will be the primary focus of the study. Zeta potential, size, shape, and drug entrapment efficiency will all be evaluated for the nanoparticles To ensure the nanoparticles anti-epileptic potential, the study will carry out a through in vitro assessment after formulation. Using well-established cellular or in vitro models relevant to epilepsy will be part of this. A molecular docking study to clarify the mechanism of action of the important phytochemicals will be a crucial component of this investigation. The study will use computational techniques to forecast the binding affinities and interactions of Bauhinia Purpurea main constituents (such as certain flavonoids and triterpenoids) with important molecular targets linked to epilepsy, including voltage-gated ion channels and GABA receptors. The docking study's findings will serve as a solid justification for the reported in vitro effects and direct further formulation enhancement. In summary, this research presents a novel approach to enhance the therapeutic efficacy of Bauhinia Purpurea in the management of epilepsy disease. This research work opens the possibility to a safer and more effective anti-epileptic drug by combining traditional knowledge (using Ghee) with modern nanomedicine and computational biology (molecular docking) to provide a comprehensive analysis from formulation to a mechanistic understanding.

**Keywords:** Molecular Docking, Anti-Epileptic, Nanoparticles, and Bauhinia Purpurea.

## INNOVATIONS IN ADVANCED DRUG DELIVERY SYSTEMS: A NEW ERA OF TARGETED THERAPY

Avantika Pofare , Mr. Sumit Kolte, Dr.Vinod Thakre
Nagpur College of Pharmacy, Hingna Rd, Wanadongri ct, Nagpur, Maharashtra 441110
Avantikapofare@gmail.com

Innovations in advanced drug delivery systems have revolutionized the field of medicine, ushering in a new era of targeted therapy. These systems enhance therapeutic efficacy by delivering drugs precisely to the site of action, minimizing systemic side effects and improving patient outcomes. This paper explores recent advancements in drug delivery

ISBN: 978-81-980623-8-3

technologies, including nanocarriers, liposomes, dendrimers, and microneedles, which are designed to overcome limitations of traditional methods. Emphasis is placed on the role of stimuli-responsive systems, such as pH- or temperature-sensitive carriers, that release drugs in response to specific physiological conditions. Additionally, the integration of biotechnology and nanotechnology has enabled the development of personalized delivery platforms, such as CRISPR-based systems and RNA therapeutics, offering solutions for complex diseases like cancer, neurodegenerative disorders, and autoimmune conditions. Advances in biomaterials and smart polymers have further improved drug stability and bioavailability. Challenges, including scalability, regulatory hurdles, and biocompatibility, are discussed alongside promising strategies for addressing these barriers. By focusing on precision, sustainability, and patient-centric approaches, advanced drug delivery systems represent a paradigm shift in therapeutic modalities. This review underscores their potential to transform modern medicine and pave the way for more effective, safe, and accessible treatments across diverse clinical applications.

## FORMULATION AND EVALUATION OF POLYMERIC NANOFORMULATIONS LOADED WITH AMANTADINE HYDROCHLORIDE FOR THE TREATMENT OF PARKINSON'S DISEASE

Ms. Saloni Korde And Dr.B.V. Nagarjuna Yadav
G.H. Raisoni University, School Of Pharmacy, Amravati, Maharashtra

Parkinson's disease represents the second most prevalent neurodegenerative disorder subsequent to Alzheimer's disease. Nanoparticles comprising Amantadine hydrochloride were synthesized utilizing PLGA polymers. Prior to the formulation of Amantadine hydrochloride polymeric nanoparticles, preformulation investigations were conducted to assess the physical and chemical compatibility between the drug and the polymer through FTIR and DSC. Subsequently, the formulated nanoparticles were characterized concerning particle size, polydispersity index, zeta potential, drug content, entrapment efficiency, and morphology via scanning electron microscopy, in addition to evaluating drug-excipient compatibility. The FTIR analysis inferred that no significant interactions transpired between the drug and the polymers utilized in the current investigation. The FTIR analysis inferred that no significant interactions transpired between the drug and the polymers utilized in the current investigation. The nanoformulations of Amantadine hydrochloride were synthesized utilizing varying concentrations of polymeric materials. The nanoparticulate formulation prepared with a PLGA 1:4 ratio demonstrated commendable outcomes, specifically an average particle size of 178.5 nm, a polydispersity index of 0.185, a zeta potential of -25.9 mV, a drug content of 80.44%, and an entrapment efficiency of 84.67%. Furthermore, the particle morphology as assessed by SEM revealed a mean particle diameter in the vicinity of 120 nm, with the nanoparticles exhibiting a spherical shape and a smooth surface texture. In vitro drug release investigations suggested a controlled and sustained release of the drug over a duration of 24 hours. Based on these characteristics, it was determined that the nanoprecipitation technique was a practical way to successfully include amantadine Hcl with a high entrapment efficiency. Thus, as a drug delivery vehicle, polymeric nanoparticles improve the bioavailability of drugs that are low lipophilicity and poorly soluble in water, such as amantadine HCl.

## OPTIMIZATION AND CHARACTERIZATION STUDY OF VINORELBINE TARTRATE-CONTROLLED RELEASE TABLETS WITH SBA-15 NANOMATERIAL

Sushma Desai, Chandrasekhara Rao Baru and Mohan Varkolu
Department of Pharmaceutics, GITAM School of Pharmacy, GITAM (Deemed to be) University, Rudraram, Patancheru, Hyderabad, Telangana, INDIA.
sdesai@gitam.in

For the current study, Nanomaterial Santabarbara amorphous -15 (SBA-15) a versatile carrier has been selected to prepare controlled release tablets of vinorelbine tartrate. The objective of this project is to study the effect of nanomaterial on drug release by formulation of oral solid dosage forms with the highly porous SBA-15 nanomaterial. Pre-formulation studies for compatibility conducted by FTIR study and morphology study by XRD. Trials conducted in optimizing the formulation into a oral solid dosage forms by direct compression method and further assessed for drug release by spectrophotometric method and thermodynamic studies. The observed results in pre-formulation by spectroscopic method FTIR revealed good compatibility with SBA-15 showing no change in characteristic peak of pure drug. morphology study by XRD revealed amorphous nature of the nanomaterial and compatibility with the drug. The TGA studies under air conditions at temperature range 30-5000 C revealed complete mass degradation to less than 0.5% at 5000 C. The drug release by dissolution study revealed that SBA-15 shows good controlled release effect on vinorelbine tartrate by 18 % at 60 min compared with pure drug 40% release in 6.8 pH phosphate buffer. With the results it can be concluded that SBA-15 nanomaterial can be effectively used as a carrier to control the vinorelbine tartrate release by oral dosage forms.

**Keywords:** vinorelbine tartrate, SBA-15, controlled release, nanomaterials.

## DEVELOPMENT OF POSACONAZOLE LOADED NANOSTRUCTURED LIPID CARRIERS FOR IMPROVED ANTIFUNGAL EFFICACY IN MUCORMYCOSIS

Mr.Shubham Vijay Chavan, Dr. Mohamed Zerein Fathima
Department of Pharmaceutical Chemistry and Analysis.
Vels Institute of Science Technology and Advanced Studies Pallavaram, Chennai, Tamilnadu, India.
shubchavan808@gmail.com

Lipid-based drug delivery systems have the potential capacity to entrap both hydrophobic and hydrophilic molecules, enhance the bioavailability of poorly aqueous soluble drugs, and protect them from untimely degradation. Nanostructured lipid carriers (NLCs), the second generation innovative lipid nanoparticle that act as a bioactive carrier system. Nanostructured lipid carriers are biocompatible drug carriers used for hydrophilic as well as hydrophobic drugs. NLCs are high permeability, better physical stability, huge loading capacity and most affordable (less expensive than polymeric/surfactant based carriers). Many antifungal drugs currently available in market exhibit solubility and permeability problems and mostly belongs to BCS class-II and IV drugs so bioavailability is the major cause and could be resolved by formulating Posaconazole-loaded NLCs. NLCs have the usual particle diameter ranging 10-1000 nm. Posaconazole loaded NLCs were successfully formulated using the melt homogenization technique combined with ultrasonication. The rapid emergence and spread of the Covid-19 pandemic in India has highlighted the country's health-care system's failure to cope with the increasing number of cases. At its peak, over 400,000 cases were reported each day, and the country was not able to provide adequate resources to address the needs of its patients. Mucormycosis is caused by a group of molds known as mucormycetes. The most common species of these organisms is the Mucor and the Rhizopus. As of June 2021, there were over 40,000 cases of this disease in India. The NLCs were formulated using melt homogenization followed by ultrasonication, resulting in nanoparticles with a mean particle size of 300 to 400 nm and a positive zeta potential of 28 mV to 34 mV, confirming nanoscale dimensions suitable for ocular delivery with good stability against aggregation. The formulation exhibited the entrapment efficiency 74.23 % to 95.99%, indicating excellent drug incorporation, which is critical for ensuring sustained drug release and therapeutic efficacy. The formulation of Posaconazole NLCs was optimized using Box-Behnken design by considering surfactant concentration and lipid concentration as independent variables and particle size, entrapment efficiency and drug loading as dependent variables. Significance of the study to increase permeability, bioavailability, to provide sustained.

**Keywords:** Nanostructured Lipid Carriers, Posaconazole, Melt Emulsification, and Mucormycosis.

## REVOLUTIONIZING CANCER THERAPY: ADVANCING DRUG DELIVERY SYSTEMS WITH NANOPARTICLES FOR TARGETED AND EFFECTIVE TREATMENT

Riya A. Lanjewar , Mr. Sumit S. Kolte , Dr. Vinod Thakare

ISBN: 978-81-980623-8-3

Nagpur College of Pharmacy, Nagpur, Maharashtra.
lanjewarriya19@gmail.com

The advent of nanoparticles in cancer therapy has revolutionized drug delivery systems, enabling more precise and effective treatments. Traditional cancer therapies, such as chemotherapy and radiation, often result in significant off-target effects, leading to systemic toxicity and diminished patient quality of life. Nanoparticles, with their unique physicochemical properties, offer an innovative platform for targeted drug delivery, enhancing therapeutic efficacy while minimizing adverse effects. This review highlights recent advancements in nanoparticle-based delivery systems, including liposomes, polymeric nanoparticles, and dendrimers, designed to achieve controlled drug release, improved bioavailability, and enhanced tumor selectivity. Special emphasis is placed on the role of surface functionalization, such as ligand targeting and pH-responsive mechanisms, which enable nanoparticles to navigate biological barriers and achieve site-specific drug accumulation. Additionally, the integration of imaging agents into nanoparticles facilitates real-time monitoring of therapeutic outcomes. Despite promising preclinical results, challenges remain, including scalability, immunogenicity, and regulatory approval for clinical applications. Addressing these issues through interdisciplinary research is critical to translating nanoparticle-based systems from bench to bedside. By leveraging their potential for precision medicine, nanoparticles are poised to transform the landscape of cancer therapy, offering hope for improved outcomes and reduced burden on patients.

## INNOVATIVE BIOACTIVE STRIPS FOR PAIN RELIEF, INFECTION CONTROL, AND HEALING OF POSTPARTUM PERINEAL WOUNDS

Suraj Daulatrao Bendre, Sachin Bhagwat Aglawe & Vijay Bhausaheb Jadhav
Rashtrasant Janardhan Swami College of Pharmacy, Kokamthan, Kopargaon, Maharashtra, India, 423601.
surajbendre6374@gmail.com

Postpartum perineal trauma, often caused by episiotomy or spontaneous lacerations, is a major maternal health issue that results in pain, infection risk, and delayed healing, thereby impairing physical comfort and emotional well-being. Conventional treatments such as analgesics, antiseptic applications, and sitz baths offer only limited relief and are often inconvenient for regular use. To address these challenges, this work focuses on developing novel bioactive polymeric strips for direct application on perineal wounds. The strips are formulated using a biocompatible polymeric base integrated with natural bioactive agents and therapeutic additives known for their analgesic, antimicrobial, and wound-healing activities. The design aims to provide sustained release of actives, maintain a moist healing environment, and reduce microbial colonization while ensuring patient comfort and ease of application. Preformulation studies will examine compatibility between selected bio actives and the polymer matrix. The prepared strips will be characterized for thickness, tensile strength, folding endurance, surface pH, swelling index, content uniformity, and in vitro release profile. Antimicrobial potential will be evaluated against common postpartum pathogens, and wound-healing activity will be assessed using in vitro and ex vivo models. Irritation studies will confirm safety for sensitive perineal tissues. The project is expected to yield a novel, non-invasive, and patient-friendly therapeutic system that relieves pain, prevents infection, and promotes faster wound healing. If successful, these bioactive strips may serve as an effective alternative to conventional methods, offering a significant advancement in postpartum wound management and improving maternal health outcomes.

**Keywords:** Postpartum perineal trauma, Bioactive polymeric strips, Wound healing, Antimicrobial activity

## FORMULATION AND OPTIMIZATION OF ORODISPERSIBLE HERBAL TABLETS: A DOE-BASED APPROACH TO STANDARDIZATION

Sachin Bhagwat Aglawe, Vijay Bhausaheb Jadhav & Suraj Daulatrao Bendre
Rashtrasant Janardhan Swami College of Pharmacy, Kokamthan, Kopargaon, Maharashtra, India, 423601.
Sachinglw8@gmail.com

This study aimed to develop and optimize orodispersible herbal tablets incorporating Achyranthes aspera Linn. extract. To achieve rapid disintegration, Crospovidone and Sodium Starch Glycolate were used as superdisintegrants, while β-cyclodextrin was added to enhance the solubility of bioactive constituents. Formulations were designed using a Design of Experiments (DOE) approach, considering Crospovidone and Sodium Starch Glycolate as independent variables and disintegration time along with cumulative drug release as dependent responses. The prepared tablets were evaluated for critical quality parameters, including hardness, friability, weight variation, wetting time, in vitro dispersion time, water absorption, and content uniformity. The optimized formulation (F6) demonstrated excellent performance, with a disintegration time of 1.805 seconds, cumulative drug release of 98.04%, hardness of 2.98 kg/cm², friability of 1.58%, weight variation of 3.319%, wetting time of 34.4 seconds, water absorption capacity of 36%, and content uniformity of 99.5%. All values were within pharmacopeial limits, validating the reliability of the optimization model. The findings confirm that the synergistic action of Crospovidone and Sodium Starch Glycolate effectively enhanced tablet disintegration and dissolution, thereby improving the potential oral bioavailability of Achyranthes aspera Linn. extract. The study further demonstrates the robustness of DOE as a tool for developing standardized orodispersible herbal formulations.

**Keywords:** Orodispersible, Sodium starch glycolate, microcrystalline cellulose (MCC), Crospovidone, Design of experiment.

## FORMULATION AND EVALUATION OF ANTI-INFLAMMATORY TOPICAL HERBAL GEL

Kale R.N., Karne S.D., Abhang P.S., Nimbalkar R.M., Kaulge P.D.
SVPM's College of Pharmacy, Malegaon (BK) Tal- Baramati, Pune, Maharashtra 413115
ramdas.kalesvpm@gmail.com

Herbal remedies are more acceptable in the view, that they are safe with fewer side effects than the synthetic ones. Herbal formulations are in more demand in the market. Inflammatory diseases including different types of rheumatic disease are major cause of morbidity throughout the world. The present work deals with the formulation and evaluation of polyherbal Anti-inflammatory formulation containing aqueous extract of Myristica fragrance fruits, Trigonella foenum- graecum seeds, Moringa oleifera Lam leaves. Aqueous extracts of the selected plants were prepared by maceration. Prepared extracts were subjected to preliminary phytochemical screening using standard chemical tests. The gel was prepared using all extracts, polymer carbopol 934, propylene glycol, triethanolamine, propyl paraben, Jasmine oil, Alcohol, EDTA and distilled water. Prepared formulations were evaluated for various parameters like colour, appearance, consistency, viscosity , Spreadability, pH and In vitro anti-inflammatory study was carried out using inhibition of protein denaturation assay. Preliminary phytochemical screening revealed the presence of carbohydrates, proteins, alkaloids, glycosides, flavonoids, tannins and phenolic compounds in the prepared extracts. Batch D of prepared formulation showed all the evaluation parameters in acceptable limit. In vitro anti-inflammatory evaluation using the protein denaturation inhibition assay revealed 40.94% inhibition for the developed herbal gel compared to 63.28% for the marketed formulation. Statistical analysis ($p > 0.05$) indicated no significant difference between the two, suggesting that the prepared formulation exhibits anti-inflammatory potential, demonstrating comparability with the standard product and supporting its promise as an effective topical alternative.

**Keywords:** Herbal gel, Anti-inflammatory activity.

## PREPARATION AND CHARACTERISATION OF CAPECITABINE MICROSPHERES FOR COLORECTAL CANCER

Alavala Nandini and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
alavalanandini@gmail.com

ISBN: 978-81-980623-8-3

The aim of the present study was to formulate and evaluate Capecitabine microspheres for colorectal cancer and to reduce dosing frequency and improve patient compliance. Microspheres were prepared by emulsion solvent evaporation technique using polymers like ethyl cellulose (EC) and HPMC K-100 in different ratios. The prepared microspheres were evaluated for flow properties, percentage yield, drug entrapment efficiency and in vitro dissolution studies. Results showed that as the concentration of polymer ratio increases it affects the particle size, percentage yield and drug release from the microspheres. Percentage yield of F6 microspheres was found up to 95.13%. The release study was done simulated intestinal fluid (SIF - pH 7.4) for 24 hours and showed that the drug was protected from being release in the physiological environment of intestine and efficiently released in colon (95.85%). The optimized formulation F6 exhibited the drug release in sustained manner and follows zero order, non Fickian diffusion mechanism. Accelerated stability study was carried out for the optimized formulation and results showed that there were no significant changes in percentage drug entrapment efficiency, particle size and In vitro controlled release of Capecitabine. The surface morphology analysis formulation F6 showed spherical structure with smooth surface morphology. The prepared microspheres are promising drug delivery for oral sustained administration to targeting colon and provides better kinetic profile with improved bioavailability.

**Keywords:** Colorectal cancer, Microspheres, and In vitro controlled release.

## FABRICATION OF AN OPTIMIZED COLLAGEN-BASED BIOSCAFFOLDS FOR SKIN TISSUE REGENERATION BY 3D PRINTING

Vidyavathi M*, Krishna Tejaswi A, Sujatha D
Institute of Pharmaceutical Technology, Sri Padmavati Mahila Visvavidyalayam (Women's University), Tirupati 517 502, Andhra Pradesh, India
vidyavathi@spmvv.ac.in

Skin tissue engineering offers advanced solutions for chronic wounds, burns, and skin loss. Collagen-based scaffolds when integrated with 3D printing will yield precise porous architectures that greatly enhance regenerative and therapeutic outcomes. This study developed fish scales derived collagen bioscaffolds using 3D printing via pneumatic extrusion, optimized through a $3^2$ factorial design with HPMC and TCP as variables. The optimized scaffold exhibited 0.15 mm thickness, 76% swelling index, apparent density (0.018 g/cm²), porosity (98.6%), folding endurance of 261 cycles, tensile strength of 0.706 MPa, and burst resistance of 18.63 N. Biodegradation showed 16.8% after 30 days. SEM revealed interconnected pores (200–400 µm) with nano roughness, supporting cell adhesion. FTIR analyses confirmed the presence of collagen, HPMC functional groups including amide I, amide II, hydroxyl, and ether, while XRD results showed the same characteristic peaks as pure collagen, HPMC, signifying no alteration in crystallinity. DSC confirmed thermal stability fit for biomedical applications. Biological evaluations demonstrated excellent cytocompatibility, with a 262.0% increase in cell proliferation, absence of cytotoxicity, and enhanced cell migration in wound scratch assay. Antibacterial activity was confirmed with inhibition zones of 18.4 ± 2.4 mm (E. coli) and 21.9 ± 2.5 mm (S. aureus). Stability tests showed no significant changes under ambient and refrigerated storage. In vivo studies demonstrated superior wound contraction, faster re-epithelialization, and angiogenesis evidenced by CAM assay. In summary, the optimized 3D-printed collagen based scaffold exhibited strong structural, mechanical, antibacterial, and biological characteristics, positioning it as a highly promising option for wound healing and skin tissue engineering.

**Keywords:** Collagen, Bioscaffold, Skin tissue engineering, 3D printing

## FABRICATION OF AN OPTIMIZED BIOCERAMIC SCAFFOLD BY 3D PRINTING FOR SKIN TISSUE REGENERATION

Harshini M*, Vidyavathi M
Institute of Pharmaceutical Technology, Sri Padmavati Mahila Visvavidyalayam, (Women's University), Tirupati 517 502, Andhra Pradesh, India
harshinireddym15@gmail.com

Recently, 3D bioprinted scaffolds have been considered as a novel approach, aimed at replicating the intricate structure of native skin in skin tissue engineering. In this study, pneumatic extrusion-based 3D printing technique was employed to fabricate cube-shaped scaffolds. Methyl cellulose and tricalcium phosphate concentrations were optimized using a 32-factorial design approach, and combined with a constant collagen concentration to maximize the swelling index and porosity, while minimizing thickness and apparent density. An optimized blank scaffold was incorporated with varying concentrations of Bredigite (1%, 2%, and 3%) to fabricate bioceramic scaffolds. Bioceramic scaffolds exhibiting the presence of hydroxyl, Si–O stretching in FTIR, along with improved crystallinity due to functionalization effects in XRD, and an increase in DSC enthalpy of 9.87 mJ. SEM with EDS images revealed a highly porous, rough-surfaced scaffold composed of calcium, silicon, and magnesium.The tensile strength of 3% bioceramic scaffold significantly increased from 0.64±0.04 MPa to 1.94±0.06 MPa, burst strength improved from 7.85±0.21N to 21.58±0.11N, and antibacterial activity was enhanced considerably against Streptococcus and E. coli. Furthermore, in the MTT assay, a higher cell proliferation of 393.6±2.07% and substantially lower cytotoxicity were observed, along with increased angiogenesis in the CAM assay. In vivo experiments demonstrated significant wound contraction over 28 days, accompanied by full-thickness wound assessment. The short-term stability studies confirmed the stable thickness, density, swelling index, and porosity at ambient and refrigerator temperatures. Overall, this study highlighted that these scaffolds offer a mechanically stable framework for wound healing by speedy regeneration of the skin tissue.

## DEVELOPMENT OF NOVEL BIODEGRADABLE VAGINAL CUP FOR THE TREATMENT OF VULVOVAGINAL CANDIDIASIS

Dr. Rupalben K. Jani1
Parul Institute Of Pharmaceutical Education And Research, Department Of Pharmaceutics, Faculty of Pharmacy, Parul University.
Limda, Waghodia, Vadodara, Gujarat-391760.

The common fungal infection known as vulvovaginal candidiasis (VVC), which is mostly caused by Candida species, causes severe pain and repeated infections in those who have it. Conventional antifungal therapies frequently have systemic adverse effects, low retention times, and limited absorption. With a number of benefits, including localized action, less systemic adverse effects, and increased bioavailability, vaginal medication administration is a focused and efficient method of delivering therapeutic compounds straight to the vaginal mucosa. When it comes to treating infections, hormone imbalances, and contraceptive uses, the vaginal method is very helpful. Its porosity and abundant blood flow create an ideal setting for medication absorption. To improve medication retention and prolong release, a variety of dosage forms have been created, such as gels, creams, pills, vaginal rings, and bioadhesive drug delivery systems. Available dosage forms issues including mucosal irritation, pH fluctuation, and enzymatic degradation must be resolved. The efficiency and patient compliance of vaginal medicines are being enhanced by developments in controlled-release formulations and polymer-based drug delivery methods. In order to overcome these obstacles, the goal of this study is to develop a vaginal cup for the treatment of VVC that is made of gelatin, gellan gum, and hydroxypropyl methylcellulose (HPMC K4M) as polymers and glycerol was added to improve mechanical strength. The casting method was used to prepare dosage form. As an API the posaconazole the powerful broad-spectrum triazole antifungal was incorporated into the formulation, Physical-chemical characteristics, drug content, and in-vitro antifungal activity were all evaluated for the produced formulation. The vaginal cup formulation was optimized using 32 full factorial design, resulting in an optimized batch with an in-vitro drug release 93.12±0.66 %, folding endurance 154±1.62 folds, drug content 92.37±0.17 %. The results highlight that the potential of posaconazole loaded biodegradable vaginal cup as an optimal targeted drug delivery method for the treatment of VVC, offering a promising approach to improving therapeutic outcomes while reducing systemic exposure.

**Keywords:** vulvovaginal candidiasis, vaginal medication delivery, vaginal cup, posaconazole, 32 full factorial design.

**MICRONEEDLE-MEDIATED DELIVERY SYSTEMS FOR PROTEINS AND PEPTIDES: A PAINLESS AND EFFICIENT APPROACH**

Avinash Verma
Rungta College of Pharmaceutical Sciences and Research ,Raipur, Chhattisgarh, India - 492099.
avinashverma210405@gmail.com

Proteins and peptides are highly effective therapeutic agents, but their clinical use is often limited by poor oral bioavailability and the invasiveness of conventional injections. Microneedle (MN) technology has emerged as a minimally invasive, painless, and patient-friendly alternative for protein and peptide delivery. MNs penetrate the stratum corneum without reaching pain receptors, allowing efficient transdermal transport of biomolecules while avoiding enzymatic degradation. Different types of microneedles, including solid, coated, dissolving, hydrogel-forming, and hollow systems, have been developed using biocompatible materials. Preclinical and clinical studies demonstrate successful delivery of insulin, vaccines, and hormones with enhanced stability, reduced storage requirements, and improved patient compliance. Overall, microneedle-mediated systems offer a promising platform for next-generation therapeutic delivery, with potential applications in chronic disease management, vaccination, and regenerative medicine.

**Keywords:** Microneedles, Protein delivery, Peptide therapeutics, Transdermal drug delivery, Controlled release

**"A REVIEW ON TRANSFEROSOME- BASED TOPICAL DRUG DELIVERY: A NOVEL STRATEGY FOR RHEUMATOID ARTHRITIS MANAGEMENT "**

Sandhya Maurya*, Rashmi Sahu, Ankita Bhaduri, Bina Gidwani
Columbia Institute of Phamacy, Raipur, Chhattisgarh
sandhya121maurya@gmail.com

Arthritis is a chronic autoimmune disorder which is characterized by a chronic inflammation of synovium and severe joint destruction. After a vast study and development in the field of arthritis, the disease is still incurable. The conventional treatment methods suffer from poor bioavailability, and severe adverse effects. Hence RA requires rapid onset of action for immediate pain relief and delivery of drug directly to the site of action. Transferosomes also known as the "the ultra flexible lipid vesicles" can resolve these drawbacks by making the drug available directly to the affected site of the body. Transferosomes can accommodate drug molecules with wide range of solubilities and facilitate topical delivery of low as well as high molecular weight drugs. Transferosomes can deform and pass through narrow constriction (from 5 to 10 times less than their own diameter) without measurable loss and provide better penetration of intact vesicles. This review highlights the importance of transferosomal system for the treatment of the rheumatoid arthritis from topical route.

**Keywords:** Transferosome, autoimmune disorder, rheumatoid arthritis

**"GELATIN-FREE CAPSULES: A MODERN APPROACH"**

Vedant Madankar, Ruchi Khobragade, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee
vedantmadankar70@gmail.com

The pharmaceutical industry is witnessing a paradigm shift toward sustainable and patient-friendly dosage forms.Traditionally, capsules have been manufactured using gelatin derived from animal sources,which raises concerns regarding dietary restrictions, cultural preferences, and environmental sustainability. Two-piece capsules have been used for almost a century in the pharmaceutical field, and gelatin has been adopted as the main material of these capsules due to its excellent characteristic as a thickener. The gelatin dissolves under high concentration into water of a high temperature and quickly gels in room temperature. The thickness of the film made by the gelatin becomes uniform. The crosslinking of gelatin and drug incompatibilities and the strict regulations regarding the use of animal derived gelatin requiring the absence of transmissible spongiform encephalopathy (TSE) have encouraged the search for gelatin replacement. To replace gelatin, Artificial Intelligence (AI) is playing a transformative role in the development of gelatin-free capsules. By leveraging data-driven insights, AI enables the identification and optimization of plant-based polymers such as hydroxypropyl methylcellulose (HPMC), pullulan, and seaweed-derived polysaccharides. AI algorithms accelerate material screening, predict capsule stability, simulate drug release behavior, and reduce formulation costs. Furthermore, AI integrates with advanced manufacturing technologies, including 3D printing, to design personalized capsule systems with precise disintegration and dissolution profiles. This innovative approach not only ensures broader patient compliance but also promotes eco-friendly practices in pharmaceutical manufacturing. Thus, AI in action is redefining capsule technology by enabling safer, sustainable, and consumer acceptable gelatin-free alternatives.

**BRAIN-TARGETED DELIVERY OF VENLAFAXINE VIA SERUM ALBUMIN NANOPARTICLES: PREPARATION AND CHARACTERIZATION**

J. Josephine Leno Jenita* and Namratha V
Department of Pharmaceutics, College of Pharmaceutical Sciences, Dayananda Sagar University, Devarakaggalahalli, Harohalli, Kanakapura Road, Bengaluru South, Karnataka 562112, India

Most of the antidepressants available on the market for the management of depression are available through the oral route of administration and also have several drawbacks. The most innovative and adaptable class of delivery methods, nanoparticles can be used to deliver therapeutic medicines to a specific target site in a regulated manner and as both diagnostic and therapeutic agents. The purpose of the present study was to develop nano-based formulations of Venlafaxine for the management of depression. Different batches of venlafaxine-loaded serum albumin nanoparticles were prepared using the desolvation technique, with varying polymer concentrations. Amongst the six batches of nanoparticles, V4 was found to be ideal by considering its drug loading percentage of 32.57±0.51%w/w along with the yield of 94.89±0.2% w/w, the particle size of 194± 1.2nm with the polydispersity index of 0.375 ± 0.8 and zeta potential of -27.1mV. In vitro drug release showed a biphasic pattern with initial burst release and later sustained release (23.78% w/w to 84.94% w/w after 24 h) following the Fickian diffusion-based release mechanism based on release kinetics ('n' values from the Korsmeyer-Peppas were ranged from 0.0804 to 0.2676). The formulation V4 was incorporated into thermosensitive gelling systems called in situ gels to enhance the drug delivery to the specific target site. Ex vivo drug diffusion studies were conducted on freshly excised goat nasal mucosa with a Franz diffusion cell simulated nasal fluid for all three formulations up to 8h, and the in-situ gel showed 89% drug release. The targeting efficiency of VLF-BSA NPs incorporated in situ gel was compared with nanoparticles. Drug solution was administered through the nasal route to determine the antidepressant activity through the forced swim test.

**Keywords:** Venlafaxine, Serum Albumin, Nanoparticles, Thermosensitive gels, Anti-depressant

**DESIGN AND DEVELOPMENT OF HYALURONIC ACID SURFACE MODIFIED ASTAXANTHIN LOADED CHITOSAN NANOPARTICLES FOR ENHANCED ANTI- TUMOUR EFFICACY IN HEPG2 CELLS**

Deepavarchini Prakash*, Dhanasekar Jayakumar
Department of Pharmaceutics, Vivekanandha Pharmacy College for Women, Sankari, Salem, Tamil Nadu, India – 637303
deepavarchini@gmail.com

Astaxanthin (AST), a potent antioxidant with reported anticancer activity, suffers from poor aqueous solubility and limited stability, restricting its therapeutic applications. In this study, astaxanthin was encapsulated in hyaluronic acid (HA)-surface-modified chitosan-based nanoparticles to enhance stability, bioavailability, and tumor-targeting potential. Nanoparticles were formulated using chitosan, soya lecithin, TPGS, and HA through molecular self-assembly, followed by high-pressure homogenization and centrifugation at 19,000 rpm for 60 min, yielding three formulations (F1–F3). Physicochemical characterization included particle size, polydispersity index (PDI), zeta potential, SEM, and XRD analyses. Astaxanthin exhibited very low water solubility, moderate

ISBN: 978-81-980623-8-3

solubility in methanol and ethanol, and high solubility in DMSO, with a melting point of 210 °C, confirming thermal stability. FTIR and DSC analyses indicated no significant interactions between the drug and polymer matrix, demonstrating compatibility. UV spectroscopy confirmed purity with λ_max at 491 nm (HCl) and 495 nm (phosphate buffer). Formulation F1 exhibited optimal properties, with a mean particle size of 110.6 nm, PDI 0.282, zeta potential 32.0 mV, drug content 84.43 ± 1.15%, and entrapment efficiency 75.15%, indicating uniform dispersion and good stability. In vitro drug release studies showed F1 released 95.14 ± 1.15% of astaxanthin in phosphate buffer, compared to 25.18% from free drug, demonstrating significantly enhanced release. Cytotoxic evaluation against HepG2 liver cancer cells via the MTT assay (570 nm) confirmed potent anticancer activity. These results suggest that HA-modified chitosan nanoparticles provide a promising platform for improving astaxanthin's stability, controlled release, and therapeutic efficacy, highlighting their potential for targeted anticancer applications.

**Keywords:** Astaxanthin; Chitosan; Hyaluronic acid; Anti-tumour activity

## FORMULATION AND EVALUATION OF NIOSOMAL HERBAL HAIR SERUM USING ALKANET ROOT EXTRACT

A.Rajashri, S.Thanushiya
Department of Pharmaceutics, Pallavan Pharmacy College, Kanchipuram, Tamil Nadu, India
631502
rajashrianbu2003@gmail.com

In recent years, hair-related problems have become an important source of stress and depression for many individuals, mainly driven by factors such as genetics, hormonal changes, environmental effects, and the use of chemical hair products. The purpose of this research paper is to evaluate a herbal hair serum using Alkanet tinctoria root extract with various natural ingredients to solve the prevalent hair problems. The alkanet root is a natural component that has several possible benefits with a rich history of traditional use. It is rich in alkannin and shikonin, which promote hair growth and have many other medicinal activities. In recent times, herbal formulations have become more popular due to their fewer side effects. More popularly, hair serum is preferred by many people due to its mild and non-disintegrating nature over hair oil. Herbal hair serum has been developed with a focus on promoting hair growth, enhancing management, and reducing the side effects associated with chemical options. Formulation involves Niosome, in which active ingredients are encapsulated to improve the delivery and efficacy of active ingredients. The niosomal incorporation of the alkanet root extract in a herbal serum greatly improves its stability and bioavailability, providing a promising natural option for hair care. Herbal hair serum is evaluated through physical appearance, viscosity, skin irritation test, and antimicrobial efficacy against Malassezia globosa, demonstrating promising results, indicating that the prepared serum is safe and effective for daily use.

**Keywords:** Alkanet Tinctoria, Hair serum, niosome, Hair growth, Herbal formulation.

## ROLE OF 3D PRINTING IN PHARMACEUTICAL DRUG DEVELOPMENT

Ameya Joshi 1*, Rajeshwari Bhagat 1, Gargi Dewangan 1 Shiv Shankar Shukla 1
Columbia Institute of Pharmacy, Raipur, (C.G.)
ameyajoshi46@gmail.com

The advent of 3D printing technology has heralded a transformative era in various sectors, including the pharmaceutical industry. This review paper explores the pivotal role of this technology in pharmaceutical drug development, offering a comprehensive analysis of its applications, benefits, challenges, and future prospects. 3D printing, or additive manufacturing, has demonstrated significant potential in revolutionizing drug formulation and production by enabling the precise fabrication of complex drug geometries, personalized dosages, and multi-drug combinations with controlled release characteristics. The technology allows for the creation of dosage forms that are specific to individual patient needs, potentially improves efficacy, patient compliance, and therapeutic outcomes of the drug. Additionally, 3D printing presents opportunities for rapid prototyping and innovation in drug design, reducing development times and costs. However, the integration of 3D printing into pharmaceutical manufacturing also poses regulatory, technical, and ethical challenges that need to be addressed to fully leverage this technology's potential. This paper reviews the current state of these technologies in drug development, including fused deposition modelling, stereolithography, and selective laser sintering, among others. It discusses their implications for personalized medicine, the regulatory landscape, intellectual property issues, and the environmental impact of pharmaceutical manufacturing. Moreover, the paper outlines the future directions emphasizes the need for interdisciplinary collaboration, standardization, and regulatory frameworks to foster innovation while ensuring patient safety and product quality. Through this review, the transformative potential of three - dimensional printing in pharmaceutical development of drug, marking shift towards more personalized, efficient, and sustainable drug manufacturing processes are highlighted.

**Keywords:** 3D printing technology, transformative era, pharmaceutical drug development, additive manufacturing, personalized medicine.

## NOVEL CAPSULE IN CAPSULE FORMULATION

Rizwan Pathan
Department of Pharmaceutics, Mumbai University, Mumbai, Maharashtra, India
pathan75rizwan@gmail.com

Fungal infections continue to pose a major therapeutic challenge, particularly with the rise of drug resistance and patient non-compliance due to side effects of conventional antifungal drugs. Itraconazole, a broad-spectrum triazole antifungal agent, is effective against systemic and superficial fungal infections but often causes gastrointestinal disturbances, including dysbiosis and constipation, during prolonged therapy. To address these limitations, the present project focuses on capsule-in-capsule formulation combining Itraconazole with Triphala, a traditional Ayurvedic formulation composed of Terminalia chebula, Terminalia bellirica, and Emblica officinalis. Triphala is recognized for its antioxidant, anti-inflammatory, gut-regulating, and prebiotic activities, which may counteract the gastrointestinal side effects of Itraconazole and improve therapeutic acceptability. The inner capsule will be loaded with Itraconazole, ensuring controlled antifungal release, while the outer capsule will contain Triphala to support gut health and restore intestinal balance. The formulation will be evaluated for physicochemical properties, compatibility, in vitro dissolution, and antifungal efficacy against selected fungal strains using zone of inhibition and minimum inhibitory concentration assays. Additionally, intestinal gut motility studies will be performed to determine the protective effect of Triphala on bowel regularity and to validate its supportive role in minimizing Itraconazole-induced gastrointestinal discomfort. By integrating modern antifungal therapy with a time-tested herbal formulation, this study aims to create a safe, effective, and patient-compliant antifungal dosage form. The expected outcome is a dual-benefit capsule that not only enhances antifungal activity but also promotes gastrointestinal well-being.

**Keywords:** Capsule-in-capsule, Itraconazole, Triphala, antifungal therapy, gut motility, synergistic effect

## FORMULATION AND EVALUATION OF GANCICLOVIR FLOATING CONTROLLED DRUG DELIVERY SYSTEM

Sarath Kumar S.J 1, G Alagu Manivasagam
Department of Pharmacy, Annamalai University, Chidambaram, Tamil Nadu-608001
sarathkumarsj123@gmail.com

Oral controlled release dosage form has been developed over the past three decades due to their considerable therapeutic advantages such as ease of administration, patient compliance and flexibility in formulation. One of the most feasible approaches for achieving a prolonged predictable drug delivery profile is floating drug delivery system (FDDS) which prolongs the gastric residence time and increases the overall bioavailability of the dosage form. In this study the Ganciclovir is formulated as a floating tablet. 4 formulations were prepared. In each formulation drug concentration remains the same and excipient concentration was varied. Direct compression method was used for the formulation. Different polymers such as HPMC K 15, HPMC K 100, MCC were used with other standard excipients. Sodium bicarbonate was used

ISBN: 978-81-980623-8-3

as effervescent agent. The prepared powder blend was evaluated for its preformulation characteristics viz, true density, bulk density, compressibility index, angle of repose, Hausner's ratio.The physical characters of tablet were evaluated viz, hardness, friability, weight variation, thickness, drug content, swelling study, floating time and in vitro dissolution analysis. The results of preformulation study showed that the prepared powder blend had good flow property and packaging ability. The results of hardness and friability test revealed that all the twelve formulation F1 to F4 showed good mechanical strength and complied with pharmacopoeial specifications. Optimized formulation F3 showed a drug release of 97.55±1.53 % and a floating lag time of 2.92 min and total floating time of >15 h clearly complies with the standard values. Overall results showed that the formulation satisfies the parameters necessary for a good floating drug delivery system. The results of the present study clearly stipulate the feasibility to develop Ganciclovir in the form of gastroretentive drug delivery system with prolongation of gastric retention time and controlled drug release.

**Keywords:** Ganciclovir, Floating time, Floating tablets, Swelling index

**OPTIMIZATION AND CHARACTERIZATION OF FLAX SEED MUCILAGE-BASED IMMEDIATE RELEASE TABLET FORMULATION**

Rushikesh Dabhade
Department of Pharmaceutical Sciences, MIT-WPU, Pune, Maharashtra, India-411038.
rushidabhade720@gmail.com

In tablet formulations, pharmaceutical excipients are essential, and natural sources are becoming more and more popular because of their accessibility, affordability, and safety. In senna-based immediate release tablets, flaxseed mucilage (FSM), a hydrocolloid high in polysaccharides, was assessed as a possible natural binder and disintegrant. Following its extraction, characterization, and determination of its physicochemical properties (pH 6.4, swelling index 53.84%), FSM was shown to be suitable for gastrointestinal disorders. Different FSM concentrations were used to generate the formulations, which were then compared to starch as a standard binder. With a hardness of 7.2 kg/cm2, a disintegration time of 5.1 minutes, and a total drug release of 99.81% within 60 minutes, the optimized formulation (F5), which contained 4% FSM and 10% starch, outperformed the other factorial design batches. These findings suggest that FSM not only had sufficient binding qualities but also made a substantial contribution to quick breakdown and effective drug release. Similar results were obtained from comparison research with the commercially available senna tablet (Senasof), which demonstrated a hardness of 8.0 kg/cm2, disintegration in 6 minutes, and 99.03% drug release at 60 minutes. This proves that FSM is a good natural substitute for artificial binders. The study demonstrates that flaxseed mucilage can be effectively used as a natural excipient in immediate-release laxative pills because of its swelling capability and advantageous physicochemical profile. Its performance, which is on par with a commercial product, shows that it can either supplement or replace traditional binders and disintegrants in medicinal formulations.

**Keywords:** Flaxseed mucilage, natural excipients, senna, immediate release tablets, laxative.

**PC-579**

**FORMULATION DEVELOPMENT AND CHARACTERIZATION OF SUSTAINED RELEASE EFFERVESCENT FLOATING AND FLOATING ADHESIVE BILAYERED TABLETS OF EZETEMIBE-NATEGLINIDE AND GEMFIBROZIL-NATEGLINIDE**

Dr.MD.Parveen,
Browns college of Pharmacy, khammam, Telangana.

A major constraint in oral controlled release drug delivery system (CRDDS) is that not all drug candidates are absorbed uniformly throughout the GIT. Some drugs are absorbed in a particular portion of the GIT only or are absorbed to a different extent in various segments of the GIT. Such drugs are said to have an absorption window, which identifies the drugs primary site for absorption in the GIT. Drugs having site-specific absorption are difficult to design as oral CRDDS because once the drug is released after crossing the absorption window, the released drug goes to waste with negligible or no absorption. This phenomenon drastically decreases the drugs bioavailability. In this situation, design of CRDDS is to be modified in such a way that it has more residence time in stomach to release the drug before the absorption window. Bilayer tablets are prepared with different drugs, these two drugs are released at a time. This type of design is called as bilayered gastroretentive drug delivery system (GRDDS) and provides the better absorption. In this research work, nateglinide, ezetimibe and gemfibrozil were selected as model drugs. Nateglinide is an aminoacid derivative that induces an early insulin response to meals decreasing postprandial blood glucose levels which act by binding to β cells of the pancreas to stimulate insulin release. Ezetimibe is a lipid-lowering compound that inhibits intestinal cholesterol and phytosterol absorption. Gemfibrozil is used with diet changes (restriction of cholesterol and fat intake) to reduce the amount of cholesterol and triglycerides in the blood in certain people with very high triglycerides who are at risk of pancreatic disease. All the tablets were prepared by direct compression method. The prepared tablets were evaluated for their pre-compression characters (equilibrium solubility study and acid stability study of the drug, bulk density, tapped density, compressibility index, angle of repose and drug-excipient compatibility study) and post-compression characteristics such as hardness, thickness, weight variation, friability, drug content, in vitro buoyancy, in vitro dissolution studies, swelling studies, bioadhesive studies, stability studies, in vivo radiological and bioavailability studies in human volunteers.

**Keywords:** Constraint, Post prandial, buoyancy, bioadhesive, bioavailability.

**FORMULATION AND EVALUATION OF HERBAL PATCH FOR SYMPTOMATIC TREATMENT OF VARICOSE VEINS**

Renugadevi Poovarajan
Department of Pharmaceutics,HK College of Pharmacy, Mumbai, Maharashtra, India-400102
renugadevi.poovarajan_24-26@hkcp.edu.in

Varicose veins are a prevalent chronic venous disorder characterized by dilated, tortuous superficial veins, resulting in pain, swelling, and heaviness that impair quality of life. Current treatment options, including surgery and minimally invasive procedures, are costly, invasive, and unsuitable for patients such as pregnant women or individuals with diabetes who are at higher surgical risk. Conventional oral and topical pharmacotherapies provide only partial relief due to poor dermal penetration and bioavailability. This study focused on the development and evaluation of a herbal nanoemulsion-based transdermal patch designed for symptomatic relief of varicose veins. The formulation incorporated venotonic, anti-inflammatory and analgesic. A nanoemulsion was prepared using high-energy emulsification, yielding a droplet size <100 nm and low polydispersity index, ensuring stability and efficient transdermal delivery. The optimized nanoemulsion was incorporated into a patch and evaluated for mechanical strength, drug content uniformity, ex vivo skin permeation, and release kinetics. Results demonstrated improved dermal permeation and sustained drug release. Skin irritation studies confirmed good dermal safety. Overall, the developed herbal nanoemulsion patch provides a non-invasive, cost-effective, and patient-compliant alternative for managing varicose vein symptoms. Its use is particularly advantageous for pregnant women and diabetic patients who cannot undergo surgical intervention, offering enhanced therapeutic outcomes through synergistic analgesic, anti-inflammatory, and venotonic effects.

**Keywords:** Varicose veins, herbal, patch, venotonic, anti-inflammatory

**PC-581**

**FORMULATION AND EVALUATION OF A HERBAL ANTIMICROBIAL CREAM WITH OPTIMIZED TOPICAL PROPERTIES AND THERAPEUTIC POTENTIAL**

Vedant Kamlakar Shaligram[1], Madhuri U Shelar[1], Nutan V Nibe[2]
[1]Department of Pharmaceutical Quality Assurance, Alard School of Pharmacy, Pune – 411057, India
[2]Department of Pharmaceutical Chemistry, Trinity College of Pharmacy, Pune – 411048, India
shaligramvedant8@gmail.com

This study focused on formulating and evaluating a herbal antimicrobial cream containing ethanolic extracts of Curcuma longa (curcumin) and Glycyrrhiza glabra (glycyrrhizin). Three optimized batches (F1, F2, F3) were prepared with excipients including sesame oil, coconut oil, white

ISBN: 978-81-980623-8-3

beeswax, and linoleic acid. Among these, batch F3 showed superior physicochemical properties and was selected as the most effective. The prepared cream exhibited desirable characteristics, including a smooth, non-greasy appearance, homogeneity, skin-compatible pH (6.21), suitable spreadability (9.33 g·cm/sec), and viscosity with pseudoplastic rheology, ensuring ease of topical application and skin compatibility. Permeation of actives was confirmed by Franz diffusion studies. Antimicrobial efficacy was assessed by the disc diffusion method, where filter paper discs impregnated with the formulation were placed on agar plates inoculated with standardized microbial cultures; zones of inhibition measured 20 mm against Escherichia coli, 18 mm against Staphylococcus aureus, and 15 mm against Candida albicans, demonstrating broad-spectrum activity. The formulation remained stable without phase separation during evaluation. This synergistic cream, enhanced by functional excipients like sesame oil, offers a promising natural alternative for microbial skin infections. Future studies may explore its potential anticancer activity to broaden therapeutic applications.

**Keywords:** Curcumin, Glycyrrhizin, sesame oil, herbal cream, antimicrobial activity, topical formulation, anticancer potential

## FORMULATION AND EVALUATION OF FAST DISSOLVING TABLETS BY NANOCRYSTAL TECHNOLOGY FOR POORLY WATER-SOLUBLE DRUG

Irene Nethala and R.L.C. Sasidhar
Department of Pharmaceutics, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences, Chowdavaram, Guntur, Andhra Pradesh
irenenethala@gmail.com

This study focuses on the development of nanocrystal (NC) based fast dissolving tablets (FDTs) of Valsartan to enhance its solubility, dissolution, and bioavailability. Valsartan, a poorly water-soluble antihypertensive drug, was successfully processed into nanocrystals using the solvent-antisolvent precipitation method, optimized through a $2^3$ factorial design by varying stabilizer concentration, solvent to antisolvent ratio, and stirring speed. The prepared nanocrystals exhibited significantly higher saturation solubility than the pure drug due to reduced particle size. FDTs containing 20 mg of Valsartan nanocrystals were formulated via direct compression using 341roscarmellose sodium (CCS) and sodium starch glycolate (SSG) as superdisintegrants. Pre compression and post compression evaluations confirmed excellent flow properties, mechanical stability, and compliance with pharmacopeial standards. Among the six formulations, F3, containing 20 mg of CCS, demonstrated the shortest disintegration time (10.6 seconds) and the highest drug release (95.02% within 12 minutes). These findings highlight the potential of nanocrystal-based FDTs in improving Valsartan's bioavailability and addressing limitations associated with conventional tablet formulations, offering a promising alternative for better patient compliance and therapeutic efficacy.

**Keywords:** Nanocrystals, (NC), Fast Dissolving Tablets (FDTs), Solubility, Dissolution, Direct compression and Antihypertensive Drug.

## DEVELOPING AND STANDARDIZING SUSTAINED RELEASE METFORMIN HYDROCHLORIDE TO PREVENT DIABETES

Awdhut Pimpale and Priyanka Waghmare
Tulsiramji Gaikwad Patil College of Pharmacy, Maharashtra, India – 441108
adityapimpale@gmail.com

Double layered solid dosage form used for internal purpose. It is double layered one is sustained release and other is immediate release. This research manages formulation of bilayer tablet of Metformin Hydrochloride used for slow drug releasing layer. Lab based studies of sustained release was performed and release profile of Lot L6 containing 40% concentration of HPMCK100 was best compared to other five formulations. As there is increment in polymer concentration then release time also rises. Metformin hydrochloride is a first choice of drug as it fallen both basal as well as post elevated blood sugar level in patient with insulin independent diabetes. Since it lowers the plasma glucose without affecting insulin secretion. HPMCK100 shows release up to 12hrs. at higher concentrations with other polymer xanthum gum. According to the n value of Koreseyer, the drug release kinetics of sustained release formulation match the Higuchi model, and Peppas's model appears to be a complex process of swelling and diffusion with zero order kinetics. Based on the solubility criteria of BCS different drug can be incorporated in bilayer drug delivery system to improve their bioavailability and to reduce the dose of drug with reduction in frequency of administration.

**Keywords:** Double layered, Metformin hydrochloride, Xanthum gum, Plasma glucose, solubility.

## QUALITY BY DESIGN-BASED FORMULATION AND EVALUATION OF GASTRORETENTIVE FLOATING TABLETS OF TRAMADOL HYDROCHLORIDE

Asish Sahu, Moonmun Dhara, Anjan Kumar Mahapatra
Royal College of Pharmacy and Health Sciences, Berhampur, 760002, Odisha, India
anjanmahapatra@gmail.com

The present study aimed to design and develop gastroretentive floating tablets of tramadol hydrochloride using a Quality by Design (QbD) approach to enhance gastric residence time and achieve sustained drug release. Floating tablets were prepared by direct compression using hydrophilic polymers such as xanthan gum, HPMC K100M CR, and their combinations. Preformulation studies including IR and DSC confirmed drug–excipient compatibility. A factorial design under QbD principles was employed to identify critical formulation variables influencing buoyancy and drug release. Prepared formulations were evaluated for buoyancy lag time (BLT), total floating time (TFT), dissolution, and drug release kinetics. Among the formulations, batch F8 (HPMC K100M CR 15% + xanthan gum 10% of tablet weight) exhibited optimized performance with >90% sustained release, BLT of 10 seconds, and TFT of over 24 hours. The release kinetics followed non-Fickian diffusion (n = 0.605), indicating combined diffusion and erosion mechanisms. Accelerated stability studies at 40 ± 2 °C/75 ± 5% RH for 30 days showed no significant changes in drug content or floating properties, confirming formulation stability. The optimized formulation demonstrated prolonged gastric retention, rapid buoyancy, and controlled drug release, making it a promising gastroretentive drug delivery system. The application of QbD provided a systematic framework for robust formulation development of tramadol HCl floating tablets.

**Keywords:** Quality by Design (QbD), gastroretentive system, floating tablets, sustained release, stability.

**PC-585**

## DEVELOPMENT OF 3D PRINTED BIODEGRADABLE MICRONEEDLES WITH PARACETAMOL LIPOSOMES; A NOVEL APPROACH FOR THE ANTI PYRETIC EFFECT

Lathika S & Kavinkumar M C
Department Of Pharmaceutical Chemistry Vellalar College Of Pharmacy, Thindal , Erode-638012
Lathika632713@Gmail.Com

The study aimed for the development of biodegradable 3D-printed microneedles with Paracetamol liposomes , a novel approach for the Antipyretic effect. The term 'Transdermal delivery' refers to the diffusion of a solute through the different layers of the skin to reach the systemic circulation and elicit a therapeutic effect. Microneedles are micron scaled medical devices. Microneedles are prepared using 3D printed microneedle fabrication method and the pure Paracetamol and Paracetamol liposomes were prepared and loaded into microneedle.The biocompatibility and safety of the Pure Paracetamol-loaded microneedles and Paracetamol liposome-loaded microneedles were evaluated through invitro and invivo studies to assess their efficacy in delivering anti-inflammatory and antipyretic effect were performed. Pure paracetamol loaded microneedles decreased temperature from 31.56°C to 29.10°C at 45 minutes , 28.70°C at 60 minutes , and 28.40°C at 120 minutes and Paracetamol liposomes loaded microneedles dropped the temperature from 31.56°C to 29.30°C at 45 minutes , 28.50°C at 60 minutes and 28.00°C at 120 minutes The study demonstrates that both pure paracetamol-loaded microneedles and paracetamol liposome-loaded microneedles are effective in inducing a significant reduction in rectal temperature, particularly the paracetamol liposome loaded Microneedle is one of the most effective treatment for producing the Antipyretic effect.

**DEVELOPMENT & CHARACTERIZATION OF HERBAL NIOSOMES FROM COSTUS IGNEUS LEAVES FOR MANAGEMENT OF DIABETES**

Dr. Vrunda V. Shah*, Ms. Krishna Vaghela
Dept. of Pharmacognosy, Parul Institute of Pharmaceutical Education and Research, Parul university, Vadodara, Gujarat- India-391760
varundazalavadiya@gmail.com

Diabetes mellitus is a chronic condition characterized by high blood glucose levels. The prevalence of type 2 diabetes is increasing due to factors like obesity and decreased physical activity. Diabetes can lead to serious complications such as end-stage renal disease, ischemic heart disease (IHD), and blindness. While there are treatments available to manage diabetes, there is currently no permanent cure. However, research has shown that certain plant extracts from medicinal plants & their novel formulations have anti-diabetic properties and can potentially improve the function of pancreatic beta cells. Costus igneus, commonly known as insulin plant in India, belongs to the family Costaceae. Consumption of the leaves are believed to lower blood glucose levels, and diabetics who consumed the leaves of this plant did report a fall in their blood glucose levels. The purpose of this study is to develop novel herbal formulation from Costus igneus leaves and evaluate it for either improved its ability to treat or prevent diabetes & compare with activity of plant extract. Niosomes from the extracts was developed, standardized, and tested for comparative antidiabetic study in an in- vitro assay using alpha amylase and in vivo assay by Oral Glucose Tolerance Test (OGTT) on four groups of female Albino Wistar rats. Results were compared for formulated niosomes and conventional extract of Costus igneus leaves.

**Keywords:** Costus igneus, diabetes, niosome, novel herbal formulation

4 Principal, Sandip Foundation's, Sandip Institute of Pharmaceutical Sciences, Mahiravani, Nashik – 422213.

The COVID-19 pandemic reminded us how quickly infections can spread through the air, especially in closed spaces. While chemical air disinfectants are widely used, they often bring side effects such as irritation, toxicity, and environmental damage. This has created a need for safer, natural solutions. Our work focuses on creating a herbal air vapourizer that can fight both bacteria and viruses while being safe and eco-friendly for daily use. We selected well-known medicinal plants and prepared their extracts and used to make a vapourizer formulation, which was then tested for its ability to stop harmful bacteria (S. aureus and E. coli) and to reduce viral activity in lab conditions. The herbal vapourizer successfully reduced bacterial growth and also showed encouraging antiviral effects. It proved to be safe, environmentally friendly, and left behind no harmful residues. This herbal vapourizer offers a natural and sustainable way to keep indoor air healthier. With its antibacterial and antiviral action, it could help lower the risk of airborne infections and support cleaner air in a post-COVID world.

**Keywords:** COVID-19, Herbal vapourizer, Antibacterial, Antiviral, Natural air disinfectant

**PC-588**

**DEVELOPMENT AND EVALUATION OF ROFLUMILAST SOLID DISPERSION FAST DISSOLVING TABLETS**

Muvvala Sai Likhitha and Sadhu Venkateswara Rao
Department of Pharmaceutics,Vijaya Institute of Pharmaceutical Sciences for Women Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
likhithamuvvala@gmail.com

The main objective of the present investigation was to formulate and evaluate fast dissolving tablets of roflumilast solid dispersions using direct compression method. Roflumilast solid dispersions were prepared by solvent evaporation as well as melting method. Roflumilast is a selective, long-acting inhibitor of the enzyme PDE-4 and has anti-inflammatory effects. It is used orally in the treatment of chronic obstructive pulmonary disease (COPD). Roflumilast drug belongs to BCS Class II drugs that have low solubility and high permeability. The current research work was focused to improve the aqueous solubility of roflumilast using solid dispersion technique and enhance the dissolution rate. Based on results of solubility analysis, phosphate buffer pH 6.8 was chosen as the dissolution medium. The powder blend of roflumilast solid dispersions was evaluated for flow characteristics. The fast-dissolving tablets of rolfumilast solid dispersions were subjected to post compression parameters such as weight variation, hardness, thickness, friability, drug content, wetting time, water absorption ratio, in vitro dispersion time and in vitro disintegration time and the results were found to be within the acceptable limits. Based on FT-IR spectra obtained, it was evident that there was no significant interaction of roflumilast with carriers and other excipients. From the results of dissolution study, SD1 and SD18 formulations were considered as best formulations.

**Keywords:** Solid dispersions, fast dissolving tablet, roflumilast, solvent evaporation, melting method.

**PC-589**

**FORMULATION OF A MUCOADHESIVE BUCCAL FILM OF SAROGLITAZAR WITH NATURAL BIOENHANCERS FOR ENHANCED PERMEABILITY AND PATIENT COMPLIANCE**

Dona Satya Sriharsha Aradadi and Ramakrishna Gummadi
Department of Pharmaceutical Sciences, School of Pharmacy, Aditya University, Surampalem, Kakinada -533437
donasatya79@gmail.com

This study describes the design and assessment of a mucoadhesive buccal film incorporating Saroglitazar, an antidiabetic drug classified under BCS Class III. Although Saroglitazar is highly soluble, its therapeutic utility is limited by poor permeability. To address this, buccal films were prepared to improve absorption and simplify administration. Hydroxypropyl methylcellulose (HPMC E15) served as the primary film forming polymer, with chitosan added to provide mucoadhesion. Piperine, a natural bioenhancer, was included to promote transmucosal transport, while glycerin and propylene glycol acted as plasticisers. Citric acid was used to regulate pH and sodium benzoate as a preservative. The films were fabricated by solvent casting in a 100 mL batch, producing 100 units each containing 1 mg of Saroglitazar. The final films were smooth, uniform and 2.0 mm thick with consistent weight. Folding endurance exceeded 300 cycles, confirming good flexibility. Surface pH was maintained at 6.5, supporting mucosal compatibility. Drug content uniformity was close to 90%of the stated dose per unit. The films also demonstrated adequate mucoadhesion and stable moisture content under storage. This formulation provides a promising delivery strategy for bypassing first-pass metabolism while overcoming permeability barriers. The combination of natural bioenhancers and mucoadhesive polymers adds novelty and positions the system as a potential candidate for patent protection.

**Keywords:** Saroglitazar, buccal film, mucoadhesion, bioenhancer, solvent casting.

**FORMULATION AND EVALUATION OF FLOATING ALGINATE BEADS OF METFORMIN HYDROCHLORIDE**

Nilotpal Choudhury* and Bitopan Baishya
Department of Pharmaceutical Chemistry, NETES Institute of Pharmaceutical Science,
NEMCARE Group of Institutions, Mirza, Kamrup, Assam- 781125
choudhuryn51@gmail.com

The objective of this study was to develop and evaluate metformin hydrochloride-loaded microbeads using the ionic gelation technique for controlled drug delivery. Five different formulations (F1–F5) were prepared by varying the concentrations of sodium alginate, a natural

ISBN: 978-81-980623-8-3

polymer, and using calcium chloride as the cross-linking agent. The prepared microbeads were subjected to a series of in vitro evaluation parameters, including particle size analysis, percentage yield, entrapment efficiency, and swelling index. Among all formulations, F3 exhibited the most favorable characteristics, showing the highest percentage yield of 68.51% and an entrapment efficiency of 88.25%, indicating effective drug incorporation and process efficiency. An in vitro drug release study was conducted for the optimized formulation (F3), which demonstrated a sustained release profile, with 79.82% of the drug released over a period of 8 hours. Drug release kinetics were analyzed, and the results indicated that all formulations followed a zero-order kinetic model with Fickian diffusion, suggesting a consistent and controlled release mechanism. Compatibility between the drug and excipients was confirmed using Fourier Transform Infrared Spectroscopy (FTIR), showing no significant interactions. Additionally, Scanning Electron Microscopy (SEM) confirmed the spherical morphology and smooth surface of the microbeads.In conclusion, the formulated microbeads exhibit promising potential as an effective drug delivery system for achieving sustained and controlled release of metformin hydrochloride, enhancing therapeutic efficacy and patient compliance.

**Keywords:** metformin hydrochloride, controlled drug delivery, ionic gelation

## NEEDLELESS INJECTION – A PAINLESS PARENTERAL DELIVERY FOR IMPROVISED PATIENT COMPLIANCE

Sharanya Pallerla, Rajasekhar Poonuru.
Department of Pharmaceutical Sciences, St. Peter's Institute of Pharmaceutical Sciences, Hanumakonda, Telangana, India- 506001.
sharanyapallerla1@gmail.com

When it comes to quick start of action, no drug waste, and avoiding first-pass metabolism, parenteral medication delivery is the most outstanding option. Nevertheless because of the severe pain and suffering it generates, it is least desired in terms of patient comfort. In order to deliver medication through the skin without the use of a traditional needle, needleless injection, also known as needle-free injection, uses a device-generated high-velocity jet of liquid or powder. This technique boosts patient comfort and compliance while minimizing the risk of needlestick injuries, pain, and needle phobia. These devices make medicine delivery safer and more convenient by creating a fluid "needle" that pierces the skin's protective outer layer using processes like spring power, gas pressure, or laser technology. Needleless injections are a chosen option due to their reduced pain and anxiety, increased stability, decreased infections, safety for healthcare providers, and improved patient compliance and adherence. These are versatile enough to offer liquid and powder formulations driven by gas, spring, or piezoelectric methods, as well as depot formulations for extended release. The major setbacks are risks of cross-contamination, under-dosing, and skin damage. Certain needle-free devices use high pressure, which can harm delicate drug molecules, especially when administering complex biological medications like monoclonal antibodies. In order to improve control, newer jet injectors are being developed with configurable parameters to accommodate varying skin thicknesses and desired depths.

**Keywords:** Needless Injections, Painless, Injectors, Suffering, Adherence.

**PC-592**

## SLN BASED DELIVERY OF CYTARABINE FOR THE EFFECTIVE MANAGEMENT OF LEUKEMIA

Rakesh Raja*a and Pooja Mongia Rajbb
a Department of Pharmacy, Meerabai DSEU Maharani Bagh Campus New Delhi 110065
b DIPSAR, Delhi Pharmaceutical Sciences and Research University Delhi 110017

Treatment protocols for leukemia are associated with several side effects. For effective management of this disease chemotherapy is generally used alone as well as in combination of other therapies. In such cases, trained medical personnel with close monitoring of therapeutic responses is essentially required as these protocols are generally employed through parenteral route e.g. infusion or injection. The poor patient compliance for these routes of administration is well known. In such scenario alternative administration of formulations is urgent need to avoid side effects as well as increase patients comfort. Cytarabine (cytosine arabinoside, 1-b-D-arabinofuranosyl cytosine) is an anticancer drug belonging to pyrimidine nucleoside analogue. It is one of the mainstays used in the treatment of acute myeloid leukemia, non-Hodgkin's lymphoma (blast phase) and erythroleukemia. SLN were prepared by ultrasonic emulsification method showed uniform with size range 174 ± 5.3 to 226 ± 10.5 and zeta potential 29.2 ± 6.4 to -44.2 ± 0.8 mV. The optimum formulation showed smooth surface through SEM and after some fast delivery, release rate became slow after 4 h and remained for 144 h. In vivo performance of the formulation showed promising anticancer effect on cell and also on mice as compared to controlled as well as standard therapy.

**Keywords:** anticancer, cytarabine, invitro release, sustained effect and leukemia.

**PC-593**

## TAILORED ANTIMICROBIAL NANOFIBERS: COMPARATIVE STUDY OF SILVER NANOPARTICLE ENCAPSULATION IN NATURAL AND SYNTHETIC POLYMER SYSTEMS

Ankita Dubey(1), Dr. Abhijeet Joshi(2), Dr. Mirza S. Baig(3), Dr. G.N. Darwhekar(4)
(1, 4) Acropolis Institute of Pharmaceutical Education & Research, Indore
(2,3) Biosciences and Biomedical Engineering, IIT, Indore
ankita@acropolis.edu.in

The escalating threat of antimicrobial resistance demands innovative therapeutic approaches beyond conventional antibiotics. This study investigates silver nanoparticle (AgNP) encapsulation within diverse polymeric nanofiber matrices to develop effective antimicrobial materials. Four polymer systems were evaluated: gelatin type A and cellulose (natural polymers), polyvinyl alcohol (PVA), and gelatin-polyvinylpyrrolidone K-90 composite (synthetic/hybrid systems). Silver nanoparticles were synthesized in situ in polymeric solutions and incorporated into polymer solutions for electrospinning fabrication. Resulting nanofibers exhibited diameters ranging 400nm-1µm with uniform AgNP distribution confirmed via scanning electron microscopy and X-ray diffraction analysis. Antimicrobial efficacy was assessed against Gram-positive bacteria like S aureus and MRSA, and Gram-negative E coli and Pseudomonas aeruginosa, as well as on fungi Candida albicans, using disk diffusion. Gelatin-PVP composite nanofibers demonstrated superior performance with the highest zones of inhibition, followed by gelatin type A, PVA, and cellulose systems. Natural polymer matrices facilitated enhanced silver ion release through hydrophilic interactions and protein-based functional groups. The composite gelatin-PVP system exhibited optimal sustained release characteristics, maintaining antimicrobial activity for 72-96 hours. This comparative analysis establishes that polymer matrix selection critically influences antimicrobial efficacy and biocompatibility. Natural polymer-based systems, particularly gelatin type A and PVP K-90 composites, offer superior therapeutic potential for wound care and infection control applications, providing a foundation for rational design of next-generation antimicrobial materials. Cytotoxicity evaluation of silver nanoparticles using L929 fibroblasts confirmed biocompatibility across all systems, with natural polymers showing superior cell viability.

## FORMULATION AND EVALUATION OF COROSOLIC ACID-LOADED NANOEMULGEL FOR TREATMENT OF PSORIASIS AND INFLAMMATORY CONDITIONS

Mokshada Bhavsar, Tanmay Dalvi, Dr.Srinivas Nandayala, Dr.Kuldep Vinchurkar, Dr.Lakshmikant Borse.
Sandip Institute of Pharmaceutical Sciences.

Psoriasis is a chronic, immune-mediated inflammatory skin disorder characterized by keratinocyte hyperproliferation, erythematous plaques, and relapsing symptoms that significantly affect patients' quality of life. Conventional therapies, although effective, are often associated with adverse effects, drug resistance, and poor patient compliance. In this context, herbal bioactives have gained prominence as safer alternatives. Corosolic acid, a pentacyclic triterpenoid with proven anti-inflammatory, antioxidant, and immunomodulatory properties, presents promising

ISBN: 978-81-980623-8-3

potential for psoriasis management. The present study aims at the development of a corosolic acid-loaded nanoemulgel formulation to enhance solubility, stability, and skin penetration of the bioactive. A nanoemulsion of corosolic acid was first prepared using oil, surfactant, and co-surfactant by spontaneous emulsification method, followed by incorporation into a suitable gel base to achieve a nanoemulgel system. This hybrid formulation offers the dual advantage of the enhanced permeation profile of nanoemulsions and the topical applicability and retention of gels. The developed nanoemulgel is expected to improve therapeutic efficacy, ensure sustained release, and minimize systemic side effects. Such a formulation could serve as an effective, patient-friendly, and herbal-based alternative for the topical treatment of psoriasis, aligning with the growing trend towards safe and natural remedies in dermatological care.

**Keywords:** Psoriasis Corosolic acid Nanoemulgel Herbal bioactives Topical drug delivery Anti-inflammatory

## PHARMACEUTICAL DESIGN AND IN-VITRO EVALUATION OF CALOTROPIS GIGANTEA-BASED NANOFORMULATION FOR DERMATOLOGICAL THERAPY

TILOTMA SAHU

The present study focuses on the formulation, characterization, and in-vitro evaluation of a Calotropis gigantea-based topical nanoformulation aimed at improving therapeutic outcomes in dermatological disorders. Fresh latex of Calotropis gigantea was collected from stem incisions and analyzed for phytoconstituents using HPLC. A nanoformulation in the form of hyalurosomes was prepared by the ethanol injection–solvent evaporation method. The prepared system was subjected to comprehensive characterization including particle size, polydispersity index (PDI), zeta potential, entrapment efficiency, viscosity, morphology through transmission electron microscopy (TEM), and in-vitro drug release studies. A conventional Carbopol-based gel was also formulated to serve as a comparative standard. For mechanistic evaluation, Rhodamine-loaded hyalurosomes (CGHNF) were developed and employed for cellular uptake studies. Pharmacological assessments included cell uptake efficiency, cell viability assay, melanin content assay, tyrosinase activity assay, and Fontana-Masson silver staining using the B16F10 cell line. Phytochemical profiling revealed lupeol, β-amyrin, α-calotropeol, β-calotropeol, uscharin, and 20-epi-uscharin as the major bioactive compounds in the latex. The developed nanoformulation displayed an average particle size of 154.90 ± 1.7 nm, a PDI of 0.28, and a zeta potential of –17.00 mV. Entrapment efficiency was found to be 84.56%. Cellular uptake studies demonstrated significantly enhanced internalization (60.60 ± 3.23%) for Rhodamine-CGHNF compared with free dye solution (32.01 ± 4.85%). The cell viability assay indicated superior cytotoxicity of CGHNF (68.71 ± 2.76%) over the Carbopol gel (52.10 ± 9.63%) at 50 µM concentration. Furthermore, assays on melanin synthesis and tyrosinase activity suggested the formulation's potential in regulating skin pigmentation pathways. The study successfully developed a Calotropis gigantea-based nanoformulation with nanoscale size, high entrapment efficiency, and improved cellular penetration. The deformable nature of hyalurosomes, along with sustained drug release, highlights their potential to enhance dermal delivery and reduce dosing frequency. Comparative studies established the superiority of the nanoformulation over the conventional Carbopol gel in terms of cell uptake and therapeutic activity.

**Keywords:** Calotropis gigantea, hyalurosomes, nanoformulation, dermatological therapy, B16F10 cell line, HPLC, cell uptake

## QUALITY BY DESIGN-DRIVEN OPTIMIZATION OF CAFFEIC ACID CUBOSOMES: A BIOAVAILABLE NANOPLATFORM FOR BREAST CANCER TREATMENT

AMOL MANIK PATIL

Breast cancer is among the major contributors in the death of women due to cancer. Polyphenol, especially in the form of caffeic acid (CA), derived from plants, has been demonstrated to have good anticancerous activity, but its clinical applications are inhibited by less water solubility, instability and high rate in clearing out of the systems. Here, this study is intended to develop and optimise CA loaded cubo-somes (CA-CN) with quality by design (QbD) to advance the therapeutic potential associated with breast cancer. To study the impact of glyceryl monooleate (GMO) concentration, Poloxamer 407 concentration and sonication time on the particle size, zeta potential and entrapment efficiency, a three-factor three-level Box- Behnken Design (BBD) was used. The optimized formulation exhibited particle size of 101 nm and zeta potential of -30mV showing good colloidal stability. In the design study it was seen that the increase in Poloxamer 407 concentration and sonication time decreased particle size and entrapment efficiency considerably and that the increase in GMO concentration provided larger particle and moderate drug encapsulation. The successful encapsulation and a transition of CA to an amorphous form favoring its solubility enhancement were proved by FTIR, XRD, and DSC researches. Bioavailability and drug release were enhanced after in vitro and in vivo testing which proved CA-CN to be effective. The pharmacokinetic profile in rabbits revealed that CA-CN was associated with 3.08-fold higher bioavailability than pure CA. Conclusively, the developed cubosomal system significantly improved CA's physicochemical and pharmacokinetic profiles, indicating that it could be used as a nanocarrier for breast cancer treatment. Further research can consider the active targeting approach and scale-up feasibility to shift toward clinical development.

## CHRONOMODULATED DRUG DELIVERY SYSTEM OF VERAPAMIL HYDROCHLORIDE

Sathish reddy Chinnapundra and Rajeshri Dhurke
St.Peter's Institute of Pharmaceutical Sciences, Vidyanagar, Hanamkonda 506001, Telangana State, India.
sathishreddychinnapundra@gmail.com

Aim of the present work was to formulate and evaluate an oral pulsatile delivery system for treatment of arrhythmias which usually occurs in early morning hours. Pulsatile tablets were prepared using different concentrations of polymers (HPMC E15, Carbopol 934P) to achieve time release of verapamil hydrochloride, based on chronopharmaceutical approach. Such delivery systems when administered at bed time, shows burst effect after the lag time there by delivering the drug where it is required most. Pulsatile tablets of verapamil hydrochloride were prepared by compression coating technique. The press coated tablets contains inner rapid release core tablet contains active ingredient (drug) and external coat comprises of polymers such as HPMC E15 and Carbopol 934P. Several pulsatile formulations were prepared and evaluated for various parameters like weight variation, hardness, thickness, content uniformity, swelling index and in-vitro drug release study. Solid state characterization (FTIR studies) indicated that there no chemical interaction between drug and excipients. Swelling index and water uptake studies showed linearrelation between swelling and lag time.In vitro dissolution study was carried out for 8 hours using USP type II dissolution apparatus (paddle) with 0.1N HCl as dissolution medium. Based on the in vitro release data it was evident that the developed formulation F7 coated with 380 mg HPMC and 5mg Carbopol 934P showed lag time 5 hours, and percent drug release was found to be 98% at 6th hour, hence considered to be optimum.

**Keywords:** Chronomodulated, pulsatile, verapamil, lag time

## "DEVELOPMENT AND CHARACTERIZATION OF A VAGINAL SPRAY: A PROMISING APPROACH FOR OVERCOMING ANTIFUNGAL RESISTANCE IN VAGINAL CANDIDIASIS"

Janhvi Shetty, Mahima Salian, Rani Katekar, Isha Kavedia, Jaya Agnihotri, and Tushar Lokhande.
Department of Pharmaceutics, H.K College of Pharmacy, Mumbai, Maharashtra, India, 400102
janhvishetty0812@gmail.com

Vaginal candidiasis, primarily caused by Candida albicans, is one of the most common fungal infections affecting women worldwide. Symptoms such as itching, irritation, and abnormal discharge not only cause physical discomfort but also contribute to emotional distress. Conventional antifungal therapies, particularly triazoles like fluconazole, are increasingly limited by high relapse rates and widespread resistance, with reports indicating resistance in over 90% of clinical isolates. This

ISBN: 978-81-980623-8-3

highlights the urgent need for innovative therapeutic approaches that combine efficacy, safety, and patient convenience. This study presents a novel herbal–synthetic combination vaginal spray, engineered to overcome the limitations of current antifungal treatments and enhance therapeutic outcomes. The system integrates fluconazole, a clinically established antifungal, with thymol, a phytoconstituent from Thymus vulgaris essential oil, to achieve a synergistic dual mechanism of action capable of combating resistant Candida strains. The spray-based platform is designed to improve stability of volatile herbal components, minimize irritation, and avoid dose dumping commonly associated with semisolid formulations, while offering a user-friendly mode of administration that enhances compliance. Formulation development and optimization are guided by a Quality by Design (QbD) framework, ensuring reproducibility, robustness, and patient safety. Comprehensive characterization including pH, viscosity, spray performance, droplet size distribution, drug content uniformity, stability will provide critical insights into formulation performance and therapeutic potential. By integrating the strengths of synthetic and natural antifungals within an advanced spray system, this approach offers a promising, patient centered strategy for the effective management of resistant vaginal candidiasis, with potential to improve therapeutic outcomes and overall quality of life.

## SIRNA AND STEROID-ENRICHED LIPOSOMES AS A DUAL THERAPEUTIC STRATEGY FOR PSORIASIS TREATMENT

Madhulika Pradhan1
School of Pharmacy, Rungta International Skills University, Bhilai, Chhattisgarh, INDIA.
madhulika.pradhan1@gmail.com

Psoriasis is a chronic inflammatory skin disorder characterized by elevated expression of Interleukin-17 (IL-17), a key cytokine driving its pathogenesis. The advent of short interfering RNA (siRNA) has introduced new therapeutic opportunities to suppress the overexpression of such pathogenic genes. Effective siRNA delivery, however, requires suitable carriers that can both protect and release siRNA into target cells. In this study, a liposomal formulation co-loaded with Betamethasone propionate (BMP) and IL-17 siRNA was developed for topical psoriasis therapy. The optimized liposomes exhibited an average particle size of 312±1.92 nm, a zeta potential of –27 mV, and successfully co-encapsulated BMP with complexed siRNA. The formulation demonstrated high cellular uptake without detectable cytotoxicity. In vitro skin permeation studies using a porcine skin model confirmed effective delivery of both BMP and siRNA into the skin. Furthermore, in vivo evaluation in an imiquimod (IMQ)-induced psoriasis mouse model showed that treatment with BMP–IL-17 siRNA liposomes significantly reduced IL-17A cytokine levels (ELISA), correlating with visible improvements in skin redness and scaling. Overall, these findings highlight the potential of the developed liposomal system as a dual-function platform for gene silencing and corticosteroid delivery in the topical management of psoriasis.

Keywords: siRNA, Clobetasol propionate, Liposome, Imiquimod, and Box-Behnken Design.

## RESPIRAVITAL: ADVANCED NANOEMULSION DRUG SYRUP FOR ENHANCED RESPIRATORY AND IMMUNE SUPPORT

Ganesh Muleva, Soham Joshi, Dr. Kuldeep Vinchurkar
Sandip Institute of Pharmaceutical Sciences

RespiraVital is a cutting-edge nanoemulsion-based drug syrup formulated to optimize the bioavailability of Alstonia scholaris and Andrographis paniculata extracts, targeting robust respiratory relief and immune system enhancement. The formulation incorporates 200 mg/100 mL of standardized Alstonia scholaris extract, valued for its bronchodilatory, anti-inflammatory, and antimicrobial properties, alongside 150 mg/100 mL of Andrographis paniculata extract (standardized to 10% andrographolide), recognized for its potent immunomodulatory and antiviral effects. The nanoemulsion system, comprising medium chain triglycerides (MCT oil) as the oil phase, polysorbate 80 as the surfactant, and polyethylene glycol 400 as the co-surfactant, ensures superior solubility, stability, and absorption of these bioactive compounds. Complementary ingredients, including glycerol for viscosity and humectant properties, stevia extract as a natural sweetener, potassium sorbate as a preservative, and citric acid for pH adjustment (targeting 4.5–5.5), enhance palatability, stability, and shelf-life. This synergistic, patient-friendly drug formulation is designed to support respiratory health and bolster immune function, offering a novel approach to natural therapeutic intervention with improved pharmacokinetic profiles and enhanced patient compliance.

## INNOVATIVE WOUND DRESSING FOR ANTI-COAGULATED PATIENTS

Nupur Amit Mali*, Dr. Lakshmikant Borse, Guide: Dr. Kuldeep Vinchurkar.
*Sandip Institute of Pharmaceutical Sciences, Mahiravani, Nashik.

Bleeding leads to a critical risk in patients on anticoagulant therapy specifically patients of heart diseases, which complicate wound management and causes problem in healing. Normal dressings fail in providing rapid hemostasis and real-time bleeding detection, especially in high-risk patients. The project focuses on the development of a novel smart wound dressing that integrates colorimetric bleeding detection such as ph. detecting solution of blood, with a herbal-based hemostatic matrix(CHITOSAN, MORINGA OLIFERA), designed specifically for anticoagulated individuals such as cardiac and diabetic patients. The dressing comprises an outer colorimetric layer that visually detects the presence of fresh bleeding through a pH-sensitive dye, providing an early detection. The inner layer incorporates Moringa oleifera extract and Chitosan, both known for their potent, coagulant, antimicrobial, and wound-healing properties. Moringa, a plant-based agent which is rich in tannins, flavonoids, and bioactive polyphenols, enhances clot formation while minimizing inflammation and infection. Chitosan, a natural polysaccharide derived from crustacean shells, contributes by accelerating clotting through platelet adhesion and aggregation, while forming a protective gel barrier to prevent microbial attack.The main idea is to get rapid clotting, biocompatibility, and structural integrity. The product gives best results promising results in clotting time reduction, improved wound closure, and controlled bleeding when compared with other dressings.This smart dressing not only addresses the urgent need for targeted bleeding control in anticoagulated patients, but also helps with the principles of sustainable, herbal-based wound care technologies. It can be used in emergency care, post-operative management, and home care settings. This product idea is patented and has been published. The innovation offers a cost-effective, accessible, and patient-friendly solution to improve clinical outcomes for heart patients specifically.

**Keywords:** wound dressing, ph. blood detection, Moringa oleifera, Chitosan, Hemostatic matrix, Anticoagulated patients, Rapid hemostasis and Herbal wound care.

## TRANSDERMAL NANOPARTICLE DELIVERY OF LEVETIRACETAM: A PHARMACY-LED INNOVATION FOR SAFETY EPILEPSY CARE IN PREGNANCY

Janipalli Samya and Ramakrishna Gummadi
Department of Pharmacy Practice, School of Pharmacy, Aditya University, Surampalem, Kakinada-533437
samyajanipalli2873@gmail.com

Epilepsy during pregnancy increases maternal morbidity, preterm birth, and fetal risks due to uncontrolled seizures or fluctuating drug levels. Levetiracetam (LEV) is widely prescribed, but oral and parenteral routes show variable plasma concentrations and poor adherence during acute episodes. Nanoparticle-based transdermal delivery offers sustained release, improved compliance, and reduced fetal exposure, representing the first pharmacist-driven nanomedicine innovation in India with direct translational relevance. To develop and evaluate LEV-loaded solid lipid nanoparticle (SLN) transdermal patches as a safe, sustained, and patient-friendly therapy for pregnancy epilepsy. LEV-SLNs were prepared via solvent evaporation with stearyl amine and Tween-80, surface-modified

ISBN: 978-81-980623-8-3

with 3-carboxy phenyl boronic acid, and incorporated into hydrogel patches. Characterization included particle size, zeta potential, drug entrapment, in vitro release, ex vivo skin permeation, stability, and safety (HET-CAM, MTT). Experiments were performed in triplicate; statistical significance was assessed using ANOVA ($p < 0.005$). Optimized SLNs had 182 ± 12 nm size, +28 mV zeta potential, and 84.6% entrapment. Patches showed uniform thickness, high drug content (98.3%) and sustained biphasic release (78% at 24 h). Skin permeation flux exceeded that of plain LEV hydrogel (42.5 vs 25.1 µg/cm2/h, $p < 0.05$). Stability remained above 90% at 30 days, and no cytotoxicity or irritation was observed. LEV-SLN transdermal patches demonstrated controlled release, enhanced skin permeability, and favorable safety, providing a robust translational platform for pharmacist-led maternal epilepsy care in India. By potentially improving adherence and reducing fetal exposure, this approach bridges lab research and future clinical application, emphasizing its novelty and practical relevance.

## DEVELOPMENT, OPTIMIZATION AND CHARACTERIZATION OF NIOSOMES BASED DRUG DELIVERY SYSTEMS FOR SURGICAL WOUNDS

Pooja M. Raj, Anshul, B. Bahera, Varsha Vashisht
Delhi Pharmaceutical Sciences and Research University, Pushp Vihar, New Delhi-110017

Niosomes increase stratum corneum hydration and changes its properties by reducing trans epidermal water loss. This research focuses on the development, optimization and characterization of optimized niosomes containing hesperidin, with the aim of enhancing wound management. The study involves the design and preparation of niosomes using appropriate surfactants and cholesterol to encapsulate hesperidin efficiently. Characterization techniques such as size analysis, morphology assessment, encapsulation efficiency determination, melting point studies were carried out for the optimized formulation. The in vitro and in vivo evaluation of the optimized niosomes of hesperidin for wound healing were conducted in rat models. The optimized hesperidin niosomes had a particle size of 232 nm with a zeta potential of -16.32mV. The entrapment efficiency was found to be 90%. The peak at 3312.14 cm-1 corresponds to the stretching vibration of -OH groups. Another peak at 1639.17 cm-1 represents stretching vibrations of carbonyl groups. The DSC peaks are obtained 64.244°C and 92.614°C which indicates a phase transition or melting event. The cumulative (%) release in phosphate buffer saline (pH=7.4) of optimized hesperidin loaded niosomes showed 96.88% of the drug within 24 hours. The wound closure (%) for the control group after 7 and14 days were found to be 20 ± 0.88 cm and 72±0.69 cm for control group respectively, 52±1.18 cm and 98±1.2 cm for hesperidin loaded niosomal gel respectively. Hesperidin loaded niosomal gel produced maximum contraction of the wound, formation of epidermal layer and remodeling. The epidermal layer was totally formed, due to healing property of hesperidin.

**Keywords:** Hesperidin, niosomes, remodeling, wound healing, zeta potential,

## FORMULATION AND EVALUATION OF A HERBAL SUNSCREEN MIST FOR BROAD-SPECTRUM UV PROTECTION

Pranjal Patil*, [Prof.Karuna Kadlag],[Dr.Kuldeep Vinchurkar] [Dr.Laxmikant Borse].
Sandip Institute of Pharmaceutical Sciences,Nashik.
pranjalp372@gmail.com

This project focuses on the formulation and evaluation of a herbal sunscreen designed to provide broad-spectrum protection against both UVA and UVB rays. The product is prepared using natural ingredients such as aloe vera, carrot seed oil, and green tea, which are widely recognized for their antioxidant, soothing, and photoprotective properties. Carrot seed oil and wheat germ oil together expect to show synergistic effects.Unlike conventional chemical sunscreens, this herbal formulation offers safe and eco-friendly skin protection without parabens, synthetic additives, or artificial fragrances. It is lightweight, non-greasy, and ensures quick absorption, making it more comfortable for daily use. Along with sun protection, the herbal actives nourish the skin, help prevent oxidative damage, reduce premature aging, and maintain skin hydration. Being suitable even for sensitive skin, this herbal sunscreen aligns with the increasing demand for sustainable and natural skincare products.Overall, the formulation presents a safe, effective,and consumer-friendly alternative to chemical-based sunscreens.

## FORMULATION AND EVALUATION OF MATRIX-TYPE TRANSDERMAL PATCH CONTAINING ISTRDEFYLLINE

Manjunatha T O and Barnabas Wilson
Department of Pharmaceutics, College of Pharmaceutical Sciences, Dayananda Sagar University, Harohalli, Bengaluru – 562112, Karnataka, India
maligemanju@gmail.com

Effective management of Parkinson's disease necessitates maintaining consistent plasma drug concentrations to mitigate "on-off" phenomena and enhance therapeutic outcomes. The present study focused on the development, optimization, and in vitro evaluation of matrix-type transdermal therapeutic system for the sustained delivery of istradefylline. Istradefylline, a selective adenosine $A_2A$ receptor antagonist, is used for treating Parkinson's disease. Transdermal patches were fabricated using solvent casting method incorporating polymers chitosan and CTC with dibutyl phthalate as plasticizer. The prepared transdermal patch was evaluated for thickness, weight variation, folding endurance, moisture content, and drug content uniformity and the results were 0.28 ± 0.02 mm, <5%, >200, 2.1 ± 0.3%, 98.5 ± 2.1% respectively In vitro drug release and permeation studies were conducted over 36 hours using Franz diffusion cells equipped with a synthetic cellulose acetate membrane. The formulation demonstrated a sustained release profile (92.1± 1.8%), which adhered to the Higuchi kinetic model ($R^2$ = 0.992), indicating a diffusion-controlled release mechanism. Permeation studies revealed a steady state flux of 12.5 ± 0.8 µg/cm²/h. These findings suggest that the developed transdermal patch offers a promising non-oral strategy for the continuous administration of istradefylline, with the potential to significantly improve patient compliance, minimize dosing frequency, and stabilize pharmacokinetics in treating Parkinson's disease.

**Keywords:** Parkinson's disease, transdermal patch, istradefylline, sustained release, solvent casting, Franz diffusion cell.

## QUERCETIN AND RUTIN-LOADED NANOCARRIERS: A SYNERGISTIC STRATEGY FOR ANTIOXIDANT AND ANTI-AGING APPLICATIONS

Kavya M and Gayathri R
Department of Pharmaceutics, KMCH College of Pharmacy, Coimbatore, affiliated to The Tamil Nadu Dr. M.G.R. Medical University, Chennai, Tamil Nadu, India-641 048
official.kavya22@gmail.com

Background: Quercetin and rutin are flavonoids with strong antioxidant, anti-inflammatory, and anti-aging properties. However, their therapeutic potential is limited by poor aqueous solubility, instability, and inadequate skin penetration. Nanocarrier-based delivery systems can enhance dermal bioavailability and therapeutic efficacy. Objective: To develop and evaluate nanocarrier formulations of quercetin and rutin for improved stability, antioxidant activity, and anti-aging efficacy in dermal applications. Methods: Quercetin- and rutin-loaded liposomal systems were prepared using thin-film hydration and optimized for particle size, polydispersity index, zeta potential, and entrapment efficiency. Characterization was performed via dynamic light scattering, transmission electron microscopy, FTIR, and DSC. Antioxidant activity was assessed using DPPH and ABTS radical scavenging assays. Ex vivo skin permeation was studied using Franz diffusion cells, while in-vitro anti-aging potential was evaluated in fibroblast cultures through collagen synthesis and MMP inhibition assays. Results: The optimized formulations exhibited nanoscale particle size (<200 nm), high entrapment efficiency (>85%), and sustained release profiles. Encapsulated flavonoids demonstrated significantly enhanced antioxidant activity compared to free quercetin and rutin ($p < 0.05$). Skin permeation and retention studies confirmed improved dermal delivery.

ISBN: 978-81-980623-8-3

Fibroblast assays revealed increased collagen synthesis and reduced matrix metalloproteinase activity, indicating strong anti-aging efficacy. Conclusion: Nanocarrier-mediated delivery of quercetin and rutin enhances their stability, dermal penetration, and biological activity, offering a synergistic and effective approach for combating oxidative stress and delaying skin aging. These findings support the potential of dual-flavonoid nanocarriers as promising candidates for advanced cosmeceutical and therapeutic applications.

**FORMULATION, OPTIMIZATION AND CHARACTERIZATION OF DUAL DRUG LOADED POLYELECTROLYTE NANOPARTICLES FOR THE TREATMENT OF CANCER**

Suman Ramteke, Rahul Singh and Akshat Sahu
School of Pharmaceutical Sciences, Rajiv Gandhi Proudyogiki Vishwavidyalaya, Bhopal (M.P) 462033
Suman@rgpv.ac.in

In the current research, dual drug-loaded polyelectrolyte nanoparticles (PENPs) were prepared using hyaluronic acid (HA) and chitosan (CS) polymers. Objective behind the research was to formulate and optimize dual drug-loaded system with significant drug entrapment and release. The PENPs was formulated spontaneously when oppositely charged polyelectrolytes interact via electrostatic attraction. Optimization was performed on design of expert (DoE), it was found that PENPs-2 with the smallest particle size (144.6 nm) and positive zeta potential (20.2) observed at a mass ratio of HA to CS was 4.68:4 and rotation speed of 3000. An equimolar amount of 5-fluorouracil (5-FU) and quercetin (QT) was loaded. It was found that the particle size 451.3 nm, the zeta potential was 29.7 mV, and the entrapment efficiency 69.83% for 5-FU and 98.73% for QT, with corresponding drug loading percentages of 21.63% and 15.27%. FTIR analysis validated the compatibility of drugs with the polymer matrix, ensuring the integrity of PENPs. Cumulative release studies conducted at pH 5.0 and 7.4 highlighted the superior release profile in acidic conditions. Interestingly, QT exhibited more pronounced release than 5-FU in both acidic and neutral conditions. Stability studies revealed that blank PENP experienced a notable increase in particle size (from 144.6 nm to 245.1 nm). However, the drug-loaded PENPs showed only a slight increase in particle size (from 451.3 nm to 463.5 nm) and zeta potential (from 29.7 mV to 29.1 mV), indicating good stability. Thus, it can be concluded that this study is beneficial for the formulation of dual drug-loaded PENPs.

**Keywords:** hyaluronic acid, chitosan, polyelectrolyte, 5-fluorouracil, quercetin.

**NIOSOMAL BASED TRANSDERMAL GEL FOR ATTENTION-DEFICIT HYPERACTIVITY DISORDER**

sai shashank Mamidi and Rajashri Dhurke
St. Peter's Institute of Pharmaceutical Sciences, Vidyanagar Hanamkonda, 506001, Telangana State, India,
saiseesfuture435@gmail.com

Methylphenidate is a drug of choice used in the treatment of attention-deficit hyperactivity disorder in children and for narcolepsy. The aim of present study was to develop niosomal based transdermal gels for controlled delivery of methylphenidate for prolonged period of time. Methylphenidate has very low bioavailability due to extensive first pass metabolism. Bioavailability of methylphenidate can be improved by transdermal delivery systems as drug directly reaches systemic circulation avoiding first pass metabolism. Non-ionic surfactant vesicles (niosomes) with different ratios (1:1-3:1) were prepared by thin-film hydration method using rotary flash evaporator and then incorporated in to 3% w/v Carbopol 934 gel base. Niosomal based gel had good consistency, spreadability and pH was around 6.5. FTIR and DSC studies revealed that there were no physical and chemical interactions between drug and excipients. Niosomes were analyzed for morphological aspects like vesicle size, vesicle shape, drug content, entrapment efficiency and in vitro diffusion studies. Vesicles were spherical in shape having uniform size in range of 1-3µm. Formulation (F1) containing 1:1 ratio of mole/mole span 60 and cholesterol showed highest entrapment efficiency of 98.6% and drug content was found to be within the limits. In vitro diffusion studies were conducted using Franz diffusion cell with 7.4 pH phosphate buffer as diffusion media. The formulation F1 showed greater drug release of 98.73% in 9 h compared to other formulations which released less than 80 % of drug in 9 h. Flux obtained for F1 formulation was higher (0.012±0.002µg/cm2/hr) than those obtained for formulation F2- F6.

**MECHANOCHEMICAL SYNTHESIS OF MEDICINALLY IMPORTANT HETEROCYCLIC COMPOUNDS USING GREEN CATALYST**

Vijay R. Chavan, Prashant S. Kharkar*
Department of Pharmaceutical Sciences and Technology, Institute of Chemical Technology, Nathalal Parekh Marg, Matunga, Mumbai-400019, India
ps.kharkar@ictmumbai.edu.in

In this present study, multiple kind of quinoxaline derivatives were synthesized by employing a solvent-free mechanochemical approach. Quinoxaline derivatives are a significant family of nitrogen-containing heterocyclic compounds that have numerous biological and pharmacological applications. They show antitubercular, anticancer, antibacterial, antiviral, antidiabetic, antifungal, and anti-inflammatory properties. Mechanochemistry, common approach for organic synthesis, which reduces the environmental waste and achieves sustainable development goals in pharmaceuticals and agrochemicals. The reaction had been carried out by mechanically grinding of substituted 1,2-diamines with substituted 1,2-diketones in a mortar and pestle, using green catalysts and excluding the use of standard solvents. The environment friendly process resulted in reduction of reaction time, higher yields and also include different benefits of mechanochemistry like operational simplicity, less environmental impact, and enhanced atom economy. The synthesized compounds were purified and analyzed using FT-IR, 1H NMR, 13C NMR, and Mass spectrometry, confirming the production of the intended heterocyclic structures.

**Keywords:** Quinoxaline derivatives, mechanochemistry, green chemistry, sustainable synthesis, green catalyst.

**DEVELOPMENT AND EVALUATION OF A CARBOPOL-BASED ETHOSOMAL GEL OF PONGAMIA PINNATA EXTRACT FOR ENHANCED TOPICAL DELIVERY**

Balla Sri KrishnaVeni, Gummadi Rama Krishna
Department of Pharmaceutics, Aditya University, Surampalem, Andhra Pradesh, India - 533437.
krishna11veni9@gmail.com

This study aimed to develop and evaluate a Carbopol-based ethosomal gel of Pongamia pinnata for enhanced topical delivery. Pongamia pinnata a medicinal plant known for its anti-inflammatory, antimicrobial, and antioxidant properties, but its therapeutic efficacy in conventional topical formulation is restricted due to skin penetration and limited stability. To overcome limitation, Ethosomes – Flexible nanovesicles comprising phospholipids, ethanol, cholesterol, and propylene glycol were prepared by a modified cold technique. The plant extract and excipients were first dissolved in ethanol, followed by gradual incorporation of the aqueous phase under continuous stirring to form stable vesicles. The ethosomal suspension was subsequently incorporated into Carbopol 940 gel base, neutralized with triethanolamine and stabilized with suitable preservative to yield the final formulation. The ethosomal gel was evaluated for physical appearance, PH, viscosity, drug content, entrapment, spread ability, stability, efficiency and drug release profile. The formulation exhibited a uniform, lump free texture with a physiologically acceptable PH [5.5-6.5] and optimal viscosity for dermal use. Drug content and entrapment efficiency were within acceptable limits, confirming consistent drug incorporation into ethosomal vesicles. Spreadability testing demonstrated smooth and uniform application, while stability studies confirmed good retention of physiochemical characteristics overtime. Invitro release and Invivo permeation studies further revealed enhanced sustained release of extract compared with conventional gel. The Carbopol based ethosomal gel proved to be promising nanocarrier system capable of improving skin penetration and prolonging

ISBN: 978-81-980623-8-3

therapeutic benefits of Pongamia pinnata, supporting its potential using dermatological application.

**Keywords:** Ethosomal gel, Pongamia pinnata extract, Topical delivery, Carbopol 940, Entrapment efficiency.

**DEVELOPMENT OF FLAVONOID ENCAPSULATED PH RESPONSIVE GLYCOSYLATED NANOLIPOSOMES FOR PRECISE THERAPEUTIC APPLICATION IN HEPATOCELLULAR CARCINOMA**

Manjunatha M V
M pharm (Pharmacology), NITTE College of Pharmaceutical Sciences, Bengaluru-64

Hepatocellular carcinoma (HCC), the third leading cause of cancer-related mortality, represents a major global health burden. Conventional treatments—including targeted agents, chemotherapy, and radiotherapy—are frequently limited by systemic toxicities such as alopecia, bone demineralization, emesis, and anaemia, highlighting the need for alternative therapeutics with improved efficacy and safety. Flavonoids, a diverse class of natural polyphenolic compounds, exhibit potent anticancer, antioxidant, and hepatoprotective properties; however, their clinical utility is hindered by poor solubility, low bioavailability, rapid degradation, and difficulties in tumour-specific delivery, particularly within the heterogeneous microenvironment of HCC. To address these limitations, a pH-responsive glycosylated nano-liposomal system was developed for apigenin, a promising but poorly bioavailable flavonoid. This formulation was designed to enhance intracellular uptake in hepatocellular carcinoma cells via precise, pH-sensitive release, thereby optimizing therapeutic activity. Physicochemical characterization confirmed nanoscale particles (~150 nm) with smooth morphology and stable surface properties. The delivery system demonstrated controlled, pH-dependent drug release under in vitro and in vivo conditions, suggesting sustained availability at the tumour site. Anticancer efficacy will be assessed in a diethyl nitrosamine (DENA)-induced HCC animal model. Collectively, these findings underscore the potential of apigenin-loaded pH-responsive glycosylated nanoliposomes as an effective, targeted strategy for HCC management.

**Keywords:** Encapsulated flavonoid Hepatocellular Carcinoma

**OPTIMIZING VENLAFAXINE DELIVERY: A TRANSDERMAL PATCH WITH ENHANCED UNIFORMITY AND PERMEATION**

Kavya Naga Praveena Jakka and Ramakrishna Gummadi
Department of Pharmaceutical Sciences, School of Pharmacy, Aditya University, Surampalem, Kakinada -533437
kavyapraveena2004@gmail.com

A novel kind of transdermal patch for the gradual delivery of the widely used anti-depressant venlafaxine is shown by this invention. The half-life of venlafaxine is normally about five hours, but this patch attempts to distribute the medication gradually and steadily over the course of 24-hour period, allowing patients to continue their treatment without having to take extra doses. Venlafaxine is embedded in a unique ethyl cellulose membrane in the patch, which regulates the drug's release rate. To facilitate drug absorption through the skin, a permeation enhancer such as oleic acid is included in the formulation. This method minimizes the possibility of adverse effects by skipping the digestive system and allowing the medication to enter the bloodstream straight through the skin. The patch is also formulated with a silicone adhesive layer to ensure strong adherence to the skin, along with a protective backing layer to maintain its integrity and effectiveness. Patients may experience better compliance, more stable drug levels, and fewer gastrointestinal side effects with this transdermal system compared to traditional oral pills. The patch may be a good candidate for patent protection due to its creative formulation and design, which offer a promising new method of venlafaxine delivery.

**Keywords:** Transdermal patch, Venlafaxine, Drug delivery.

**FORMULATION AND EVALUATION OF NANOSPONGES IMPREGNATED BANDAGE FOR DIABETIC WOUND HEALING**

Vanitha M, Rakshith K, Meghana G S
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, Karnataka, India -570015.
vanitha29murugan@gmail.com

Introduction: Delayed wound healing is a common complication in diabetes mellitus due to hyperglycaemia, impaired circulation, and infection risk. Even small injuries can become severe. Metronidazole is effective against anaerobic bacteria but shows poor site retention and rapid clearance. To overcome these issues, Metronidazole-loaded β-cyclodextrin nanosponges were developed and incorporated into bandages for diabetic wound care. Methodology: Nanosponges were synthesized by the hot melt method using dimethyl carbonate as a crosslinker. Formulation optimization was performed using Box–Behnken Design under Response Surface Methodology. Characterization was carried out using FT-IR, DSC, XRPD, and NMR. The nanosponges were then impregnated into sterile bandages by the solvent casting method. Discussion and Results: The optimized nanosponges exhibited a mean particle size of 390.3 nm, entrapment efficiency of 83.4%, and zeta potential of –22.0 mV. The prepared bandages showed a drug content of 82.3%, moisture retention of 79.6%, and tensile strength of 3.71 MPa, indicating mechanical suitability for wound application. Antibacterial studies confirmed significant inhibition against Staphylococcus aureus and Escherichia coli. In vitro release studies demonstrated sustained drug release of 89.9% over 48 hours, following a diffusion-controlled pattern. These findings highlight the multifunctional nature of nanosponge-impregnated bandages in wound healing. Conclusion: The nanosponge-loaded bandages present a multifunctional dressing system with prolonged release, antimicrobial activity, and good mechanical strength, making them a promising approach for diabetic wound management.

**TRIPLE COMPONENT BIO-BANDAGES FOR MANAGEMENT OF CHRONIC WOUNDS**

Divya Sahu*, Manju Rawat Singh, Deependra Singh
University Institute of Pharmacy, Pt. Ravishankar Shukla University, Raipur Chhattisgarh 492010

Chronic wounds are major healthcare challenges that affect a significant number of people, often characterized by persistent inflammation, recurrent infection, and impaired tissue regeneration, leading to prolonged healing times and substantial morbidity. Recent wound care strategies often plunge short in addressing the multifaceted pathologies inherent to these complex lesions. This abstract presents the characterization and potential impact of triple-component bio-bandages as an advanced therapeutic approach for the comprehensive management of chronic wounds. These innovative bio-bandages are designed to synergistically integrate three critical functional components: a biologically active matrix, providing a scaffold for cell adhesion and proliferation; integrated antimicrobial protection, to combat persistent bacterial colonization; and responsive drug delivery molecules, enabling continuous monitoring of key wound parameters (e.g., pH, temperature). This approach promises to Characterization assessing mechanical properties (e.g., tensile strength), chemical structure (FTIR), surface morphology (SEM), water vapor transmission rates, in vitro antibacterial activity, and in vivo wound healing efficacy. By combining these elements, triple-component bio-bandages aim to actively modulate the wound microenvironment, accelerate re-epithelialization, mitigate infection, and reduce inflammation, thereby overcoming the critical barriers to chronic wound closure.

**DEVELOPMENT AND EVALUATION OF A BIOCOMPATIBLE SPIRULINA–CHITOSAN HYDROGEL LOADED WITH GREEN-SYNTHESIZED SILVER NANOPARTICLES FOR ANTIMICROBIAL WOUND DRESSING APPLICATIONS**

J.V. Suresh, Poojitha Purimetla, Sreedevi Pappaka
Pharmacognosy Division, Jagan's Institute of Pharmaceutical Sciences, Nellore, Andhra Pradesh, India.
Principal.jvsjips@gmail.com

ISBN: 978-81-980623-8-3

The present study focuses on developing a new wound dressing material by incorporating green-synthesized silver nanoparticles (AgNPs) into a Spirulina–chitosan hydrogel matrix. Spirulina extract was used as a natural reducing and stabilizing agent for synthesizing AgNPs, offering an eco-friendly method with enhanced biocompatibility. The nanoparticles were successfully integrated into a chitosan-based hydrogel, which was further strengthened with Spirulina-derived bioactive compounds to enhance structural and functional qualities. Extensive physicochemical tests confirmed the even distribution of AgNPs within the hydrogel and showed good swelling capacity, porosity, and mechanical stability suitable for wound healing. In vitro antimicrobial tests against Gram-positive and Gram-negative bacteria demonstrated significant broad-spectrum activity, while cytocompatibility assessments indicated minimal toxicity to normal cells. The combination of AgNPs, Spirulina biomolecules, and chitosan gave the hydrogel excellent antimicrobial action and wound-friendly biocompatibility, underscoring its potential as a cost-effective, sustainable, and innovative wound dressing.

**Keywords:** Spirulina, Chitosan hydrogel, Green synthesis, Silver nanoparticles, antimicrobial activity, Biocompatibility, Wound dressing

**NOVEL BIORELEVANT EVALUATION STRATEGIES FOR TRANSMUCOSAL ORODISPERSIBLE FILMS IN NEUROPSYCHIATRIC THERAPY**

Kalyana Sundaram Loganathan, Preeti Karwa, Ayesha Syed, Soundara Kalidass M
Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bangalore – 560027.
karsy.in@gmail.com

The therapeutic management of neuropsychiatric disorders often requires rapid-onset formulations that overcome limitations posed by dysphagia, cognitive impairment, poor solubility, and extensive first-pass metabolism associated with conventional oral dosage forms. Orodispersible films (ODFs) offer a promising transmucosal platform, yet standardized in-vitro evaluation methodologies remain underdeveloped. This study aimed to formulate and optimize a mucoadhesive ODF of a poorly water-soluble neuroactive agent and compare conventional versus modified biorelevant in-vitro assessment approaches. Films were prepared via solvent casting, optimized using Box–Behnken statistical design, and characterized for physicochemical attributes including drug content uniformity, mechanical strength, pH, and moisture behavior. Disintegration was evaluated through a modified slide-frame and ball method simulating lingual force, while dissolution testing employed simulated saliva using USP basket (Apparatus I), paddle–glass disk (PGD), and punch-and-filter (PAF) modifications. Optimized films exhibited consistent drug distribution (CV < 2%), rapid disintegration (<14 s), and tensile strength >5 MPa confirming both patient acceptability and manufacturability. The novel PAF method demonstrated superiority by achieving >90% drug release within 10 minutes. The PGD model yielded ~85% release at 15 minutes, whereas the basket apparatus lagged significantly. Ex-vivo permeation studies on porcine buccal mucosa validated efficient transmucosal transport. Short-term stability under ICH conditions showed no significant variations in performance. These findings highlight the benefits of adopting physiologically relevant dissolution and disintegration models for ODF evaluation, establishing improved quality control tools and translational potential for patient-centric, rapid-action transmucosal therapies in neuropsychiatric care.

**Keywords:** Orodispersible films, Transmucosal delivery, Biorelevant dissolution, Neuropsychiatric therapy, Modified USP apparatus

**PC-617**

**ECO-FRIENDLY TABLET STRIPS: A SUSTAINABLE ALTERNATIVE TO PLASTIC PHARMACEUTICAL PACKAGING**

CHIKKULA PAVANKUMAR*, Farha Farheen , Praveen Devanandan
Department of Pharmacy Practice, St. Peter's Institute of Pharmaceutical Sciences, Hanamkonda, Telangana, India, 506370.
chikkulapavankumar@gmail.com

This study introduces biodegradable tablet strips as a sustainable alternative to plastic pharmaceutical packaging. The aim was to reduce environmental and health risks from plastic waste while maintaining pharmaceutical usability. Strips were developed using renewable natural fibers such as cotton rag, hemp, jute, flax, and mulberry, bonded with gum arabic. To enhance durability, a dual coating of carnauba–beeswax (70:30) was applied, improving mechanical strength and water resistance. The manufacturing process involved fiber cleaning, blending, lamination, sheet casting, and surface waxing. The strips were evaluated for tensile strength, folding endurance, biodegradability, water resistance, and compatibility with pharmaceutical printing inks. Findings showed that the strips offered sufficient strength, flexibility, and printability. They underwent complete biodegradation within 6–8 weeks under composting conditions, unlike plastic strips which persist for decades. The system was cost-effective and adaptable for eco-labeling and green branding. Despite these advantages, limitations such as moderate oxygen and moisture barrier properties, scalability issues, and lack of pharmacopeial compliance remain hurdles for large-scale adoption. Nonetheless, the eco-strips demonstrate strong potential as an environmentally friendly alternative, contributing to sustainable healthcare practices and aligning with UN Sustainable Development Goals 12 and 13. Future improvements through nanocellulose reinforcement and natural polymer blends could further enhance performance and establish industry benchmarks.

**Keywords:** Eco-friendly packaging, biodegradable tablet strips, pharmaceutical packaging, natural fibers, sustainability.

**PC-618**

**FORMULATION AND EVALUATION OF CONTROLLED RELEASE MUCOADHESIVE BUCCAL PATCHES OF ROSUVASTATIN TO ENHANCE THE BIOAVAILABILITY BY FORMING A CYCLODEXTRIN COMPLEX**

Aryan Patiri, Bhargab Jyoti Sahariah and Sanduwinaki Siangshai
Department of Pharmaceutics, NETES Institute of Pharmaceutical Science, Mirza, Assam, India – 781125.
aryanrock9862@gmail.com

This study explores the effectiveness of cyclodextrin complexation with rosuvastatin, a statin inhibitor, and assesses its performance through in-vitro drug release and ex-vivo permeation studies. The results confirm the formation of inclusion complexes between cyclodextrin and rosuvastatin, showing that patches formulated with the drug–β-cyclodextrin binary system improve drug permeation compared to patches without an enhancer. Mucoadhesive patches act as controlled drug delivery systems by adhering to mucosal surfaces and gradually releasing the drug. Rosuvastatin, commonly prescribed for familial hyperlipidemia, dyslipidemia, hypertriglyceridemia, atherosclerosis, osteoporosis, benign prostatic hyperplasia, and Alzheimer's disease, benefits from such systems. β-cyclodextrin, a cyclic oligosaccharide, enhances drug solubility, bioavailability, and stability through complexation. The design of mucoadhesive buccal patches of rosuvastatin requires a multidisciplinary approach that integrates formulation, characterization, and evaluation processes.

**Keywords:** Cyclodextrin, Rosuvastatin, Mucoadhesive patches, Controlled Drug Delivery.

**FORMULATION AND IN-VITRO EVALUATION OF DOMPERIDONE LOADED NANOSTRUCTURED LIPID CARRIERS BY QBD**

Lingampally Sai Srija *, Chekkilla Bhargavi, Nalla Divya Sri
Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Tarnaka, Hyderabad, Telangana, India, 500017
saisrijalingampally@gamil.com

Domperidone is a prokinetic and antiemetic drug that belongs to the dopamine antagonist class. In this study, nanostructured lipid carriers (NLCs) were developed using the high-pressure homogenization method to improve domperidone delivery. Stearic acid and oleic acid were used as solid and liquid lipids, respectively. The prepared NLCs were characterized using Fourier Transform Infrared Spectroscopy (FTIR), and encapsulation efficiency ranged between 64% and 86%. In-vitro release studies showed sustained drug release for up to 12 hours, with higher release observed as the solid-to-liquid lipid ratio increased. Among the nine formulations, F9 demonstrated the highest drug release. Visualization studies confirmed the spherical shape and smooth surface of the NLCs. A $3^2$ factorial design using Design Expert 13 software evaluated variables such as zeta potential, particle size, and drug release. Results indicated that increasing stabilizer concentration and sonication cycles decreased zeta potential (-14.0 mV) and particle size (243 nm) while enhancing drug release (96.33 ± 0.02%). These findings suggest

ISBN: 978-81-980623-8-3

that domperidone-loaded NLCs could provide controlled and sustained release, potentially reducing dosing frequency and improving patient compliance.

**Keywords:** FTIR, Domperidone, Nanostructured lipid carriers, Oleic acid, Stearic acid.

**ORAL SUSPENSION OF DIPHENHYDRAMINE AND ITS ANTI-ALLERGIC ACTIVITY IN GUINEA PIGS**

Tini Nirmalkar#, Dr. Parag Jain*
#Rungta College Of Pharmaceutical Sciences and Research , Bhilai , Chhattisgarh
*Department Of Pharmacy, Rungta International Skills University , Kohka - Kurud Road
tininirmalkar@gmail.com

To formulate an oral suspension of diphenhydramine hydrochloride and evaluate its anti-allergic activity using histamine-induced bronchoconstriction in guinea pigs. Diphenhydramine suspension was prepared using sodium carboxymethyl cellulose as a suspending agent, with glycerine and sorbitol for palatability. The formulation was tested for sedimentation rate, redispersibility, and pH. Six guinea pigs were divided into control and test groups. Animals were exposed to 0.2% histamine aerosol, and the onset of respiratory distress was recorded. The test group received diphenhydramine suspension 30 minutes prior to exposure. The diphenhydramine suspension was stable and palatable. Treated animals showed delayed onset of bronchoconstriction and reduced severity of symptoms compared to controls. This simple pharmacological study confirms the efficacy of diphenhydramine suspension in preventing histamine-induced allergic reactions. It offers pharmacy students a practical approach to formulation and basic pharmacodynamic evaluation.

**DESIGN AND OPTIMIZE A BILAYER TABLET OF ANTIHYPERTENSIVE DRUGS USING A 32 FACTORIAL DESIGN**

Dr. Kadu Pooja Vijay

This research aimed to aimed to develop a bilayer tablet of telmisartan and Cilnidipine using a factorial design approach. Telmisartan is an angiotemin II receptor antagonist, while Cilnidipine is a calcium channel blocker. By combining these drugs in a bilayer tablet, the physicochemical differences between them could be overcome, reducing the need for frequent dosing. The compatibility of the active ingredients and excipients in each layer is critical to the success of a bilayer tablet. One of the major challenges of bilayer tablet formulation is ensuring that the two layers remain separate and do not mix during manufacturing, storage, or handling. The tablet was formulated using Croscarmellose sodium and sodium starch glycolate as super disintegrates for the Telmisartan layer, and HPMC K-100M, methylcellulose, and dicalcium phosphate for the Cilnidipine layer. The optimized batch of immediate release F7 showed 95.51% drug release, while the sustained-release FS batch showed 96.46% drug release. Compatibility studies using FTIR and different scanning calorimetry analyses confirmed compatibility between drug and excipients. Evaluation tests, including tablet dimension, dimer hardness, friability, weight uniformity, drug content, and in-vitro dissolution, yielded satisfactory results, indicating the potential effectiveness of the optimized bilayer tablet for treating hypertension.

**Keywords:** Bilayer tablet, HPMC K100m, Telmisartan, Cilnidipine, Factorial design

**FORMULATION AND OPTIMIZATION OF AMIDATED PECTIN NANOPARTICLES OF MESALAMINE FOR TARGETED COLON DELIVERY IN ULCERATIVE COLITIS**

Debjyoti Chakraborty, Oendrila Das, Shaila A Lewis
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal, Karnataka, India- 576104.
thedebjyotichakraborty@gmail.com

Ulcerative colitis is a persistent inflammatory condition limited to the colon and rectum, marked by mucosal ulceration and oxidative stress. Mesalamine remains the first-line therapy for mild to moderate cases, but conventional delivery systems are prone to premature drug release and require higher doses, resulting in increased side effects. In this study, polysaccharide (amidated pectin) nanoparticles of mesalamine were created using ionotropic gelation with calcium chloride, and formulation parameters were optimized using a Box Behnken design to maximize drug entrapment and control release. The optimized nanoparticles had an average size of 534 nm and achieved 73% entrapment efficiency. Drug release studies showed minimal leakage under acidic conditions and pronounced release in simulated colonic fluid. Structural and compatibility analyses confirmed amorphization of the drug and stable incorporation within the matrix. In vivo pharmacokinetic studies in rats indicated significantly higher and sustained mesalamine concentrations in colon tissue from the nanoparticles compared to conventional suspension. Additionally, rats treated with the nanoparticle formulation exhibited enhanced antioxidant enzyme activities including catalase, glutathione, and superoxide dismutase as well as reduced oxidative stress markers such as nitrite and malondialdehyde. These results demonstrate that amidated pectin nanoparticles effectively target mesalamine to the colon, improving local bioavailability and therapeutic efficacy while minimizing systemic exposure. The study supports the potential of this nanocarrier system as a promising strategy for improved management of ulcerative colitis.

**Keywords:** Colon-targeted drug delivery, Mesalamine nanoparticles, Amidated pectin, Ulcerative colitis, Antioxidant activity

**PC-623**

**DEVELOPMENT, OPTIMIZATION AND CHARACTERIZATION OF NIOSOMES BASED DRUG DELIVERY SYSTEMS FOR SURGICAL WOUNDS**

POOJA M RAJ

Surgical wounds need gentle and effective care so they can heal fast and stay free from infection. This study explains how niosomes, which are tiny bubble-like carriers made from safe surfactants, were developed and optimized to deliver medicine directly to surgical wounds in a better way. First, different niosome formulations were prepared by changing ingredients like surfactant type, cholesterol amount and hydration conditions. These factors were adjusted to get niosomes that were small, stable and able to hold the drug properly. The prepared niosomes were then checked for size, shape, drug-entrapment efficiency, surface charge and stability. Tiny particles were observed under special microscopes to confirm that they were round and uniform. The drug release pattern was also studied to see how slowly and steadily the medicine came out from the niosomes. The best formula released the drug in a controlled way, which is helpful for keeping the wound moist, protected and supplied with medicine for longer time without repeated applications. Tests on wound models showed that the niosome-based system improved healing, reduced inflammation and helped form healthy tissue faster compared to normal formulations. Because niosomes can stick gently to the skin and protect the drug from breaking down, they can make wound care easier and more comfortable for patients. Overall, the study shows that niosome drug delivery systems can be a promising and friendly method to support surgical wound healing. More studies will help improve them further and check their safety for wider use.

**SMART GOLD: HISTIDINE-LINKED NANOPARTICLES FOR NEXT-GEN DRUG DELIVERY**

Anshul, Pooja M Raj, B. Behera, Gaurav K Jain
Department of Pharmaceutics, DIPSAR, Delhi Pharmaceutical Sciences and Research University (DPSRU), New Delhi-110017, India.

In this study, gold nanoparticles (GNPs) were surface functionalized with dithiocarbamate (DTC) derivatives of amino acids to explore their potential as nanoscale carriers. Histidine (His) was selected as a model ligand and converted into its DTC salt by reaction with carbon disulfide under alkaline and low-temperature conditions. The reaction progress was monitored by instant thin-layer chromatography using methanol:chloroform (9:1) as the mobile phase. The reaction

ISBN: 978-81-980623-8-3

parameters like pH, temperature, time, and reactant concentrations were optimized to achieve a high yield. The His-DTC derivative was obtained as a yellow-brown solid with an 87% yield. Formation of the DTC moiety was confirmed by characteristic absorption peaks at 260 nm and 290 nm in UV–visible spectroscopy, N–C, S–S, and S–C–S stretching vibrations in FTIR spectra, a signal at 214.04 ppm in the ^13C NMR spectrum, and a parent ion at m/z 232 in mass spectrometry. In the consecutive step, gold (III) ions were reduced to form GNPs, which were then conjugated with His-DTC. The resulting His-DTC–GNP nano-conjugates were characterized by UV–visible spectroscopy, FTIR, and transmission electron microscopy, confirming successful functionalization and nanoscale morphology. The strong bidentate binding of the DTC group stabilized the gold nanoparticles and facilitated effective histidine conjugation. This approach highlights the potential of DTC chemistry for stable and efficient anchoring of biomolecules to metallic nanostructures. The His-DTC–GNP conjugates provide a versatile platform for developing targeted nanocarriers, with potential applications in drug delivery, biosensing, and biomedical nanotechnology.

## FAST-DISSOLVING NANOSUSPENSION FILMS FOR SCHIZOPHRENIA: A PATIENT-CENTRIC APPROACH TO LURASIDONE DELIVERY

Chinmayi SyamKishan.k, Dr.Suma.R, Dr.Tanushree Chakraborty, Mrs.Aisha Khanum
Department of Pharmaceutical Sciences, Al-Ameen College of Pharmacy, Hosur Road, Banglore-560027, India.
chinmaysyam@gmail.com

In the current research, nanosuspension-based oral dissolving films (ODFs) of Lurasidone HCl, a BCS Class II antipsychotic drug, were formulated with the objective of enhancing solubility, bioavailability, and patient compliance in the treatment of schizophrenia. Nanosuspensions were prepared using High Pressure Homogenization by screening various stabilizers, among which Poloxamer 407 was selected based on particle size and polydispersity index (PDI). The optimized nanosuspension was incorporated into ODFs using the lyophilization technique. Hydroxypropyl methylcellulose (HPMC E15) and glycerine were selected as the film-forming polymer and plasticizer, respectively, based on preliminary screening studies. The freeze-dried oral dissolving films of Lurasidone HCl demonstrated rapid disintegration, enhanced drug release (96.11% at 15 minutes), and superior performance compared to both heat-dried and marketed formulations. This fast-acting, easy-to-administer dosage form improves bioavailability and offers greater convenience, making it highly beneficial for patients with schizophrenia by supporting better adherence and therapeutic outcomes.

**Keywords:** Lurasidone HCl, Nanosuspension, ODFs, Freeze dried, solvent casting.

## DESIGN, DEVELOPMENT AND EVALUATION OF LIPOSOMAL DRUG DELIVERY FOR BRAIN DISORDERS

Mrs. P M M Naga Lakshmi Varma 1* and Dr. J. Subba Rao 2
1*Research Scholar, Department of Pharmaceutics, Acharya Nagarjuna University.
2 Associate Professor, HOD, Department of Pharmaceutical Chemistry, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences.
nagapmm285@gmail.com

Oxcarbazepine is an antiepileptic drug used primarily for the treatment of partial and generalized seizures. It acts by stabilizing hyperexcited neuronal membranes and inhibiting repetitive neuronal firing. Despite its effectiveness, Oxcarbazepine has limited brain bioavailability due to poor permeability across the blood-brain barrier. Advanced drug delivery systems, such as liposomes, are being explored to enhance its CNS targeting. In this study, a liposomal drug delivery system for Oxcarbazepine was developed and optimized using the Box-Behnken Design (BBD), a response surface methodology approach, to overcome these limitations. Three key formulation variables—phospholipid concentration, cholesterol content, and drug-to-lipid ratio—were selected as independent factors, while encapsulation efficiency (%EE), particle size (nm), and cumulative drug release over 24 hours (%CDR) were evaluated as dependent responses. BBD generated 17 experimental runs, and statistical analysis confirmed a significant quadratic model ($p < 0.05$) for all responses. The optimized liposomal formulation exhibited an encapsulation efficiency of 86.2%, particle size of 139.6 nm, zeta potential of –27.1 mV, and 24-hour cumulative drug release of 74.3%, indicating efficient encapsulation, colloidal stability, and sustained release. Transmission electron microscopy revealed uniform, spherical vesicles. Oxcarbazepine liposomes offer a promising strategy for targeted and sustained delivery in the management of epilepsy and related brain disorders. Further In-vivo studies are recommended for therapeutic purpose.

**Keywords**: Oxcarbazepine, Box-Behnken Design, Transmission electron microscopy.

## "INNOVATING ELDERLY CARE: A PATIENT-FRIENDLY ORODISPERSIBLE BLADDER TABLET OF MIRABEGRON"

Shubhashini J, Dr. Tanushree Chakraborty, Dr. Suma R, Mrs. Aisha khanum
Department of Pharmaceutics, Al-ameen college of pharmacy, Bangalore, Karnataka,
India -560027
Shubhashinijkyadav@gmail.com

Overactive bladder (OAB) is a common disorder among elderly patients, often accompanied by discomfort, frequent urination, and reduced quality of life. Mirabegron, a novel β3-adrenoceptor agonist, is an effective treatment option but exhibits low bioavailability (25–40%) and is generally available as conventional tablets, which can be difficult to swallow for geriatric patients suffering from dysphagia. To overcome these limitations, the present research focused on developing and optimizing a patient-friendly lyophilized Orodispersible tablet (ODT) of Mirabegron. The freeze-drying technique was employed, and a Box–Behnken design was used for formulation optimization. Gelatin (X1), Mannitol (X2), and Menthol (X3) were selected as independent variables, while disintegration time (R1) and percentage drug content (R2) were dependent variables. The prepared formulations were evaluated for friability, weight uniformity, wetting time, in-vitro disintegration time, and dissolution behavior. Among all, the F7 batch was optimized, showing a disintegration time of 9 seconds and 97% drug content. In-vitro dissolution studies revealed significantly faster drug release compared to the pure drug, with 45.9% in phosphate buffer (pH 6.8) at 15 minutes and 97.1% in 0.1N HCl buffer at 16 minutes. These findings highlight that the lyophilized Mirabegron ODT is not only effective in enhancing drug dissolution but also highly convenient for elderly patients due to its rapid disintegration and ease of administration, making it a promising and innovative patient-centric approach to improve compliance, therapeutic performance, and overall quality of geriatric care.

## INNOVATIVE MUCOADHESIVE MICROSPHERES FOR PROLONGED THIOCOLCHICOSIDE RELEASE

Nazish Patel, Pratik Padmakar Patil and M P Venkatesh
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, Karnataka, India.
nazishpatel21@gmail.com

Microsphere-based drug delivery systems have gained attention as effective tools to overcome the limitations of conventional oral pharmacotherapy. Muscle relaxant therapies often face rapid drug metabolism, which reduces clinical effectiveness and patient convenience. Thiocolchicoside, despite its therapeutic potential, suffers from poor oral bioavailability, creating a need for advanced delivery approaches. To address this, the present study developed a novel mucoadhesive microsphere system designed to enhance gastric retention and achieve sustained drug release. Sodium alginate was employed as the primary polymer, with chitosan and carbopol 934P incorporated to improve mucoadhesion, swelling, and gastric residence time. Five formulations (F1–F5) were prepared by varying polymer concentrations. The microspheres obtained were pale yellow, spherical,

ISBN: 978-81-980623-8-3

and exhibited good flow properties, with an overall production yield of 69.23%. Among all formulations, F5 demonstrated the highest entrapment efficiency (91.22%), attributed to increased viscosity from higher chitosan and carbopol levels. Swelling studies in phosphate buffer (pH 7.4) revealed greater swelling with higher polymer content, with F5 reaching 95.4%. In vitro drug release studies further confirmed that F5 provided the most controlled and sustained release of Thiocolchicoside over time. Overall, formulation F5 emerged as the most promising candidate, combining superior mucoadhesion, entrapment efficiency, swelling behavior, and sustained release. This optimized system not only addresses the bioavailability challenges of Thiocolchicoside but also offers potential as a platform technology for developing sustained-release formulations of other drugs, ultimately improving therapeutic efficacy and patient compliance.

## DEVELOPMENT AND EVALUATION OF TRANSDERMAL BIOADHESIVE SPRAY CONTAINING ESSENTIAL OIL FOR THE TREATMENT OF ACNE

Riya Bharat Lolayekar, Dr. (Mrs.) Shilpa Bhilegaonkar*
P.E.S's Rajaram and Tarabai Bandekar College of Pharmacy, Farmagudi, Ponda, GOA - 403001
shilpabhilegaonkar@gmail.com

Acne vulgaris (acne) is one of the most prevalent dermatological diseases in the world. It is a chronic inflammatory disease of the Pilosebaceous unit. It affects upto 85% of teenagers and can occur in any age group persisting into adulthood. Conventional agents that target multiple pathological processes belongs to synthetic agents with various side effects, therefore, use of alternative and complementary therapy is recommended. One of the therapies can include use of essential oil for the treatment of acne. The aim of the present study was to develop and evaluate a transdermal bio adhesive spray containing essential oil for treatment of acne vulgaris. Standardization of oil was done by HPTLC method. Suitable carrier system with various oils , surfactant and cosurfactant to be incorporated in SMEDDS was selected based on solubility / miscibility on essential oil . Thermodynamic stability testing was carried out to test the best prototype formulation. SMEDDS is formulated in order to increase the oil solubility and permeability via skin. Bioadhesive spray by incorporating bioadhesive polymers was developed to improve residence time. Precautions to maintain drug release through SMEDDS patches were evaluated. The formulation was evaluated with skin irritancy test to check suitability for application on skin. Results obtained at various formulation stage specific evaluation parameters were within acceptable ranges. This concludes that bioadhesive spray with essential oils is a good alternative for treatment of acne rather than using synthetic agents.

**Keywords**: Acne vulgaris, Propionibacterium acnes, Essential oil, Transdermal Bio adhesive spray, SMEDDS

## FORMULATION AND EVALUATION OF MOUTH DISSOLVING FILM CONTAINING MELOXICAM & RIZATRIPTAN

Vemula prasanth,patibandla Jahnavi
Kvsr Siddhartha college of pharmaceutical sciences
vemulaprasanth9261@gmail.com

Patient compliance is a major concern in pharmaceutical research, encouraging the development of novel oral dosage forms that do not require water. Mouth-dissolving films (MDFs) are gaining attention for their rapid disintegration, ease of use, and improved bioavailability. Meloxicam, a poorly water-soluble NSAID (BCS Class II), has limited dissolution and delayed therapeutic onset, while Rizatriptan, a serotonin (5-HT1B/1D) agonist (BCS Class I), is highly water soluble and rapidly absorbed. Combining these drugs in MDFs may enhance patient convenience and therapeutic efficacy. MDFs were prepared by solvent casting using hydroxypropyl methylcellulose (HPMC-15 cps) and polyvinyl alcohol (PVA) as film-forming agents. Glycerin served as a plasticizer, polysorbate 80 as surfactant, menthol as flavoring agent, and aspartame as sweetener. Drugs were uniformly dispersed in the polymeric solution before casting. Films were evaluated for appearance, thickness, folding endurance, disintegration time, and in vitro drug release. The prepared MDFs showed smooth appearance, adequate mechanical strength, and flexibility. Optimized films disintegrated within 30 seconds and released both drugs completely within 1 minute. The rapid hydration and dissolution suggested suitability for oromucosal as well as gastrointestinal absorption. These properties highlight MDFs as an effective delivery platform for poorly soluble drugs like Meloxicam while ensuring fast release of Rizatriptan.

**Keywords**: Mouth-dissolving films, Meloxicam, Rizatriptan, HPMC, solvent casting.

## AN INJECTABLE CUBOSOMES BASED DELIVERY SYSTEM FOR TREATMENT OF AGE-RELATED MACULAR DEGENERATION

M P Venkatesh, Purnima Sinha, Amulya Sharon
Dept of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, SS Nagar, Mysuru-570015, Karnataka
venkateshmpv@gmail.com

Age-related macular degeneration (AMD) is a major cause of irreversible central vision loss, with existing therapies limited by frequent invasive injections and poor bioavailability. This study aimed to design Rosuvastatin-loaded cubosomes (RSV-cubosomes) as a sustained, non-irritant ocular delivery system. Cubosomes were prepared via a top-down approach using glyceryl monooleate and Pluronic F127 and optimized through central composite design. Characterization included particle size, polydispersity index (PDI), zeta potential, and entrapment efficiency (EE). Structural analysis was performed by FT-IR, DSC, XRD, SEM, and TEM. In vitro drug release, ex vivo permeation through goat sclera–choroid–retina, 3-month stability, and HET-CAM ocular safety studies were conducted. Optimized RSV-cubosomes exhibited particle size 108.4 nm, PDI 0.181, zeta potential −12.8 mV, and EE 92.46 ± 2.12%. In vitro release showed biphasic kinetics with 87.62 ± 0.29% cumulative release over 84 h, best fitting was Higuchi model ($R^2 = 0.967$), confirming diffusion-controlled behavior. Ex vivo permeation achieved cumulative transport of 141.09 ± 0.69 µg/cm² with permeability coefficient 0.009 cm/h and flux 18.15 µg/cm²/h. Stability testing at 4°C revealed minimal deviations in particle size (6.5%), PDI (37%), and EE (10.9%). HET-CAM assay demonstrated irritation scores ≤ 0.9, classifying the formulation as non-irritant. SEM/TEM confirmed uniform cubic morphology, while FT-IR, DSC, and XRD verified complete drug encapsulation and amorphization. RSV-cubosomes displayed high entrapment, sustained release, controlled permeation, stability, and ocular safety, highlighting their potential as a nanocarrier for AMD therapy with improved efficacy and patient compliance.

## EXPLORING OKRA MUCILAGE AS BIODEGRADABLE AND SUSTAINABLE TUMOUR-RESPONSIVE NANOCARRIER

Devlina Pal and Himangshu Sekhar Maji
Department of Pharmaceutical Technology, JIS University, West Bengal, India - 700109
devlina.pal2017@gmail.com

Biodegradable and sustainable natural polymers are increasingly recognized as promising substitutes for synthetic excipients in modern drug delivery. This study investigates okra (Abelmoschus esculentus) gum as a natural pharmaceutical excipient, with emphasis on its potential for novel formulation approaches in tumour therapy. Fresh okra pods were authenticated, and the gum was extracted through aqueous maceration followed by acetone precipitation. The dried gum underwent comprehensive evaluation, including organoleptic assessment, phytochemical screening, and physicochemical analysis covering pH, solubility, loss on drying, and ash value. Functional groups in okra mucilage were determined by Fourier Transform Infrared (FTIR) spectroscopy. The gum was amorphous, odourless, and light brown with excellent swelling ability. Phytochemical tests confirmed carbohydrates and mucilage, while physicochemical studies showed a pH (6.75), loss on drying (9.63%), and total ash value (7.2%), reflecting stability and purity. Solubility studies demonstrated aqueous solubility with insolubility in organic solvents. FTIR spectra revealed characteristic hydroxyl and carboxyl peaks, confirming its polysaccharide backbone. Collectively, okra gum functions effectively as a binder, disintegrant, and suspending agent, providing a sustainable, economical alternative to conventional

ISBN: 978-81-980623-8-3

excipients. Beyond these traditional uses, an innovative prospect lies in tumour microenvironment-responsive nanoparticles fabricated from okra mucilage. Such nanocarriers, engineered to respond to acidic pH and tumour-specific enzymes, could encapsulate anticancer agents like paclitaxel or doxorubicin, maintaining stability in systemic circulation while releasing their payload selectively at tumour sites. Additionally, okra mucilage's natural mucoadhesive, biocompatible, and antioxidant properties enhance retention, tolerability, and protection against oxidative stress, positioning it as a novel platform for next-generation anticancer drug delivery.

**MMUCOADHESIVE NANOSTRUCTURED LIPID CARRIER (NLC) STATISTICAL OPTIMIZATION OF NATAMYCIN DELIVERY IN THE TOPICAL MANAGEMENT OF KERATOMYCOSIS**

Ishwari Choudhary, Preeti K. Suresh, D.K. Pradhan
Raigarh College of Pharmacy, Raigarh C.G. India 496001
ishu.faith.1204@gmail.com

To design and evaluate natamycin-incorporated mucoadhesive nanostructured lipid carriers (MN-NLC) for sustained and efficient delivery to keratomycosis. This study focuses on the practical claim of the quality by design (QbD) methodology in the creation and optimization by Box-Behnken design (BBD). MN-NLC were prepared by solvent emulsification high sheer homogenization with ultra-sonification method, optimized by (BBD) with the aid of Design-Expert® Software and investigated in-vitro, ex-vivo and in-vivo studies. The mean diameter, zeta potential, and % entrapment efficiency of optimized MN-NLC were obtained to be 200 nm, 38.78 mV, and 80.10% respectively. TEM examinations were used to confirm the size and form of spheres. MN-NLC release data demonstrated that the Higuchi model (R2 = 0.988) for delayed MN-NLC release was correct. The In-vitro release studies showed 74% MN-NLC release over 12 hours. The antifungal susceptibility investigation showed that MN-NLC effectively decreased the fungus load in less time than commercial formulations. Findings of all these results, it can be said that the formulation demonstrated a sustained release pattern and a decrease in the fungal load in the affected area. MN-NLC may thus have therapeutic promise for dealing with keratomycosis after the clinical investigation in the coming days.

**Keywords:** Keratomycosis, NLC, Mucoadhesive, Box-Behnken Design, Ocular Drug Delivery, Natamycin.

suryawanshimeghraj917@gmail.com

Natural mucilage is a biodegradable, non-toxic, and eco-friendly polymer. To assess the properties, toxicity and application of a novel polysaccharide-based polymeric network. A polysaccharide-acrylamide (TGM-AM) graft copolymer was synthesized via a green, microwave-assisted method using potassium persulfate. Optimization was done based on grafting efficiency. The polymer was characterized using FTIR, DSC, H-NMR, XRD, SEM, viscosity and release studies. The method was efficient and eco-friendly. The best batch (TGM-1) showed 400% grafting and 105% efficiency. Structural analyses confirmed successful grafting. Acute toxicity tests confirmed its safety. The F2 batch show maximum release 89.96%. The polymeric network is safe and suitable for sustained drug delivery of BCS Class II and IV drugs show the sustained release effect.

**PATIENT - FRIENDLY PAIN MANAGEMENT: FREEZE DRIED IBUPROFEN NANOSTRIP FOR SUBLINGUAL DELIVERY**

Rutushana Namdeo Shastrakar *Dr. Laxmikant BORSE ,Dr. Kuldeep Vinchurkar *Sandip Institute of Pharmaceutical Sciences Nashik.
rutushanas1911@gmail.com

The objective of this project is to develop and evaluate a sublingual freeze dried nanostrip of ibuprofen as a novel pain management approach.Though Ibuprofen is widely used, causes gastric irritation and undergoes first pass metabolism, reducing its effectiveness in conventional tablet form. In this project , ibuprofen has to first be converted into a nanosuspension using high speed homogenization and ultrasonication, with Poloxamer 188 serving as a stabilizer to improve its solubility and particle stability. This nanosuspension has to be incorporated into a pullulan-based film-forming solution, consist of glycerol for flexibility, sucralose for taste masking, and SLS and citric acid to enhance permeability and saliva stimulation. The prepared solution has to be cast, frozen, and lyophilized to produce thin, porous nanostrips intended to dissolve sublingually.The nanostrips has to be undergo evaluation for weight, thickness, folding endurance, surface pH, tensile strength, and moisture uptake, along with drug content uniformity, disintegration time, and in vitro dissolution profile. Advanced studies like SEM (surface morphology), FTIR/DSC (compatibility), and particle size analysis will further characterize the formulation.This innovative system will help to deliver rapid pain relief, increased bioavailability, and improved patient convenience over Conventional ibuprofen tablets.

**Keywords:** Sublingual nanostrip, Freeze-dried film, Ibuprofen nanosuspension, Pain management First-pass metabolism bypass, Gastric irritation reduction, Lyophilization, Film casting Freezing Rapid onset of action, Improved bioavailability, Patient compliance, Novel drug delivery system

**DEVELOPMENT OF CHITOSAN FUNCTIONALIZED LIPOSOMES LOADED WITH RALOXIFENE HCL FOR BREAST CANCER THERAPY**

Chirag R I, Tarun S Kumar and H V Gangadharappa*
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, KA, India.
chiraggowdari@gmail.com

Raloxifene HCl, a selective estrogen receptor modulator (SERM), is widely used for the prevention and treatment of breast cancer. However, its poor aqueous solubility and limited oral bioavailability restrict its therapeutic potential. The present study was undertaken to develop and evaluate Raloxifene HCl loaded liposomes functionalized with chitosan for enhanced bioavailability and targeted intravenous delivery. Liposomes were prepared using the ethanol injection method with soy lecithin and cholesterol as lipid components, followed by chitosan coating to improve mucoadhesion, stability, and cellular uptake. The formulation was characterized for particle size, zeta potential, entrapment efficiency, Fourier-transform infrared spectroscopy (FTIR), differential scanning calorimetry (DSC), scanning electron microscopy (SEM), and in vitro release behavior. The optimized formulation exhibited a mean particle size of 192.6 nm, polydispersity index of 0.244, zeta potential of –21.3 mV, and entrapment efficiency of 80.79%, indicating a monodisperse and stable system. SEM confirmed spherical vesicles with uniform distribution, while FTIR and DSC analyses demonstrated compatibility between drug and excipients. In vitro diffusion studies revealed an initial burst release within the first 12 hours, followed by sustained drug release up to 24 hours. Release studies at pH 5.8 and 7.4 showed faster drug release at acidic pH, simulating the tumor microenvironment. Overall, the chitosan-functionalized Raloxifene liposomal system demonstrated promising characteristics for controlled intravenous delivery, potentially enhancing site-specific delivery to tumor tissues through improved mucoadhesion and the enhanced permeability and retention (EPR) effect. These findings suggest its suitability as a novel drug delivery approach for breast cancer therapy.

**Keywords:** Raloxifene HCl, Liposomes, Chitosan, Mucoadhesive nanoparticles.

rjvishal198@gmail.com

Wound healing is repairing of injured tissue. It is an interaction of cellular events that regenerate damaged tissue. It involves many stages such as haemostasis in which clotting factors plays major role. In migration phase granulation collagen is formed by fibroblasts and providing a rigid strength skin. Cellular connective tissue reforms in remodelling phase and strengthen the new epithelium which produces the final scar. The present work aim of investigation was to prepare and evaluate multiphase hydrogel system incorporated with silver oxide nanoparticles for wound healing. The silver oxide loaded hydrogel were prepared by taking chitosan, PEG and hyaluronic acid at different ratio. Prepared hydrogels were characterized on the given parameters of surface morphology, water vapour transmission rate (WVTR), swelling ratio, hemocompatibility, stability, in-vitro release and in-vivo studies. The results were significant and reliable compared to other prepared formulations. The objective of proposed work was satisfied by prepared delivery system for the treatment of cutaneous wounds.

**Keywords:** Chitosan, Hyaluronic acid, silver oxide, PEG, heparin.

## DEVELOPMENT AND OPTIMIZATION OF TOPICAL FILM FORMING GEL OF MUPIROCIN IN THE TREATMENT OF IMPETIGO

Suwarna Suresh Bobde1, Tejal Naik1, Mangirish Deshpande2
1 Department of Pharmaceutics, P.E. S's Rajaram and Tarabai Bandekar College of Pharmacy, Ponda, Goa. India.403401
2 Department of Pharmacology, P.E. S's Rajaram and Tarabai Bandekar College of Pharmacy, Ponda, Goa. India.403401
suwarnartbcop@gmail.com

Impetigo is a highly contagious bacterial superficial skin infection caused by Staphylococcus aureus and Streptococcus pyogenes in children. The topical antibiotic mupirocin is used to treat skin infections like impetigo. This study focuses on the preparation of Mupirocin-based Film Forming Gel (FFG) for the treatment of impetigo. Design of Experiments (DoE) approach was used for the study where in 12 formulations were prepared using a two factor two level, Central Composite Design (CCD) with four centre points. The independent variables used were concentration of Eudragit L-100 and concentration of Hyaluronic acid and the dependent variables used were drying time in seconds and drug release at the end of 6hrs. The formulations were evaluated for parameters such as pH, viscosity, spread ability, film-forming ability, drying time, washability, antimicrobial studies, invitro drug release and stability study. The optimised formulation was tested on animals for skin irritation study.The optimized formulations demonstrated faster drying time favourable drug release with no skin irritation, edema on animal skin demonstrating its dermatological safety. The prepared film forming gels of mupirocin were found to be promising alternative for effective treatment of impetigo offering improved performance, safety, and user convenience.

**Keywords:** Mupirocin, Film Forming Gel, Impetigo, Central Composite Design

## DEVELOPMENT OF A COST-EFFECTIVE EFFERVESCENT PROBIOTIC TABLET USING BACILLUS CLAUSII SPORES AS A LOW-COST ALTERNATIVE TO ENTEROGERMINA SUSPENSION.

Mangesh Suresh Mali Kuldeep Vinchukar Laxmikant Borse
Sandip Institute of Pharmaceutical Sciences Nashik
Sandip Foundation Nashik Mahiravani

The present study focuses on the development of a cost-effective effervescent probiotic tablet containing Bacillus clausii spores as a novel alternative to conventional probiotic suspensions like Enterogermina. Commercial formulations are often expensive, require cold chain storage, and come in single-use vials, limiting their accessibility in low-resource settings. This project proposes a shelf-stable, portable, and patient-friendly effervescent tablet, formulated to deliver ≥2 billion CFU of Bacillus clausii per dose. The formulation includes citric acid and sodium bicarbonate as effervescent agents, mannitol as filler, and natural flavors for improved palatability. The spores are cultured, harvested, and dried using lyophilization or spray drying to retain viability. Tablets are prepared via direct compression and packaged in moisture-resistant containers.The product undergoes physical (effervescence time, weight uniformity), microbiological (CFU count, contamination), and chemical (pH, moisture content) evaluations. Stability studies are conducted as per ICH guidelines, indicating an expected shelf life of 12–18 months. The projected cost is ₹10–₹15 per dose — significantly lower than current market options.The proposed effervescent format offers a novel, child-friendly, and scalable solution for probiotic delivery, with strong potential for use in pediatric, rural, and travel-based healthcare settings.

**Keywords:** Bacillus clausii, Probiotic, Effervescent tablet,Cost-effective formulation, Gut microbiota, Spore-forming bacteria, Shelf-stable probiotic, Enterogermina alternative, Oral dosage form, Pediatric formulation.

## DRUG UTILIZATION EVALUATION OF MEDICATIONS USED IN THE MANAGEMENT OF NEPHROLOGICAL DISORDERS WITH RESPECTIVE OF CKD & AKI: A HOSPITAL BASED PROSPECTIVE COHORT STUDY

Chinchili Pramilarani and Shaik Farahan Subahan
Department of PharmacyPractice,
Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
pramilachinchili@gmail.com

Nephrological disorders, including acute kidney injury (AKI) and chronic kidney disease (CKD), are often referred to as "silent killers". Despite their significant impact, they are notably absent from the World Health Organization's (WHO) list of five major non-communicable diseases (NCDs) driving premature death and disability. AKI increases the risk of CKD, and vice versa. In resource-poor settings with weak primary care, as many as 9 out of 10 individuals with CKD are unaware, they have the condition and do not seek treatment. A hospital-based prospective cohort study was conducted to evaluate drug utilization in the management of nephrological disorders. The study included a total of 150 patients. The most frequently prescribed drug was Pantoprazole (12.02%). Among antihypertensive medications, Cilnidipine had the highest usage (7.92%). Diuretics were widely prescribed (8.35%), with Furosemide being the most common (100 prescriptions). The study also found that CKD Stage II was the most commonly reported burden among patients. The most commonly prescribed drugs overall were Pantoprazole, Aspirin, and Atorvastatin. The study concluded that the prescribing patterns in the Nephrology Department were in accordance with WHO criteria. However, polypharmacy was common due to the presence of comorbid conditions. The authors suggest that a clinical pharmacist in a multidisciplinary team can optimize drug therapy through medication use evaluations and patient education, ensuring rational drug prescribing and improved clinical outcome

## A COMPARATIVE INTERVENTIONAL STUDY ON DRUG-RELATED PROBLEMS IN GERIATRIC PATIENTS USING START/STOPP CRITERIA: ROLE OF CLINICAL PHARMACIST COUNSELING IN ENHANCING MEDICATION APPROPRIATENESS, ADHERENCE, AND QUALITY OF LIFE

M Shiva Rama Krishna1, Mrinmoy Basak2, A. Shyam Sunder3
princeshivayahoo@gmail.com
Department of Pharmacy Practice, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya. Hyderabad, Telangana, 500017.
Department of Pharmacology, AdtU, Guwahati, Assam
Department of Pharmacology, Balaji Institute of Pharmaceutical Sciences, Warangal.

Geriatric patients are highly susceptible to drug-related problems (DRPs) due to polypharmacy, comorbidities, and age-related pharmacokinetic changes. The application of START/STOPP criteria helps identify potentially inappropriate medications (PIMs) and optimize therapy. A hospital-based pre–post comparative interventional study was conducted among geriatric outpatients (>65 years). A total of 304 patients (sample may vary) were enrolled and allocated into interventional (n=106) and non-interventional (n=72) groups. Data included demographics, medication history, pill count adherence, and

ISBN: 978-81-980623-8-3

WHOQOL-BREF scores. START/STOPP criteria were applied to detect PIMs, and clinical pharmacists provided individualized counseling on medications, adherence, and lifestyle modifications to the intervention group. Statistical analysis was performed using the t-test and one-way ANOVA. Overall, 183 DRPs were identified, with 133 STOPP-related and 50 START-related. DRPs were most frequent in the cardiac department and least in the urogenital/endocrine. START-related DRPs were highest in cardiac cases, while STOPP-related DRPs were most common in CNS disorders. Pharmacist intervention significantly improved adherence (pill count), reduced DRPs, and enhanced quality of life scores, particularly in physical and psychological domains. Educational status was positively associated with better knowledge and adherence ($p<0.05$). Pharmacist-led interventions using START/STOPP criteria effectively improve medication appropriateness, adherence, and quality of life in geriatrics. Integration of pharmacists into routine geriatric care can minimize DRPs and strengthen long-term clinical outcomes.

## THERAPEUTIC POTENTIAL OF META-COMPLEX HYDROGEL IN ACCELERATING WOUND REPAIR

Pooja Patra, Ishwari Choudhary, Bhavesh Yadav, D. K. Pradhan
Raigarh College of Pharmacy, Raigarh (C.G.) India- 496001
patrapooja755@gmail.com

Wound healing is a complex biological process involving hemostasis, inflammation, proliferation, and tissue remodeling. Recent advances in biomaterials have highlighted the potential of hydrogel-based dressings due to their high water content, biocompatibility, and ability to create a moist wound environment conducive to tissue repair. Meta-complex hydrogels, developed by incorporating metal ions or metal-based complexes within a polymeric network, exhibit multifunctional properties that enhance the wound healing process. These hydrogels not only provide structural support but also deliver antimicrobial, anti-inflammatory, and angiogenic effects through controlled release of metal ions such as zinc, copper, or silver. Their tunable physicochemical characteristics, including porosity, swelling ability, and mechanical strength, enable efficient oxygen exchange and exudate absorption while minimizing infection risks. Furthermore, meta-complex hydrogels can be engineered for sustained drug delivery, thereby accelerating cell proliferation, collagen deposition, and re-epithelialization. Collectively, these properties position meta-complex hydrogels as a promising next-generation wound dressing with significant clinical potential in managing chronic and acute wounds.

**Keywords:** Meta-complex hydrogel, wound healing, biomaterials, drug delivery, antimicrobial activity.

## FORMULATION AND EVALUATION OF ASPIRIN LOADED MICROSPONGE CAPSULE FOR ANTI-INFLAMMATORY ACTIVITY

V. Arunachalam1*, M. Jayakumar2 and Dr. G. Mariyappan3
Department of Pharmaceutics, Pallavan pharmacy college, Kanchipuram-631502.
Professor in Department of Pharmaceutics, Pallavan Pharmacy College, Kanchipuram-631502.
arunsivalingashcheyyar@gmail.com

This research focused on preparing and evaluating aspirin loaded microsponges in capsule form to deliver the anti-inflammatory drug with controlled release , improved stability, and enhanced bioavailability. A microsponge was a polymeric drug delivery system consisting of microscopic spherical and porous particles that can trap active ingredients. The ethyl cellulose were used to create the polymeric microsponge. The microsponge capsules containing porous microparticles with a “bag of marbles” internal structure were formulated to utilizing techniques like biphasic - liquid mixture polymerization or virtual - emulsion osmosis method. The formulated polymeric microsponges was used to observe the presence of porous by using techniques as field emulsion scanning electron microscopy (FESEM) and evaluated through drug content, test tube experiments and particle size studies. The typical size of microsponge particles are 25-30µm containing porus with volume of 0.5-1 g/ml. The microsponges encapsulated in size 1 capsules for their anti-inflammatory effect, to showing good entrapment efficiency and positive results for anti-inflammatory effects. These studies are focused on optimizing the capsule formulation to estimate the release of rate of aspirin from the microsponges. These amount of drug entrapped was determined with high entrapment efficiency values ranging from (79.15% to 87.5%) and demonstrated controlled aspirin release, leading to improved bioavailability and reduced side effects. They indicates that the microsponge capsules system releases aspirin drug over time, revealing a positive anti-inflammatory impact within the body.

## LIPOSOMAL ENCAPSULATION OF HERBAL EXTRACTS: A NOVEL STRATEGY TO ENHANCE STABILITY AND BIOAVAILABILITY

Sucharita Gangikunta, P. V Durga Seshu Priya
Pharmaceutical Chemistry Division, Jagan’s Institute of Pharmaceutical Sciences, Nellore, Andhra Pradesh. Nellore, Andhra Pradesh, India.
sucharitavenkata@gmail.com

Herbal medicines have gained worldwide importance due to their wide range of pharmacological effects. However, their therapeutic effectiveness is often limited by poor solubility, instability under physiological conditions, and low bioavailability. Nanotechnology-based delivery systems, especially liposomes, provide a promising way to overcome these issues. This study aimed to develop and characterize liposomal formulations containing standardized herbal extracts rich in bioactive phytochemicals. Liposomes were prepared using the thin-film hydration method followed by sonication to produce nanosized vesicles. Dynamic light scattering and transmission electron microscopy showed spherical particles with an average size below 200 nm, a narrow size distribution, and high encapsulation efficiency. Stability tests indicated that liposomal encapsulation effectively protected the extracts from degradation under stress conditions. In vitro antioxidant tests, including DPPH and ABTS radical scavenging assays, showed enhanced activity of liposome-loaded extracts compared to free extracts. Additionally, antimicrobial tests against common bacterial and fungal strains demonstrated increased inhibition zones and lower minimum inhibitory concentrations, confirming improved bioactivity with liposomal delivery. The better performance was attributed to improved solubility, protection from enzymatic breakdown, and increased cellular uptake of phytochemicals. These results suggest that liposomal encapsulation is a viable strategy to boost the pharmacological potential of herbal extracts and could lead to the development of new herbal nanomedicines with better therapeutic effectiveness and patient adherence.

**Keywords:** Herbal extracts, Liposomes, Phytochemicals, Bioavailability, Antioxidant activity, Nanocarriers, Drug delivery

## TO FORMULATE AND EVALUATE MESALAMINE-LOADED CYCLODEXTRIN-BASED NANOSPONGES AS A SOLID ORAL FORMULATION

GAWAI ASMITA ASHOKRAO, PATIL KAJAL DEORAM, MR. NILKAMAL WAGHMARE*
BHARATI VIDYAPEETH’S COLLEGE OF PHARMACY, SECTOR 8, C.B.D BELAPUR, NAVI MUMBAI – 400614.
nilkamal.waghmare@bvcop.in

The present research focuses on the formulation and characterization of a novel drug delivery system using cyclodextrin-based nanosponges (CDNS) as an efficient carrier for poorly water- soluble drugs. Conventional oral drug delivery faces challenges such as low solubility, poor permeability, and reduced bioavailability, particularly for Biopharmaceutical Classification System (BCS) class II and IV compounds. To overcome these limitations, nanosponges, consisting of cross- linked cyclodextrin polymers, were synthesized to enhance solubility, stability, and controlled release of therapeutic agents. Various methods including solvent evaporation, melt technique, and ultrasound-assisted synthesis were employed for nanosponges preparation. The synthesized formulations were evaluated using advanced characterization techniques such as Fourier Transform Infrared Spectroscopy (FTIR), Differential Scanning Calorimetry (DSC), Powder X-Ray Diffraction (PXRD), and Scanning Electron Microscopy (SEM) to confirm molecular interactions, crystallinity, morphology, and thermal stability. Drug

ISBN: 978-81-980623-8-3

loading and entrapment efficiency were determined, demonstrating significant improvement in encapsulation capacity. In vitro release studies showed sustained and controlled drug release, indicating potential application in enhancing oral bioavailability and therapeutic efficacy. This study highlights the versatility of CDNS in delivering both hydrophilic and hydrophobic drugs while ensuring safety, stability, and biocompatibility. The findings offer valuable insights into the development of advanced drug delivery platforms, potentially transforming therapeutic outcomes for drugs with poor water solubility, thereby paving the way for future clinical applications.

priyakeerthi2808@gmail.com

To formulate and estimate the dental mucoadhesive gel containing a ethanolic bark extract of Vachellia Nilotica for treating tooth pain.The dental gel was prepared by using carbopol 940, sodium carboxy methyl cellulose, propylene glycol, hydroxy methyl cellulose and clove oil. The Vachellia Nilotica extract was to be prepared with ethanol and water ratio is (80:20v/v). The optimized studies were diffusion study , stability testing, drug content determination for the release of drug that contain percent cumulative study from gel formulation and present activity studies. The dental gel formulation was evaluated for different organoleptic properties such as pH, viscosity, Spreadability and phytochemical screening. Mucoadhesive gel strength was measured and in-vitro studies of anti-microbial activity and drug realease. This studies were carried out the two same formulation contain sodium carboxy methyl cellulose as a polymer and carbopol. The various concentration of Carbopol was prepared at different form of formulation. In-vitro antimicrobial activity of extract showed a zone of inhibition was done on Mueller-Hinton agar (MHA) against the gram positive bacteria of streptococcus aureus (S . aureus) by using disc diffusion method. The estimation of parameters that indicate the optimized batch to prepared mucoadhesive gel was stable, good drug delivery system containing the antimicrobial activity for prevention of periodontitis, tooth pain, dental caries. The drug content was to be found at 80% to 85% of given extract. The force range from 3432.9 to 3756.1 dyne/cm2. The drug release cumulative of in-vitro study within 90% to 94%. Based on a in-vitro evaluation of mucoadhesive gel, it was selected as the best formulation.

**Keywords**: Vachellia nilotica, Aerial parts, Clove oil, Anti-microbial activity, Mucoadhesive dental gel, Carbopol, Sodium CMC, HPMC.

## BRAIN-TARGETED T-RESVERATROL NANOEMULSIONS IN MEMORY MODELS

Wamankar Suchitaa*,, Gupta Anshitab, Kaur Chanchal Deepc
aShri Rawatpura Sarkar Institute of Pharmacy, Kumhari, Durg, Chhattisgarh, 490042, India.
bDepartment of Pharmacy, Guru Ghasidas Vishwavidyalaya, Bilaspur,495009, Chhattisgarh,India
cRungta College of Pharmaceutical Sciences and Research, Nandanvan, Raipur,Chhattisgarh, 492099,India

The present study investigates the memory-enhancing potential of lactoferrin-conjugated Resveratrol-loaded nanoemulsions (Lacto-T-Res-NEs) compared with T-Resveratrol nanoemulsions (T-Res-NEs) in mice. Nanoemulsions were prepared by high-energy emulsification and characterized for size (120–150 nm), polydispersity index (0.21), and zeta potential (–28 mV). The in vivo effects were assessed using the Elevated Plus Maze (EPM) and locomotor activity tests. In the EPM, transfer latency (TL), an indicator of learning and memory, was significantly reduced in Lacto-T-Res-NE treated mice (Day 1 TL: 42.5 ± 3.1 s; Day 2 TL: 18.7 ± 2.4 s) compared to T-Res-NEs (Day 1: 44.8 ± 3.6 s; Day 2: 26.4 ± 3.2 s) and control (Day 1: 47.2 ± 4.1 s; Day 2: 39.6 ± 3.8 s) groups ($p < 0.01$). The percentage reduction in TL from Day 1 to Day 2 was highest in the Lacto-T-Res-NE group (55.9%) compared to T-Res-NEs (41.1%) and control (16.1%). Locomotor activity, measured as total ambulation in an open field, showed no significant difference between groups (Control: 275 ± 18 counts; T-Res-NE: 282 ± 21; Lacto-T-Res-NE: 289 ± 19; $p > 0.05$), confirming that memory improvement was not due to changes in motor activity. These findings suggest that lactoferrin conjugation enhances the brain-targeting efficiency of T-Resveratrol nanoemulsions, leading to superior memory-enhancing effects without altering locomotor behavior. Lacto-T-Res-NEs may offer a promising nanocarrier strategy for neuroprotective therapeutics.

**Keywords:** T-Resveratrol, lactoferrin, Nanoemulsion, memory, Elevated Plus Maze, locomotor activity.

## DESIGN AND DEVELOPMENT OF MICROSPHERES-BASED TOPICAL DRUG DELIVERY SYSTEMS

Aluri Murali*, Patibandla Jahnavi
KVSR Siddhartha College of Pharmaceutical Sciences,Vijayawada,Andhra Pradesh,India-520010
muralialuri554@gmail.com

The objective of this study was to design and evaluate topical controlled-release dosage forms by incorporating drug-loaded microspheres. Tx, Ix, Cx, and Bx, classified as anti-acne agents, were selected as model drugs. Microspheres were formulated using porous polymeric microbeads with non-biodegradable polymers like silica. These microspheres were characterized using FT-IR spectroscopy and Differential Scanning Calorimetry to assess drug–polymer compatibility. The resulting microspheres were small, discrete, spherical, and free-flowing, with a mean particle size of 201.34 µm. In vitro drug release studies demonstrated that in-house formulations provided a release profile similar to that of an innovator formulation. Drug-loaded microspheres were incorporated into gel formulations, which were further evaluated for drug content and viscosity. The in vitro release profile revealed sustained drug release for up to 7 hours from gels containing Tx, Ix, and a combination of (Cx + Bx) microspheres. Model fitting analysis indicated a non-Fickian mechanism of drug release with Super Case II transport, suggesting that the release rate is governed by polymer relaxation and erosion. Stability studies confirmed no significant changes in drug content or physical appearance over the testing period, indicating good formulation stability. This study concludes that microsphere-based topical gels can offer controlled and sustained drug delivery, making them promising systems for the treatment of acne and potentially other dermatological conditions.

**Keywords:** Microspheres; Topical gels; Microbead; In-house; Innovator formulation.

## FORMULATION AND EVALUATION OF MUCOADHESIVE NANOSTRUCTURED LIPID CARRIERS FOR EFFECTIVE TREATMENT OF KERATOMYCOSIS

Priti Jaiswal, Ishwari Choudhary, D.K. Pradhan
Raigarh College of Pharmacy, Raigarh C.G. India 496001
pritij724@gmail.com

Keratomycosis, a severe fungal infection of the cornea, poses significant therapeutic challenges due to poor ocular bioavailability of antifungal drugs. Conventional treatments suffer from rapid drug elimination and limited penetration. Mucoadhesive nanostructured lipid carriers (NLCs) offer a promising alternative by enhancing drug retention and permeation at the ocular surface, thereby improving antifungal efficacy. Mucoadhesive NLCs were developed using a hot high-shear homogenization and ultrasonication technique with a lipid matrix composed of solid and liquid lipids. Natamycin were encapsulated within NLCs. Chitosan was incorporated to enhance mucoadhesion. The formulations were optimized based on particle size, polydispersity index (PDI), zeta potential, entrapment efficiency (EE), and in vitro drug release. The optimized NLCs exhibited a particle size of ~150–200 nm, a PDI of <0.3, and a zeta potential of ±30 mV, ensuring stability. High drug entrapment efficiency (>80%) was achieved, and FTIR confirmed drug-lipid compatibility. TEM revealed a spherical morphology. In vitro drug

ISBN: 978-81-980623-8-3

release followed a biphasic pattern with sustained release over 24 hours. The optimized NLCs significantly reduced fungal burden in experimental keratomycosis, suggesting improved therapeutic potential. Mucoadhesive NLCs effectively enhance ocular drug delivery for keratomycosis, providing prolonged retention, controlled release, and superior antifungal efficacy. This nanotechnology-driven approach could revolutionize keratomycosis management.

**Keywords:** Nanostructured lipid carriers, Mucoadhesion, Keratomycosis, Ocular drug delivery, Antifungal therapy.

**"TRANSFORMING CANCER CARE: NANOGEL-BASED PRECISION THERAPY FOR DERMATOFIBROSARCOMA PROTUBERANS WITH IMATINIB MESYLATE"**

Preet Prajapati*, Yash Dudhwala
Shree Naranjibhai Lalbhai Patel College of Pharmacy, Umrakh
pritprajapati444@gmail.com

Dermatofibrosarcoma Protuberans (DFSP) is a rare, locally aggressive soft tissue sarcoma driven by the PDGFB–COL1A1 fusion gene, making it highly responsive to targeted therapy. While surgical excision remains the primary treatment, cases with local recurrence, metastasis, or inoperability require alternative therapeutic strategies. Imatinib mesylate, a tyrosine kinase inhibitor, has demonstrated response rates of 50–80% in fusion-positive DFSP cases. However, systemic administration is associated with dose-dependent toxicity and suboptimal drug accumulation at the tumor site. This study focuses on the development, optimization, and characterization of an Imatinib Mesylate-loaded nanogel for localized and sustained DFSP treatment. Nanogel formulations were prepared using emulsion solvent evaporation followed by gel incorporation, ensuring enhanced drug encapsulation efficiency (EE) of 78.4 ± 2.1% and sustained drug release over 48 hours. The optimized formulation exhibited a particle size of 152.6 ± 5.3 nm, a zeta potential of -21.4 ± 1.2 mV, and a polydispersity index (PDI) of 0.162 ± 0.03, indicating stability and uniformity. In vitro cytotoxicity studies on HT-1080 human fibrosarcoma cells demonstrated a 53.7% cell viability reduction at 48 hours, confirming potent anti-proliferative effects. Additionally, ex vivo permeation studies using porcine skin models showed 3.8-fold higher retention of Imatinib in deeper dermal layers compared to conventional gel formulations. These findings suggest that the nanogel-based drug delivery system enhances localized drug accumulation, minimizes systemic exposure, and improves therapeutic efficacy, making it a promising approach for DFSP treatment, particularly in advanced and inoperable cases. Further in vivo studies will validate its clinical potential.

**"TAILORED SOLUTIONS FOR ANTICANCER DRUG DELIVERY: DESIGN, DEVELOPMENT, AND OPTIMIZATION OF A COLON-TARGETED APPROACH"**

Saloni V. Patel, Mr. Yash D. Dudhwala, Riya K. Mehta
Student at SNLPCP, Umrakh
salonipatel1544@gmail.com

Capecitabine is a chemotherapeutic agent used in the treatment of colorectal cancers and metastatic breast. Therefore, a colon targeted formulation of Capecitabine will ensure high local concentrations of drug in colon and reduce upper gastrointestinal toxicities that arise from the use of its conventional formulations. Theaim of the present study was to design and develop formulation for colon specific delivery of Capecitabine for the potential treatment of colorectal cancer. For the purpose of formulation design, a colon targeted tablet containing the drug with ligand conjugated polymer was proposed. It was expected that the use of pH sensitive polymer would ensure the drug release in the colon and the ligand conjugation would ensure the targeting of the cancerous cell. Therefore, the primary objective of the study was to develop and optimize Capecitabine loaded folic acid conjugated chitosan nanoparticles and later to develop the colon targeted tabletscontaining these optimized nanoparticles. To develop the optimized nanoparticles, Box-Behnken design (BBD) was used and the optimized batch containing 0.17 mg/mL FA-CS, 0.72 mg/mL STPP and 17.52 mg Capecitabine was selected. The optimized batch was evaluated for particle size (205.2 nm), polydispersity index (0.194), and %entrapment efficiency (77.71%). Thesenanoparticles were used to formulate the colon targeted tablets. For colon targeting, various coating parameters were evaluated and it was found to be satisfactory. The drugrelease study was performed in various medium, mimicking physiological environment,0.1N HCL pH 1.2, PBS pH 7.4, and PBS pH 6.8 which was found to be 0%, 29.06 ± 0.893%, and 96.41 ± 0.297% respectively. Furthermore, on the basis of stability studyresults, it was observed that there was no significant change in the formulationcharacteristics over the period of one month. Thus, the developed colon targeted tabletscontaining Capecitabine loaded folic acid conjugated chitosan nanoparticles were probably the best alternative approach for the treatment of patients suffering from colorectal cancer.

Sugarcane bagasse (SCB) was explored as a sustainable cellulose source, yielding 44–45% through sequential extractions, delignification with acidic sodium chlorite, and alkali treatments (10% KOH/NaOH). FTIR confirmed the structural integrity of the extracted cellulose. To develop a multifunctional system, methacrylated monocarboxylic SCB cellulose (MAMC-SBC) was synthesized and copolymerized with HPMC and Poloxamer-188 via in situ free radical polymerization using cystamine bisacrylamide (CBA). The resulting nanogels exhibited redox, pH, and thermal responsiveness, with stable particle sizes ranging from 250 to 440 nm. DOE-based optimization achieved desirable physicochemical properties. Lyophilized nanogels showed favourable morphology, swelling behaviour, and encapsulation efficiency. In vitro release demonstrated sustained drug release up to 85%, highlighting SCB-derived nanogels as an eco-friendly platform for controlled drug delivery.

**Keywords:** Cellulose, Extraction, Sugarcane Bagasse, Synthesis, Nanogel.

rarokar.npharma@gmail.com

Enhanced efficacy and reduced toxicity require targeting the malignant cells which can be done by surface functionalization of nanocarriers, such as polymeric micelles, using a block copolymer with a conjugation moiety. By blocking P-gp, this could improve the targeting capability of drug-loaded nanocarriers and prevent drug efflux. Pteroyl-Y-l-glutamate or folic acid (FA) can be used to treat cancer growth linked to a pro-tumorigenic tumor microenvironment with folate receptor (FR). Pluronic F68 has the ability to inhibit P-glycoprotein (P-gp), whereas the pteroyl-Y-l-glutamate modified carriers can target FR. Thus, the goal of our research was to create FA-linked Pluronic F68 (FA-PF68) micelles for the delivery of docetaxel trihydrate (DTX). Pteroyl-Y-l-glutamate and PF68 were linked in a preliminary manner using UV spectroscopy, and this was verified by DSC and FTIR. FA-PF68-DTX micelles were prepared by DTX encapsulation in micelles via thin-film hydration. The nanocarriers shows lower particle size (152.2 nm) and exhibits improved physical stability. FA-PF68-DTX micelles were found to have a spherical form and a higher entrapment efficiency (94.75 ± 1.89%) in SEM. During the first 24 hours, the FA-PF68-DTX and PF68-DTX micelles showed a sustained release of DTX of around 80.25 ± 1.53 % and 47.56 ± 0.89 %, respectively. When it comes to MDA-MB-231 cells with reduced vitality, the FA PF68-DTX micelles exhibit higher efficiency. According to the histopathological analysis, the FA-F68 conjugation was not harmful to lung, kidney, or liver

ISBN: 978-81-980623-8-3

cells. It demonstrated the ability of synthetic pteroyl-Y-l-glutamate/PF68 modified FA-PF68-DTX micelles to target the tumor cells' overexpressed FR.

**THE RISING SIGNIFICANCE OF NANOPARTICLES IN COSMETICS**

Jay Kumar Chandra, Aakash Gupta, D. K. Pradhan
Raigarh College of Pharmacy, Raigarh Chhattisgarh, India ,496001
jaychandrarcp@gmail.com

In the cutting-edge field of research known as nanotechnology, materials, devices, and systems are designed, characterized, produced, and used by manipulating their size and shape at the nanometer scale (1–100 nm). The use of nanotechnology in cosmetic formulation is regarded as the newest and most exciting technology on the market. For skin, hair, nails, lips, and teeth, nanocosmetics and nanocosmeceuticals have been thoroughly studied. It has been discovered that adding nanoparticles to products increases their effectiveness and customer happiness. Nowadays, nanoscale substances including cubosomes, nanodots, liposomes, dendrimers, and nanoemulsions are frequently used as ingredients in cosmetic products. The uses of nanoparticles in the cosmetics business, their special qualities, and the benefits of using nanoscale substances over non-nanoscale ones are all given particular attention. Additionally covered are the most recent methods for characterizing nanoparticles physicochemically and toxicologically.

dezney.remica@gmail.com

The main objective of the present study was to develop dexibuprofen-loaded microspheres for controlled drug release through Quality by design (QbD) approach. Microspheres are tiny spherical particles ranging from 1 to 1000 µm made from polymers. In microspheres, the dose and the frequency of administration can be reduced, which avoids the gastric irritation, gastric ulceration and other side effects associated with the conventional dexibuprofen. The microspheres were prepared by the emulsion solvent evaporation method. The Full factorial design was employed to systematically optimise the critical material attributes (CMAs) and critical process parameters (CPPs) such as PLGA concentration, PVA concentration, and stirring speed. All ten formulations of the microparticles were evaluated for particle size, %encapsulation efficiency, and % in-vitro drug dissolution study. The microsphere formulation was optimised using a numerical global desirability function of 0.93. The optimised formulation exhibited a particle size of 348.7nm with the highest entrapment efficiency and in vitro drug release of 98% and 95.2% respectively. The SEM studies on the optimised formulation showed the spherical nature of the prepared microspheres. The present study effectively utilised a quality-by-design approach to formulate controlled-release microspheres loaded with dexibuprofen. This optimised formulation exhibited controlled release of the drug, as evidenced by an in-vivo studies.

Bharati Vidyapeeth's College Of Pharmacy, Sector 8, C.B.D Belapur, Navi Mumbai – 400614.
neha.dand@bvcop.in

Oral administration is the most preferred route for drug delivery; however, nearly 40% of marketed oral dosage forms and up to 90% of new chemical entities suffer from poor aqueous solubility, resulting in low bioavailability. Aceclofenac (ACF), a widely used non-steroidal anti-inflammatory drug (NSAID) for rheumatoid arthritis and musculoskeletal disorders, belongs to the Biopharmaceutics Classification System (BCS) Class II, where solubility is the limiting factor for absorption. Preformulation studies confirmed the identity and purity of ACF using melting point, FTIR, DSC, and UV-Visible spectroscopy, followed by calibration curve construction. Among different crosslinkers, diphenyl carbonate (DPC) was selected for nanosponge synthesis based on the intensity of carbonate bond formation. Blank CDNS were synthesized using melt, interfacial polymerization, and ultrasonic probe methods, with the melt method yielding stable and amorphous particles. Optimization of formulation parameters was carried out using StatEase® Design-Expert software (Box–Behnken design), where βCD molar concentration, DPC molar concentration, and reaction time were considered as independent variables, while percent yield, particle size, and carbonate bond intensity served as responses. The optimized batch demonstrated a yield of 46.14%, particle size of ~620 nm, and strong carbonate bond formation (confirmed by FTIR peak at 1772.88 $cm^{-1}$). ACF was loaded into optimized CDNS using the incubation–lyophilization method, and encapsulation was confirmed by FTIR and DSC, which showed significant peak shifts and reduced intensity, indicative of drug entrapment within CDNS cavities. The developed ACF-loaded CDNS exhibited improved solubility, high entrapment efficiency, and potential for controlled release, which can enhance oral bioavailability, minimize dose dumping, and reduce gastrointestinal side effects associated with conventional ACF formulations. Thus, cyclodextrin-based nanosponges offer a promising strategy for the development of effective and safe oral delivery systems for poorly soluble drugs like ACF.

**Keywords**: Aceclofenac, cyclodextrin-based nanosponges, drug loading, bioavailability, FTIR, Box-Behnken design, solubility enhancement, nanosponge optimization.

**THERMORESPONSIVE GEL SYSTEM FOR TOPICAL DELIVERY OF ASPIRIN-LOADED PLGA MICROSPHERES IN DENTAL TISSUE ENGINEERING**

Litha Thomas1, Preeti Karwa 2, V Kusum Devi 3
1Department of Pharmaceutics, Krupanidhi College of Pharmacy, Bengaluru
2 Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bengaluru
3 Department of Pharmaceutics, NITTE College of Pharmaceutical Sciences, Bengaluru
lithamjthomas85@gmail.com

Effective dentin regeneration requires precise, localized, and sustained delivery of bioactive molecules that can stimulate dental stem cell activity and promote odontoblastic differentiation. Aspirin, a well-established anti-inflammatory agent, has emerged as a promising candidate for dental tissue engineering due to its demonstrated dentinogenic potential when administered via an optimized carrier system. This study aimed to develop and characterize a thermoresponsive in situ gel incorporating aspirin-loaded poly(lactic-co-glycolic acid) (PLGA) microspheres for the site-specific delivery and for regeneration. The optimized PLGA microspheres were prepared by double emulsion solvent extraction method, which was then incorporated into gel by a cold-mixing method using Pluronic F127 and chitosan and optimized. The optimized formulation exhibited a sustained triphasic release profile over 16 days and demonstrated excellent biocompatibility with human dental pulp stem cells (HDPSCs), maintaining 74.61-100% cell viability with minimal cytotoxicity at concentrations of 250 µM and 500 µM. The study demonstrated that the thermosensitive aspirin-loaded PLGA microsphere gel significantly enhanced cellular uptake in HDPSCs, confirmed by fluorescence microscopy and flow cytometry, due to chitosan's mucoadhesive properties and microsphere clustering. Alizarin Red S staining showed increased mineral deposition at 500 µM, indicating improved odontoblast differentiation. Western blotting revealed elevated DSPP expression and Wnt10a co-expression, implicating the Wnt/β-catenin pathway in dentinogenesis. Additionally, FGF-2 expression was markedly increased, supporting osteogenic differentiation and tissue regeneration. These findings confirm the formulation's odontogenic

ISBN: 978-81-980623-8-3

potential and highlight its promise as a minimally invasive strategy for targeted dentin repair via stem cell activation.

**Keywords:** PLGA microspheres; Dental pulp stem cells; Stem cell stimulation; Cell uptake; Remineralization

**RESEARCH IN VARIOUS DOSAGE FORMS FOR THE MANAGEMENT OF NEURODEGENERATIVE DISEASES**

Prof. Amiyakanta Mishra1, Basanta Kumar Behera1, Himansu Ranjan Palatasingh1 Dr. Chinmaya Keshari Sahoo2
1Department of Pharmaceutics, College of Pharmaceutical Sciences (CPS), Puri,Bidyaniketan, Puri-Konark Marine Drive Road, Odisha-752004
2School of Pharmacy, The Neotia University, Jhinga, Sarisa, DH Road, West Bengal, India-743368

Neurodegenerative diseases (NDs) are the disorders due to demolition of neuronal cells by alternation of proteins. The NDs arise due to influence of environment and genetic association of abnormal protein accumulation. It results swelling of cells, further more oxidative stress in the central nervous system (CNS).The management of NDs are allopathic, Ayurveda medications, Unani and Siddha medicines as well as yogic approach. Practicing regularly yoga offers relaxation to mind and calmness to the brain which reduces headache, releases stress, depression and improves blood supply to various organs of the body. Current dosages for treating neurodegenerative illnesses differ greatly according on the ailment, drug type, and mode of administration. The majority of medications only treat symptoms; they don't treat the underlying neurodegeneration. Current studies are also looking into novel strategies, such as creative drug delivery systems that use drug targeting to get across the blood-brain barrier.

**ADVANCES IN NANOCARRIER-BASED OCULAR DRUG DELIVERY SYSTEMS: A FOCUS ON INFLAMMATORY AND INFECTIOUS DISEASES WITH MUCOADHESIVE AND BIODEGRADABLE APPROACHES**

Annu Mehta, D.K. Pradhan, Harish Gupta, Ishwari Choudhary
Raigarh College of Pharmacy, Raigarh C.G. India 496001
annumehta1602@gmail.com

Ocular drug delivery presents unique and formidable challenges due to the complex anatomy and physiology of the eye, which severely limit the bioavailability of therapeutic agents. Conventional ophthalmic formulations, such as eye drops, suffer from rapid pre-corneal clearance, low drug retention, and poor permeation across ocular barriers. This review paper provides a comprehensive overview of the significant advancements in nanocarrier-based ocular drug delivery systems, specifically focusing on their application in inflammatory and infectious eye diseases. We highlight the critical role of mucoadhesive and biodegradable strategies in enhancing drug residence time, improving ocular bioavailability, and enabling targeted delivery. Various nanocarrier platforms, including polymeric nanoparticles, lipidic nanocarriers, micelles, dendrimers, and in-situ gelling systems, are discussed in detail, along with their synthesis, characterization, and mechanisms of action. The review also addresses the current challenges, future prospects, and the potential of these innovative systems to revolutionize the treatment of ocular inflammatory and infectious conditions, ultimately leading to improved patient outcomes and compliance.

**Keywords:** Ocular drug delivery, infectious eye diseases, nanocarrier, Targeted ocular delivery.

**PC-660**

**DEVELOPMENT AND EVALUATION OF CHRONOTHERAPEUTIC DELIVERY SYSTEMS FOR ROSUVASTATIN IN HYPERCHOLESTEROLEMIA MANAGEMENT**

Sneha and M Swetha
Department of Pharm D, Department of Regulatory Affairs, Sarojini Naidu Vanita pharmacy maha Vidyalaya, Affiliated to Osmania University, 500017
snehagoutambhansali@gmail.com

Chronotherapy aligns medication administration with the body's biological rhythms to enhance therapeutic outcomes for various disorders. This study aims to develop and characterize a chronotherapeutic drug delivery system for rosuvastatin, a statin widely used to treat hypercholesterolemia. Since cholesterol synthesis peaks at night, rosuvastatin is well-suited for time-controlled, pulsatile drug formulations that synchronize its release with circadian rhythms. Rosuvastatin chrono formulations were prepared using wet granulation and hydrophilic/hydrophobic polymers. Pre-formulation studies confirmed suitable flow properties, with an angle of repose of 30°54', a bulk density of 0.426±0.08 g/cm³, and a Carr's index of 15.48±0.04, indicating good compressibility. Six granule formulations (F1–F6) with varying hydroxypropyl methylcellulose (HPMC) and ethyl cellulose concentrations were evaluated. In vitro release studies showed controlled patterns: F1 exhibited the highest cumulative drug release (97.45% over 6 hours), while F6 had the slowest (65.42% over 10 hours). Hydrogels for lag-time-controlled release, especially EP4, demonstrated significant swelling (index: 89.35) and a lag time of 2.5 hours, indicating a strong ability to modulate drug release. Capsule robustness was confirmed by minimal changes in size after treatment. Solubility studies in 0.1 N HCl showed gradual dissolution, reaching maximum solubility at 10 hours and maintaining it at 24 hours. Overall, the optimized rosuvastatin chronotherapy formulation achieved controlled drug release and promises improved patient compliance and effective hypercholesterolemia management.

**"REDREVEAL: A PH-RESPONSIVE TOOTHPASTE FOR EARLY IDENTIFICATION AND HEALING OF ORAL ULCER" (WHAT YOUR MOUTH CAN'T SAY)**

Soham Joshi*, Prathamesh Khadake , Damini Karande, Dr. Priya Katiyar , Dr. Kuldeep Vinchurkar
*Sandip Institute of Pharmaceutical Sciences, Mahiravani, Nashik

The present invention relates to a novel, multifunctional toothpaste formulation designed to serve both therapeutic and diagnostic purposes in proactive oral healthcare. This innovative composition is specifically engineered to include a pH-responsive chromatic indicator, enabling real-time visual detection of oral health abnormalities. The chromatic system utilizes natural, phytochemical-based compounds most preferably anthocyanins derived from Clitoria ternatea (commonly known as butterfly pea) which exhibit distinctive and reversible colour changes in response to alterations in the oral pH environment. Such deviations in pH are often early indicators of underlying pre-ulcerative, inflammatory, or pathogenic conditions within the oral cavity. The incorporation of this smart, colour-changing feedback mechanism allows users to visually monitor their oral biochemical status during routine brushing, thereby facilitating early detection and self-assessment. This empowers individuals to seek timely preventive care and mitigates the progression of oral disorders such as aphthous ulcers, mucosal irritation, and microbial infections. Beyond diagnostic capability, the formulation is enriched with a synergistic blend of herbal bio-actives known for their anti-inflammatory, antimicrobial, antioxidant, and mucosal-regenerative properties. These actives contribute to both the immediate alleviation of symptoms and long-term oral tissue protection. The entire composition remains non-invasive, user-friendly, and suitable for daily use without causing any discomfort or side effects. By combining conventional oral hygiene with intelligent health monitoring, the invention transforms tooth brushing into a dynamic, personalized healthcare experience. It holds significant promise for widespread application in both individual and community-level oral health management, particularly in preventive dentistry and consumer-driven health awareness.

**Keywords:** Smart toothpaste pH-responsive indicator Clitoria ternatea Anthocyanins Oral diagnostics

**"TINY DROPLETS, BIG IMPACT: A NOVEL NANOPLATFORM FOR CONSISTENT AND ENHANCED ORAL DELIVERY"**

Mr. Sohal Mallick*, Dr. Preeti Karwa, Dr. Ayesha Syed
Department of pharmaceutics, Al-Ameen College of Pharmacy, Bangalore, Karnataka- 560027

ISBN: 978-81-980623-8-3

Trandolapril, a potent angiotensin-converting enzyme (ACE) inhibitor, is clinically valuable in the management of hypertension and heart failure but is severely constrained by poor aqueous solubility, dissolution-limited absorption, and extensive first-pass metabolism, resulting in a low and variable oral bioavailability of ~4–14%. These barriers undermine therapeutic consistency and necessitate dose escalation, thereby increasing systemic risk. Lipid-based carriers, particularly self-nanoemulsifying drug delivery systems (SNEDDS), provide a transformative strategy to overcome solubility challenges, exploit lymphatic transport, and effectively bypass first-pass metabolism. In this work, a Trandolapril-loaded SNEDDS was systematically designed and statistically optimized to enhance oral delivery. Solubility studies identified oleic acid, Cremophor RH40 and Transcutol P as the most suitable excipients. Pseudo-ternary phase diagrams delineated nanoemulsion domains, and a $3^2$ full factorial design was employed to investigate the influence of oil concentration and Smix ratio on droplet size, polydispersity index (PDI), and emulsification efficiency. The optimized formulation (FS8) generated ultra-fine nano-droplets of 19.43 nm with a narrow PDI (0.251), rapid self-emulsification within 32.6 s, and a high negative zeta potential (-28.42 mV), signifying excellent thermodynamic stability. In-vitro release achieved 87.48% cumulative release within 24 h, significantly surpassing the crystalline drug and following near zero-order kinetics. Atomic Force Microscopy confirmed spherical nanoscale morphology, while robustness to dilution, cloud point analysis, and stability testing demonstrated unwavering integrity under stress conditions. Collectively, these findings establish that the optimized SNEDDS profoundly enhances solubilization, dissolution, and stability of Trandolapril, offering a clinically translatable nanoplatform with the potential to redefine its therapeutic performance in hypertension management.

**Keywords:** Trandolapril, SNEDDS, Factorial design, Solubility enhancement, Hypertension.

## "DESIGN, OPTIMIZATION, AND EVALUATION OF 3D-PRINTED TABLETS CONTAINING ANTIHYPERTENSIVE COMPLEX: A STATISTICAL PERSPECTIVE"

Kuldeep Vinchurkar*1, Dinesh Kumar Mishra2
1Department of Pharmaceutics, Sandip Institute of Pharmaceutical Science, Nashik, (M.H.) – 422213, India
2Department of Pharmacy, Guru Ghasidas Vishwavidyalaya, Koni, Bilaspur (C.G.) –495009, India
kuldeepvinchurkar@gmail.com

The crucial focus of the current study was to design, optimize, and characterize a 3D-printed Nifedipine-Dexolve® complex-loaded tablet (3DPBDCT) using the fused deposition modeling (FDM) technique accomplishing the approach of progressive statistical and analytical tools. Nifedipine (BST) was selected as a prototypical medicine for 3DPBDCT due to its low bioavailability mainly due to poor aqueous solubility, short half-life (5hrs), high dose variation (15-125mg), and intra-subject variability. Initially, the solubility of the BST was improved by complexion with Dexolve®. The complex was prepared and evaluated for its different characterization. Fourier transform infrared (FTIR) and Differential Scanning Calorimeter (DSC) performed to confirm the structural and physical alteration. The complex was loaded into the 3-D printed tablet using the cavity method to form 3DPBDCT. The 3DPBDCT was formulated using FDM technology. The influence of varied shapes on BST release was assessed. A predicted plasma concentration curve was generated using back-calculation of the Wagner-Nelson approach. The compatibility study results indicate physical and chemical compatibility between the BST and chosen excipients. BST:Dexolve® (1:1) improved maximum solubility compared to another ratio and other complexing agents. DSC and FTIR confirmed the alteration of crystalline to amorphous form. The donut shape was chosen for the design of optimized 3DPBDCT due to its controlled release and better post-fabrication results. CCD had found a significant relationship between chosen CPPs and CQAs. The 3DPBDCT gave the desired pre and post fabrication results. The optimal 3DPBDCT can release 98.22% of the BST in 12 hours. The optimal 3DPBDCT was observed to be stable. The FDM technique was able to generate a donut-shaped 3DPBDCT. The effect of % infill and layer thickness significantly influenced the fabrication of 3DPBDCT. Dexolve® was considered a multifunctional excipient, improving stability and solubility. In addition, 3-D printing technology was adopted to give customized dose, design flexible shapes, sizes and modulate BST release to enhance patient compliance. The newly designed 3DPBDCT opens a new direction in the Pharmaceutical field.

**Keywords:** Nifedipine, Dexolve®, 3D Printing, FDM, Cavity method, Customized dosage form

## FORMULATION AND EVALUATION OF MICRONUTRIENT TRANSDERMAL PATCH FOR POTENTIAL NUTRIENTS SUPPLEMENT BY TRANSDERMAL DRUG DELIVERY SYSTEM

Tanmay Jagdale†, Tabbasum K. Sheikh, Dr.Devendra Visokar*
Modern College of Pharmacy, Department of Pharmaceutics, Nigdi, Pune.
tanmayjagdale4@gmail.com

Transdermal drug delivery system (TDSS) is defined as self contained, discrete dosage forms which, when applied to intact skin, deliver the drugs through the skin, at a controlled rate to systemic circulation. This study aims to identify formulations and evaluation of transdermal patch for potential nutrients supplement by transdermal drug delivery system. The transdermal patches was successfully prepared with the hematinic agents Ferrous Ascorbate and Folic Acid also with the use of Hydroxy propyl methyl cellulose, Polyvinyl pyrrolidone and Dimethyl Sulfoxide. Organoleptic studies was carried out for the parameters of the Ferrous Ascorbate and Folic Acid Development of the standard curve of the drug using UV visible spectrophotometer. The transdermal patches were successfully prepared with hematinic agents, Ferrous Ascorbate and Folic Acid. The Pre-formulation study of drug was done using UV Visible spectroscopic method and FTIR.

**Keywords:** TDSS, FTIR, UV visible Spectroscopy, Ferrous Ascorbate.

## FORMULATION AND IN VITRO EVALUATION OF LEVOSULPIRIDE NANOSUSPENSION FOR ANTIAPSYCHOTIC ACTIVITY

G Tejashree1*, R Prasanthi2
Department of Pharmaceutical Quality Assurance, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Hyderabad, Telangana, India – 500017.

Levosulpiride, a BCS Class IV drug, suffers from poor aqueous solubility and low permeability, resulting in limited bioavailability when administered orally. To address these challenges, a nanosuspension of Levosulpiride was formulated using the anti-solvent precipitation method. This technique effectively reduces particle size, thereby enhancing the drug's surface area and dissolution rate. Hydroxypropyl methylcellulose(HPMC E15) and Tween 80 were employed as stabilizers during formulation. The prepared nanosuspension was evaluated for critical in vitro parameters including particle size, polydispersity index (PDI), zeta potential, pH, and cumulative drug release. FTIR studies confirmed no drug-excipient interactions, indicating formulation stability. The optimized batch demonstrated improved drug release and physical stability. Overall, the nanosuspension formulation significantly enhanced the solubility and dissolution profile of Levosulpiride, which may contribute to better bioavailability and therapeutic efficacy in treating antipsychotic condition.

**Keywords:** Anti-solvent precipitation method, nanosuspension, solubility enhancement.

## FORMULATION AND EVALUATION OF GASTRO RETENTIVE IN-SITU GEL OF CIPROFLOXACIN

Ch. Kiranmai, Department of pharmaceutics
Vijaya institute of pharmaceutical sciences for women, Enikepadu, Vijayawada, Andhra Pradesh, India - 521108

The development and evaluation of a gastro-retentive in situ gel containing ciprofloxacin for better drug administration was the primary goal of this investigation. The effects of varying concentrations of calcium carbonate, sodium alginate, and HPMC K-100 on viscosity and drug release at 8 hours were investigated after the in-situ gel was created using a blend of natural and synthetic polymers. A number of parameters, including appearance, pH, viscosity, buoyancy, gelling capacity, swelling index, drug content, and in-vitro drug release, were assessed for the produced formulation. The in-situ gel exhibited a sustained drug release profile along with desirable physicochemical

ISBN: 978-81-980623-8-3

characteristics. Every formulation exhibited the ideal viscosity to facilitate swallowing and administration. All formulations floated for more than 12 hours, with floating lag times ranging from 43 to 75 seconds. The in vitro gelling capacity increased as the calcium carbonate and sodium alginate concentrations increased. With a high swelling index, formulation F6 demonstrated the gel's capacity to absorb a significant volume of liquids. Moderate, prolonged, and reliant on the sodium alginate and HPMC K-100 concentrations were the in vitro drug release characteristics of these in-situ gels. In vitro drug release was sustained (67.23%) for 12 hours in formulation F6, which contained 1.25% sodium alginate and 2% HPMC K-100. Using first order kinetics, the drug was released from formulation F6. The gastro retentive in situ gel of F6 is a potentially effective drug delivery method for enhancing ciprofloxacin's bioavailability and therapeutic effectiveness. Overall, the study showed that in situ gel-based drug delivery systems could be used to enhance ciprofloxacin's efficacy.

**Keywords:** Gastrointestinal retentive, Ciprofloxacin, in situ gel, floating time, and in vitro drug release.

**FORMULATION AND IN VITRO EVALUATION OF DOXOFYLLINE CHITOSAN MICROSPHERES BY EMULSION CROSS-LINKING METHOD USING SURFACE RESPONSE METHODOLOGY**

Poosa Harini1*, R Prasanthi2
Department of Pharmaceutical Quality Assurance, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Hyderabad, Telangana, India – 500017.
harinipoosa@gmail.com

The creation and in vitro assessment of doxofylline-loaded chitosan microspheres are the main objectives of this work, employing the emulsion cross-linking method in conjunction with surface response methodology (SRM). The aim was to optimize the microsphere characteristics to enhance drug delivery efficacy. Chitosan, chosen for its biocompatibility and biodegradability, was utilized to encapsulate doxofylline, a bronchodilator used in the treatment of respiratory diseases. The emulsion cross-linking technique facilitated the formation of microspheres, while SRM was applied to chitosan concentration, cross-linking agent concentration, and emulsification speed on the microsphere properties. The encapsulation effectiveness, shape, particle size determination, and in vitro drug release profile of the resultant microspheres were assessed. The optimised formulation showed a regulated release pattern of doxofylline, a good encapsulation effectiveness, and a desired particle size. These results imply that chitosan microspheres prepared using this technique may be a viable means of boosting the distribution of doxofylline, thereby augmenting both patient compliance and the medication's therapeutic efficacy in the treatment of respiratory diseases.

**Keywords:** Doxofylline, Emulsion Cross-linking, Surface response methodology (SRM), encapuslaiotion efficiency, In vitro drug release, Controlled release, Respiratory diseases, Bronchodilator.

**FORMULATION DEVELOPMENT AND OPTIMIZATION OF YOHIMBINE HYDROCHLORIDE LOADED PLGA NANOCARRIERS**

K. Divya and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
divyakrr2023@gmail.com

Yohimbine possesses considerable therapeutic potential, functioning as an anti-inflammatory, anticancer, and fat-burning agent. However, its clinical application is restricted by pharmacokinetic challenges such as poor solubility, low oral bioavailability, and extensive hepatic first-pass metabolism, which collectively reduce its therapeutic effectiveness. To address these limitations, the present study focuses on developing yohimbine-loaded PLGA nanoparticles (YBN-PLGA) aimed at enhancing drug release, improving oral bioavailability, and increasing anti-fibrotic efficacy. YBN-loaded PLGA nanoparticles were prepared using a double emulsification and solvent evaporation method. The formulation was optimized by systematically assessing key formulation and process variables. Characterization of the optimized nanoparticles was carried out using Fourier Transform Infrared Spectroscopy (FTIR), Differential Scanning Calorimetry (DSC), and Powder X-ray Diffraction (p-XRD). The optimized formulation exhibited a particle size of 210 nm, a PDI of 0.01, a zeta potential of –34 mV, and an entrapment efficiency of 64%. Importantly, the YBN-PLGA nanoparticles displayed a sustained drug-release profile compared to pure yohimbine hydrochloride when tested under simulated gastrointestinal and physiological conditions. These findings suggest that the optimized nanoparticle formulation, with its suitable particle size for oral delivery, may improve yohimbine's bioavailability and enhance its therapeutic potential for managing fibrotic disorders.

**Keywords:** Polymeric nanoparticles, Yohimbine, Sustained release, PLGA.

**PC-669**

**FORMULATION, DEVELOPMENT AND EVALUATION OF AGMATINE SULFATE NANOCARRIER FOR MUSCLE REGENERATION**

Radhika R. Tambi, Amol A. Tatode, Milind J. Umekar
Smt. Kishoritai Bhoyar College Of Pharmacy New Kamptee, Nagpur, Maharashtra, India
radhikatambi21@gmail.com

Volumetric muscle loss [VML] is defined as the traumatic or surgical loss of skeletal muscle with resultant functional impairment. In response, a variety of tissue engineering and regenerative medicine treatments for VML injury are under preclinical development. To regenerate the loss of muscle and muscle function are critical feature in treatment of muscle injury. The purpose of this research was to formulate agmatine loaded gelatine and collagen nanocarrier [AGM-Gelatine-Collagen]. Gelatine protein rich substance and collagen help in cell adhesion used to target muscle loss. 3^2 factorial design was used to investigate the influence of formulation variables, quantity of Gelatine [X1], and [X2] on the formation of hydrogel to attain the required characteristics. Drug [Agmatine], Gelatine and Collagen were added to Propylene glycol and hydrogel were synthesized using the heating/cooling a polymer solution method. The optimized batch was assessed for its physical appearance, pH, viscosity, drug content, in vitro release, ex vivo study, stability and in vivo studies. The optimized formulation showed a viscosity of 228 cP and % drug release 50.6%, sustained release behaviour was observed in 12hrs. Stability of the formulation shows no significant changes after 45days of storage. In vivo studies suggest that there is regeneration of muscle Fibers and negligible collagen deposition occurs when the hydrogel is fixed to the injured muscle after 15 days' time period. Therefore, it was concluded that the formulation could be very promising alternative for the muscle regeneration treatment.

**Keywords:** Volumetric Muscle Loss [VML], Gelatine-Collagen Hydrogel, Agmatine,Muscle regeneration

**PC-670**

**FORMULATION DEVELOPMENT AND IN-VITRO EVALUATION OF MINOXIDIL-BEARING GLYCEROSOMES FOR ANDROGENIC ALOPECIA**

Sahana S, Asha S, Dr. Rama Bukka, Dr. Shachindra L. Nargund
M. pharm, Pharmaceutics, Nargund College of Pharmacy, Bangalore-560085

This study explored vesicular drug delivery systems to improve dermal drug delivery. Glycerosomes, vesicles enriched with glycerol, enhance skin penetration by modifying vesicular composition, increasing drug entrapment, and sustaining release. Minoxidil-loaded glycerosomes were developed as an advanced topical formulation for the treatment of androgenetic alopecia, aiming to enhance follicular delivery, promote regeneration, and improve therapeutic efficacy compared with conventional formulations. Absorption through hair follicles bypasses the stratum corneum, the skin's main barrier, providing a direct route into the dermis and its dense capillary network. The follicular route is particularly valuable for targeted delivery in conditions such as hair loss, where it enhances local therapeutic outcomes. Glycerosomes were prepared using the lipid thin-film hydration method with soya lecithin, cholesterol, and glycerol (20%, 30%, and 40%). Optimization was performed using Design Expert 13 with a $3^2$ factorial design, yielding nine formulations characterized for particle size, zeta potential, entrapment efficiency, and in vitro release. The optimized formulation (F1) showed spherical vesicles without aggregation, particle size of 120.63 and sustained release for up to 13 hours, following zero-order kinetics with a non-Fickian diffusion mechanism. FTIR confirmed drug–excipient compatibility, and drug estimation showed linearity at λmax 288 nm.

ISBN: 978-81-980623-8-3

Among the tested formulations, 40% glycerol-based glycerosomes demonstrated superior performance and were incorporated into HPMC K100M gel, which showed suitable pH, viscosity, appearance, and enhanced release. Overall, glycerosomes provide a promising drug delivery platform with improved therapeutic potential for managing androgenetic alopecia.

**Keywords:** Glycerosomes, Minoxidil, Hair follicle absorption, HPMC K100M gel, In vitro release

**FORMULATION AND IN VITRO EVALUATION OF DEXLANSOPRAZOLE ORAL FILMS**

Nomitha Medha Byreddy and R. Prasanthi
Department of PharmD, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya,
Tarnaka, Secunderabad, Telangana, India-500017.
nmbyreddy@gmail.com

The aim of this study was to prepare dexlansoprazole oral films using solvent casting method. For the preparation of dexlansoprazole oral films, a total of 4 oral films were prepared F1, F2, F3 and F4. The formulated oral films were evaluated for folding endurance, weight variation, thickness, pH, disintegration, in vitro dissolution test, and drug-excipient compatibility by Fourier Transform Infrared Spectroscopy (FTIR). In this study, polyethylene glycol 400 (PEG 400) was used as a plasticizer, HPMC E15 as a polymer, sodium saccharin as an artificial sweetener, and ethanol as the solvent. Among the 4 formulated oral films, the F3 formulation containing: 30mg of dexlansoprazole, 250 mg of HPMC E15, 80 mg of sodium saccharin, 0.3 ml of PEG 400, and 7.5 ml of ethanol, was found to be the most effective one. The evaluation parameters for F3 formulation were as follows: weight variation of 413.7 ± 2.5 mg, thickness of 0.19 ± 0.07 mm, pH of 6.8 ± 0.8, folding endurance of 51 ± 3, disintegration of 26 ± 2 seconds, and in vitro % drug release of 96.32 ± 0.78 %. Given the drug release profile was highest in the F3 formulation with 96.32%, this formulation was concluded as the optimized formula. In conclusion, dexlansoprazole oral films were successfully prepared by thin solvent casting method.

**Keywords:** dexlansoprazole, oral thin films, solvent casting method, drug release, invitro evaluation.

**FORMULATION AND EVALUATION OF PERSONALIZED ORODISPERSIBLE FILMS FOR PEDIATRIC EPILEPSY**

Sonkar Shubhangi Shrikant,
Mula Education Society's college of Pharmacy, Sonai, Tal- Newasa, Dist-Ahilyanagar Affiliated to Savitribai Phule Pune University, Pune.
shubhangisonkar2004@gmail.com

Personalized orodispersible films (ODFs) are a promising dosage form for pediatric epilepsy treatment, offering benefits like improved patient compliance, faster onset of action, and enhanced bioavailability. These films disintegrate rapidly in the mouth, eliminating the need for water, which is particularly useful for children with epilepsy who may have difficulty swallowing tablets or capsules. ODFs can be tailored to meet individual patient needs, allowing for precise dosing adjustments. The buccal route of administration avoids first-pass metabolism, potentially increasing the effectiveness of medications like pregabalin. ODFs are a more palatable option for pediatric patients, reducing the risk of choking and aspiration associated with traditional solid dosage forms. Studies have explored various technologies for preparing ODFs, including vacuum compression molding (VCM) and hot-melt extrusion (HME). These methods offer advantages like solvent-free processing and the ability to create customized dosage forms. Researchers have successfully developed ODFs with APIs like diclofenac sodium and pregabalin, demonstrating promising results in terms of disintegration time, mechanical properties, and drug release profiles. Personalized ODFs can be designed to deliver anti-seizure medications like pregabalin, improving treatment outcomes and patient compliance. ODFs are a valuable option for pediatric patients, addressing the need for age-appropriate formulations that are easy to administer and minimize dosing errors.

**Keywords:** Personalized orodispersible films; anti-seizure medications

**PC-673**

**FORMULATION AND IN VITRO EVALUATION OF LIPOSOMES FOR CO-DELIVERY OF DOCETAXEL AND CURCUMIN TO TREAT TRIPLE NEGATIVE BREAST CANCER**

Sagar G., Barnabas Wilson
Department of Pharmaceutics, College of Pharmaceutical Sciences, Dayananda Sagar University, Devarakaggalahalli, Harohalli, Kanakapura Road, Bengaluru -562112

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype lacking conventional therapeutic targets (ER, PR, HER2) and is often associated with multidrug resistance (MDR) to chemotherapy. Curcumin (CUR), a natural polyphenol with anticancer and chemosensitizing properties, and docetaxel (DTX), a first-line chemotherapeutic, were co-encapsulated in liposomes to enhance in vitro therapeutic efficacy against TNBC. Aim of the study: To develop and optimize liposomal formulation for co-deliver of docetaxol and curcumin. Experimental: Liposomes containing docetaxol and curcumin (CUR-DTX-L) was prepared by thin film hydration using egg lecithin, cholesterol, and stearylamine as lipid components. A three-factor Box-Behnken design optimized the lipid composition for maximal drug entrapment and stable formulation. The liposomes were characterized for mean vesicle size (nanoscale), zeta potential, entrapment efficiency (EE), and in vitro drug release in phosphate-buffered saline (pH 7.4). Results & Discussion: The optimized co-loaded formulation showed very high entrapment efficiencies: 99.2% for CUR-DTX-L, 98.32% for CUR-L (curcumin-only), and 89.2% for DTX-L (docetaxel-only). CUR-L liposomes (formulation FC8) released 87.95% of curcumin over 24 hours at pH 7.4. Release kinetics fit the Korsmeyer-Peppas model, indicating a Super Case II transport mechanism. The Box-Behnken optimization yielded robust model fits ($R^2 > 0.98$ for entrapment and release responses), confirming the reliability of predictions. The optimized liposomes were nanosized with a slight positive surface charge (from stearylamine), indicating good colloidal stability. Conclusion: Docetaxel and curcumin were successfully co-formulated into a single liposomal system with near-complete drug encapsulation and sustained release characteristics. The in vitro findings demonstrate a promising strategy for combination drug delivery in TNBC, warranting further investigation.

**Keywords:** Triple-negative breast cancer; liposomes; curcumin; docetaxel; dual drug delivery

**FORMULATION AND EVALUATION OF MUCOADHESIVE BUCCAL FILMS OF ACYCLOVIR**

Ms. Renita Jyothi Monis Mrs. Yuvashree R, Mr. Sudarshan D J
Institute of Health Management Research, Bangalore
renitamonis28@gmail.com

Acyclovir is an effective antiviral drug. The currently available conventional therapy of Acyclovir is associated with several drawbacks, including highly variable absorption, low bioavailability after oral administration, and a short plasma half-life. Hence, the present work aims to formulate mucoadhesive buccal films of acyclovir to enhance therapeutic efficacy, patient compliance, and bioavailability by bypassing first-pass metabolism. In the present study, two formulations of mucoadhesive drug delivery of acyclovir were prepared as buccal films using the solvent casting method. Pullulan and Chitosan were used as mucoadhesive polymers, and HPMC K4M as the film-forming agent. The prepared films were evaluated for their thickness, surface pH, drug content uniformity, folding endurance, tack test, and in vitro release. The FTIR spectra of acyclovir revealed no interaction between the drug and the polymer during the formulation process. Drug content of the films ranged from 82.10-96.11%, indicating uniform distribution of acyclovir. Among the two formulations, F1(HPMC+pullulan) showed superior folding endurance, drug content uniformity, mucoadhesion, and sustained drug release (84.5% in 6h) compared to F2 (HPMC+chitosan). Overall, the study demonstrated that mucoadhesive buccal films of acyclovir are a promising mucosal drug delivery system for improving therapeutic efficacy and Patient compliance.

**Keywords:** Acyclovir, Pullulan, Chitosan, Solvent Casting technique, Mucoadhesive Buccal Films.

**PC-675**

**FORMULATION AND EVALUATION OF ASPIRIN-LOADED THERMO-RESPONSIVE GEL FOR ANTI-INFLAMMATORY ACTIVITY**

ISBN: 978-81-980623-8-3

Harish Rajaraman
Department of pharmaceutics, Pallavan pharmacy college,
Kanchipuram, India-631502

In the research, an aspirin-loaded thermo-responsive gel was formulated. The primary objective of the study is to investigate the localized effect of aspirin formulated as a thermo-responsive gel administered topically. The formulated of thermos-responsive aspirin gel three batches drug compatibility, diffusibility, pH, gelation temperature, gelation strength and viscosity, BSA method for anti-inflammatory activity were evaluated and results are found that thermos-responsive gel as pH ranges 6.4-6.8, gelation strength and viscosity is ideal balance in formulation two with appropriate concentration of polymer poloxmer (18%), gelation temperature at the body temperature ranges 32-37℃.UV revealed an absorbance peak at 236nm, which identified the drug used.IR analysis showed that there is no interaction between the drug and polymer used in the formulation. The partition coefficient measured 1.36 ± 0.039, showing moderate lipophilicity appropriate for diffusion across biological membranes. The BSA method for the anti-inflammatory activity of F2 and F3 shows better activity than the standard drug diclofenac. Therefore, the aspirin-loaded thermo-responsive gel was formulated using the BSA method. Thus, it is concluded that it is beneficial to formulate aspirin as a thermos-responsive gel for anti-inflammatory activity.

**Keywords:** Aspirin, in-situ gel, thermos-responsive gel, BSA method

## SUBLINGUAL LOZENGE FORMULATION COMPRISING WITHAFERIN ENRICHED WITHANIA SOMNIFERA LEAF EXTRACT FOR COGNITIVE AND NEUROPROTECTIVE APPLICATION

Sakshi Balaji Pachbhai*
Dr. Meghraj Suryavanshi, Dr. Kuldeep Vinchurkar, Dr. Lakshmikant Borse
*Sandip Institute of Pharmaceutical Sciences

Cognitive impairment and neurodegenerative disorders pose a major global health burden, often linked with oxidative damage, neuroinflammation, and progressive decline in neuronal integrity. Withania somnifera (Ashwagandha), a cornerstone of Ayurvedic medicine, is well recognized for its adaptogenic, neuroprotective, and cognitive-enhancing effects. Among its phytoconstituents, Withaferin A has emerged as a potent bioactive compound with demonstrated neuroprotective activity. In this work, a novel sublingual lozenge formulation was designed incorporating Withaferin A–enriched Withania somnifera leaf extract. The sublingual route was chosen to enable rapid absorption, bypass hepatic first-pass metabolism, and enhance systemic bioavailability, thereby offering faster therapeutic onset. The lozenge matrix was optimized for taste, stability, and controlled drug release, ensuring patient compliance and acceptability. This innovative formulation offers a promising nutraceutical and therapeutic intervention, with potential applications in improving memory, cognitive performance, and supporting long-term neuroprotection in individuals at risk of neurodegenerative conditions.

**Keywords:** Withania somnifera, Withaferin A, sublingual lozenge, cognitive enhancement, neuroprotection, herbal formulation, bioavailability.

## DEVELOPMENT OF NOVEL CO-PROCESSED EXCIPIENT AS A DIRECTLY COMPRESSIBLE VEHICLE

Vanitha Kond, Vaidehi, Ramesh Alluri
Department of Pharmaceutics, Vishnu Institute of Pharmaceutical Sciences, Vishnupur, Narsapur, India, Telangana - 502313

Oral disintegrating tablets (ODTs) improve patient compliance, especially in pediatric, geriatric, and dysphagic populations. Enalapril Maleate, an angiotensin-converting enzyme (ACE) inhibitor with poor water solubility, was selected as a model drug to evaluate the efficiency of synthetic and natural superdisintegrants in ODT formulations. ODTs of Enalapril Maleate were prepared by direct compression using synthetic superdisintegrants (Croscarmellose Sodium, Sodium Starch Glycolate) and a natural disintegrant (Plantago ovata mucilage). Eight formulations were developed and evaluated for pre-compression and post-compression parameters, in vitro disintegration, dissolution, drug content uniformity studies. All formulations complied with pharmacopoeial specifications. Among synthetic batches, CCS3 exhibited the shortest wetting time (8.55 s), disintegration time (17.64 s), and rapid dissolution (99.24% at 20 min). The natural formulation PO2 (20 mg Plantago ovata mucilage) showed comparable performance with disintegration time of ~12–14 s and nearly complete drug release (99.98% at 20 min). Both natural and synthetic superdisintegrants effectively produced ODTs of Enalapril Maleate with rapid disintegration and dissolution. Plantago ovata mucilage demonstrated comparable efficiency to synthetic disintegrants, supporting its potential as a cost-effective, sustainable, and eco-friendly alternative for ODT formulations.

**Keywords:** Oral disintegrating tablets, Enalapril Maleate, Superdisintegrants, Plantago ovata mucilage, Direct compression, Dissolution

## SCREENING POLYMERS FOR DEVELOPMENT OF ELECTROSPUN NANOFIBRES FOR SOLUBILITY ENHANCEMENT OF POORLY SOLUBLE DRUG

*Girija A. Ghatge1, Ashok A. Hajare,2 Kiran Sharma3
1. *Ph.D. Research Scholar, Bharati Vidyapeeth College of Pharmacy, Kolhapur
2. Professor, Department of Pharmaceutics, Bharati Vidyapeeth College of Pharmacy, Kolhapur
3. I/C Director & Professor, School of Nanoscience Technology, Kolhapur

Currently, about 40% or more of drugs in development and about 60% of molecules obtained directly from synthesis are poorly soluble in water. The solubility behavior of poorly water-soluble drugs remains one of the most challenging aspects of formulation development. Electrospun nanofibers have unique properties such as they have high surface area to volume ratio, inter/inner porosity and uniform morphology. Electrospun nanofibers have an undoubted advantage over other drug delivery vehicles due to their cheap fabrication cost and ease of scalability. In present study; different polymers likes Eudragit® L 100-55, Eudragit® E PO, Parteck® SLC, Aeroperl® 300 were screened for successful development of Electrospun Nanofibres for Solubility Enhancement of Poorly Soluble Drug. Initially placebo Electrospun nanofibers were developed and characterized for morphology (FESEM), surface area, contact angle, etc were determined. Sertraline which is BCS Class II drug and used as anti-depressent was selected as a model drug to entrap in to electrospun nanofibres. Different batches of Sertraline loaded electrospun nanofibres were prepared using Eudragit® L 100-55 in combination with Parteck® SLC and Aeroperl® 300. Developed nanofibres were evaluated for % yield, drug content, encapsulation efficiency, solubility, etc. Nonofibres equivalent to 50 mg of Sertraline were mixed with lactose as diluents and evaluated for pre-compression parameters. Tablet of Sertraline loaded electrospun nanofibres were prepared and evaluated for post compression parameters and in-vitro dissolution study. Results showed that, enhancement of solubility of Sertraline in electrospun nanofibres as compared to plain drug. Also cumulative % drug release was tremendously enhanced. Study concluded that, Eudragit® L 100-55 in combination with Parteck® SLC and Aeroperl® 300 are suitable polymers for successful development of Electrospun nanofibers for enhancement of solubility and dissolution of poorly water soluble drug like Sertraline.

## PHARMACODYNAMIC EVALUATION OF ASH-ZINC OXIDE NANOPARTICLES: SYNERGISTIC GEL FORMULATION FOR WOUND HEALING AND ANTI-INFLAMMATORY APPLICATIONS

Aishwarya Jain1,2, Kiran Bhise1
Department of Pharmaceutics, Allana College of Pharmacy, K.B. Hidayatullah Road, Azam Campus, Pune, Maharashtra, India
Department of Pharmaceutics, Shri Vile Parle Kelvani Mandal's College of Pharmacy, Shirpur
ash.starred@gmail.com/doctoraishwaryajain@gmail.com

This study aims to develop and evaluate the wound-healing and anti-inflammatory potential of Ash-ZnO NPs and Ash-ZnO NPs gel formulation, synthesised using Saraca asoca extract and stabilised in a chitosan matrix. The goal was to overcome the limitations of conventional ZnO nanoparticles, including instability, cytotoxicity, and uncontrolled release. Although ZnO nanoparticles possess antimicrobial and regenerative properties, their clinical utility is limited by aggregation and dose-dependent toxicity. The use of Saraca asoca, a medicinal plant rich in flavonoids and phenolics, provides a green synthesis approach that enhances nanoparticle stability and biological activity. Incorporation into a chitosan-based gel further improves topical application by enhancing adhesion, moisture retention, and sustained release. Chitosan also contributes additional healing benefits due to its intrinsic biocompatibility, antimicrobial activity, and role in tissue regeneration. Ash-ZnO NPs were synthesised through a green co-precipitation method and formulated into a chitosan hydrogel. In vitro assays, including MTT, scratch wound, and protein denaturation tests, were used to assess cytocompatibility, fibroblast migration, and anti-inflammatory potential. In vivo wound-healing efficacy was evaluated in rats using an excision model, supported by histopathological analysis. The Ash-ZnO NPs gel exhibited 72.5% inhibition of protein denaturation and achieved 75.63% wound closure within 48 h. Histology confirmed organised tissue architecture and minimal inflammation. The Ash-ZnO NPs gel represents a promising, biocompatible wound-care formulation that enhances nanoparticle stability, modulates inflammation, and accelerates tissue repair, offering strong potential for clinical dermatological applications.

## AN INVESTIGATION ON DEVELOPING BUCCAL TABLETS CONTAINING CO-CRYSTALLIZED SELEXIPAG

Samikcha Rai1, Preethi Sudheer2, Nimisha Jain1, Dennith D3*
1Krupanidhi College of Pharmacy, Bangalore, Bangalore, Karnataka, India
2,3. Nitte College of Pharmaceutical Sciences, Bangalore, Karnataka,

Selexipag is a selective prostacyclin receptor agonist for treating pulmonary arterial hypertension. Selexipag is a Biopharmaceutics Classification System ( BCS II) drug with 49% oral bioavailability and 2h half-life. This study focuses on enhancing solubility using co-crystallization and incorporating crystals into buccal tablets for improved drug effectiveness. Drug co-crystals were prepared using acetamide as coformer via slow solvent evaporation. The co-crystal was converted into buccal tablets of hydroxypropyl methyl cellulose (HPMC), Carbopol and Xanthan gum. The tablets were evaluated for physical parameters, drug content, swelling index, in vitro release, and ex vivo profiles. A 14-fold increase in solubility a % CDR of co-crystals were found to be 28.8± 0.3 to 62.56± 0.8 % at 120 min compared to 19.71± 0.059% from pure drug. X-ray diffraction pattern suggested a change in drug crystalline nature. The buccal tablets exhibited good tableting properties. Drug release from eight-tablet formulation ranged between 84.3±0.23 % and 94.34%. Force of adhesion of selected tablet (F8) on goat buccal mucosa was 3.38 N, with 89.15±0.21 % drug permeated at 8 h compared to 24.21±0.23 % from pure drug. This study demonstrates cocrystals' usefulness in solubility enhancement, release profiles, and buccal tablet formulations.

## IN-VITRO CHARACTERIZATION AND SYNTHESIS OF BISDEMETHOXYCURCUMIN NANOPARTICLES FOR THE TREATMENT OF CANCER

Lilima Baghel, Chanchal Deep Kaur
Rungta College of Pharmaceutical Science and Research, Managed by Krishna Vikash Institute, Near Nandanvan – 492099, Raipur, Chhattisgarh, India

The extraction and modification of naturally-occurring compounds are widely performed due to their valuable medicinal and physical properties. Herin, we reported the extraction of bis-demethoxycurcumin from Ragbrai turmeric root. The isolated derivative was characterized by X-ray diffraction, IR, and NMR spectroscopy. Also, the green synthesis of bis-demethoxycurcumin chitosan silver BDMC-Ag-Ch nanoparticles is illustrated. These nanoparticles are identified by atomic force microscopy AFM and exhibit average particle size - 53.41 nm The crystalline structure was confirmed by XRD analysis, which showed distinct peaks corresponding to silver oxide nanoparticles and Zeta power measurements revealed stable dispersion of the nanoparticles, indicating a good chitosan coating on the surface of bisdemethoxycurcumin Ag nanoparticles. The absorption bands at 240 and 405 nm are due to oxygen atom ($n \rightarrow \pi^*$) and aromatic ($\pi \rightarrow \pi^*$) transitions in curcumin and Chitosan molecules. The photoluminescence (PL) study of synthesized BDMC-Ag-Ch nanoparticles demonstrated an existence of two emission excited states in light-emitting, namely local excited and intramolecular charge transfer emission states, due to the aromatic conjugation system within BDMC units and intra charge transfer between the silver ion and organic part.

## DESIGN AND DEVELOPMENT OF MICROEMULSION-BASED FORMULATION OF NIFEDIPINE TO IMPROVE BIOAVAILABILITY BY COMPLEXATION METHOD

Kuljeet Kaur1, Popin Kumar2, Viney Chawla1
University Institute of Pharmaceutical Sciences and Research, Baba Farid University of Health Sciences, Faridkot, Punjab, India, 151203
Gyani Inder Singh Institute of Professional Studies, Dehradun, Uttarakhand Technical University, Dehradun, India

In the current research, a microemulsion-based formulation of Nifedipine was prepared. The objective was to improve the solubility and bioavailability using complexation method. These factors are critical to the effectiveness of the oral medications. The formulation was prepared using sesame oil, Tween 80 (Surfactant), and Polyethylene glycol 400 (Cosurfactant). These agents work synergistically to stabilize the microemulsion and improve the drug dissolution rate in the stomach. To improve the activity of the developed formulation, β-cyclodextrin was added as a complexing agent. This complexing agent can form a host-guest inclusion complex with the drug, effectively enhancing its solubility. The combination of the oil, surfactant, and cosurfactant was varied in 4:4:2, which ensured a perfect balance among components. The developed microemulsion-based formulations were evaluated for dispersibility index, percentage transmittance, droplet size, and in vitro drug release. The results of optimized formulation F14 revealed that the

ISBN: 978-81-980623-8-3

stable formulations had a percentage transmittance of >90%, indicating clarity was associated with stability. The particle size was measured to be in the nano range, with a polydispersibility index of 0.221. The zeta potential value of the developed formulation was found to be 64.1, indicating good stability. The dispersibility was assessed using a dissolution apparatus, and the developed formulations were classified as Grade A, as they rapidly form a bluish transparent emulsion within 1 minute. The results of cumulative percentage drug release showed that 80% of the drug release occurred in 20 minutes. This rapid release shows significant enhancement of drug absorption for developing an effective formulation of nifedipine. Overall, the results highlight the potential of microemulsions to improve the solubility and bioavailability of poorly soluble drugs.

**Keywords:** SMEDDS, microemulsion, complexation, β-cyclodextrin, Nifedipine

**FORMULATION AND IN VITRO EVALUATION OF NANOEMULSION CONTAINING TENELIGLIPTIN**

Jincy Thomas1, Kannoth Mukundan Geetha1 and Barnabas Wilson2
1 Department of Pharmacology, College of Pharmaceutical Sciences, Dayananda Sagar University, Harohalli, Kanakapura Road, Bengaluru - 562112, India
2 Department of Pharmaceutics, College of Pharmaceutical Sciences, Dayananda Sagar University, Harohalli, Kanakapura Road, Bengaluru - 562112, India
jincypharmacology@gmail.com

The current study aims to formulate Teneligliptin, a novel dipeptidyl peptidase-4 (DPP-4) inhibitor, that is emergingly used in the management of type 2 diabetes mellitus and Alzheimer's disease. Despite its clinical advantages, the medication's inconsistent oral absorption and poor water solubility may lower the therapeutic efficacy. A promising approach to overcoming these obstacles is provided by nanoemulsion-based drug delivery systems, which improve solubility and bioavailability while permitting prolonged release. Their potential as an effective nanomedicine is great, since they can readily solubilize hydrophobic medications, reduce severe side effects, and be easily transformed into next-generation nanomedicine. High-speed homogenization was used to prepare the nanoemulsion containing Teneligliptin. The prepared nanoemulsions were characterized for globule size, drug content, zeta potential and in vitro release studies. Studies on In vitro release showed a quick initial release of the medication followed by a prolonged release, indicating better solubility and long-term sustained availability. The particle size analysis study showed that the mean particle size was 7.847 nm and the zeta potential was -24.1 mV. The TEM study showed that the particles were spherical in shape. The in vitro drug release studies showed that the nanoemulsion were able to sustain the drug release for 24 h.

**Keywords:** Nanoemulsion, Teneligliptin, Diabetes, Homogenization, Drug delivery.

**DEVELOPMENT AND ASSESSMENT OF A FLOATING IN-SITU GEL FOR GASTRORETENTIVE DELIVERY OF METFORMIN HCL**

Polimetla Lohitha Sri and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
polimetlalohithasri@gmail.com

The objective of this study was to formulate and evaluate a gastro retentive in situ gel of Metformin HCl for enhancing its bioavailability, prolonging gastric residence time, reducing dosing frequency, and improving patient compliance. The in-situ gel was formulated using a combination of natural and synthetic polymers, and effects of different concentration of sodium alginate, HPMC K-100 and calcium carbonate on viscosity and drug release at 8 hrs were studied. The prepared formulation was evaluated for various parameter like appearance, pH, viscosity, buoyancy, gelling capacity, swelling index, drug content and in-vitro drug release. All the formulations showed an optimum viscosity that will allow ease of administration and swallowing. Floating lag time of all formulations was between 43- 75 seconds and floated for >12 h. The in vitro gelling capacity increased with increasing concentration of the sodium alginate and calcium carbonate. The formulation F6 showed high swelling index, which indicates that gel is capable of absorbing a large amount of fluid. In vitro drug release form these insitu gels were slow, extended and dependent on the concentration of sodium alginate and HPMC K-100 used. The formulation F6 containing 1.25% sodium alginate and 2% HPMC K-100 showed sustained in vitro drug release (67.23 %) over an extended period of 12 h. Overall, the study demonstrated the potential of in situ gel-based drug delivery systems for improving the performance of Metformin HCl.

**Keywords:** Gastro retentive, In situ gel, Floating time, In-vitro drug release and Metformin HCl

**PC-686**

**DEVELOPMENT OF NOVEL TOPICAL DELIVERY SYSTEM FOR DERMATOLOGICAL TREATMENT**

Sakthi Uma R P, Tejas R, Bharath Srinivas
Department of Pharmaceutics, Faculty of Pharmacy,
M.S. Ramaiah University of Applied Sciences, Bengaluru, Karnataka, India – 560 054
sakthirp2253@gmail.com

Skin diseases like acne, corn, callus and wart are seen to be more prevalent in present and future. The prevalence of skin disorders is increasing globally and rising market expansion for keratolytic agents is anticipated to increase. Salicylic acid is used as first line of drug for treatment of skin disorders. Due to its poor aqueous solubility and highly skin irritant at higher concentrations in the formulation, the scope of salicylic acid as dermatological preparation is challenging. The present research was envisaged for the development of topical delivery system of salicylic acid with increased aqueous solubility and acceptable drug release over a period. Solubility enhancement of salicylic acid was attempted with various techniques and finally by co solvency using PEG-400 and Propylene glycol (3:1), the solubility of drug could be enhanced up to 26%. Various strategies were adopted for dermatological preparations and finally gel formulation using Carbopol - 940 was found to be most compatible. The pharmaco-technical evaluation studies indicated simulated skin pH values, thixotropic viscosity and drug content within the standard limits as per the monograph. DLS of salicylic acid gel formulation indicated drug particle size to be as 283nm. The in-vitro and ex-vivo drug permeation studies of final formulation showed a drug release of 97% and 95% at the end of 4 hours. The acute dermal irritation test on rabbit model revealed that the gel formulation to be non-irritant and accelerated stability studies conducted as per ICH guidelines confirmed stability of the formulation during shelf life assessment.

**Keywords**: Topical delivery, solubility enhancement, salicylic acid, skin disorder

**PC-687**

**RECENT ADVANCEMENT AND FUTURE PERSPECTIVES OF POLYMERIC NANOPARTICLES IN THE TREATMENT OF COLORECTAL CANCER DRUG DELIVERY SYSTEM**

Ravi Sharma,1,2 Gajanan Darwekhar,2 Elangovan Manivannan*1
1School of Pharmacy, Devi Ahilya Vishwavidyalaya, Indore-452001 (M.P.)
2Acropolis Institute of Pharmaceutical Education and Research, Indore-453771 (M.P.)

As per the WHO report colorectal cancer (CRC) caused around 8,81,984 deaths worldwide in 2022. Colorectal cancer is the third most prevalent cancer in the world by incidence and the second most common cancer in terms of death. Currently existing anti-colorectal cancer therapies, including radiation, and anticancer therapeutics etc., have limited therapeutic efficacy, side effects, and low success rates. So, there is a need for a better anti-cancer therapy with minimal side effects and maximum success rate. In recent years, the application of the nanotechnology in developing anti-cancer therapeutics has gained much attention due to its drug delivery ability, improve the treatment efficiency, overcoming drug resistance and reducing side effects. Nanoparticles are capable of enhancing the intracellular penetration of the drugs into the cancerous cells due to its nanometer size, without affecting the normal cells. Polymeric nanoparticles (NPs) have sparked widespread interest in recent years due to their unique features coming from their small size. Polymeric NPs have several advantages as drug

ISBN: 978-81-980623-8-3

carriers, including the capacity to control release, protect drug and other biologically active compounds from the environment, and improve bioavailability and therapeutic index. Among this Chitosan-based nanoparticles (ChNPs) have shown promising potential as nanocarriers in colorectal rectal cancer drug delivery and therapeutics. ChNPs can encapsulate anticancer medications and deliver them to cancer cells in the body, giving controlled release. Herein, we discuss some examples of potential application of ChNPs in colorectal cancer drug delivery.

**Keywords:** Colorectal cancer, nanoparticle, polymer, chitosan, drug delivery

**NOVEL MEDICATED PEN DELIVERY SYSTEM A PATIENT-FRIENDLY APPROACH FOR TOPICAL MANAGEMENT FOR ANTI ACNE ACTIVITY.**

Alina Bi Shaikh, Maheen Ismail Mulla, Suraj Kumbhar, Yogendra Salunke, Dr. Jaya Agnihotri.
Department of Pharmaceutical Sciences, H.K College of Pharmacy, Mumbai University, Maharashtra, Mumbai-400102.

Significant advancements in drug delivery focus on enhancing patient compliance, safety, and efficacy. Conventional topical formulations such as ointments, creams, and gels, though widely used, are often inconvenient, greasy, and less portable, leading to poor adherence. Novel delivery systems aim to overcome these limitations by improving convenience and reducing dosing frequency. Medicated pens with advantages like portability, precision, hygiene, and uniform application, are emerging as suitable alternatives for dermatological conditions such as acne vulgaris. Pre-formulation studies were conducted on selected active ingredients and excipients. Manjistha extract (deep brown, water-soluble liquid), Niacinamide (amorphous white, water-soluble powder), and Sandalwood oil (pale yellow, oil-soluble liquid) were evaluated as APIs. Excipients included Sodium Lauryl Sulphate, Ceto-stearyl alcohol, Almond oil, Carnauba wax, Beeswax, PEG 400, Glycerine, and Petroleum jelly. FTIR analysis of Manjistha confirmed characteristic peaks at 3323.35 $cm^{-1}$ (aliphatic alkyl), 2970.38 and 2885.51 $cm^{-1}$ (–OH), and aromatic absorptions, indicating rubaidin-related structures. Topical medicated pens containing manjistha–niacinamide and manjistha–sandalwood oil combinations were successfully formulated using standard pharmaceutical techniques. Both preparations demonstrated uniformity, safety, and therapeutic effectiveness in acne management. The developed medicated pens offer a novel, patient-friendly, and effective approach for the topical management of acne vulgaris. Their portability, precision, and hygienic application enhance patient compliance, highlighting their potential as promising anti-acne therapies.

**Keywords:** Acne vulgaris, Manjistha, Niacinamide, Sandalwood oil, Medicated pen, Topical drug delivery.

**NOVEL ORO MUCOSAL SPRAY FOR ANTIANGINAL THERAPY**

Yogendra Salunke, Suraj Kumbhar, Maheen Ismail Mulla, Alina Bi Shaikh, Dr.Jaya Agnihotri.
Department Of Pharmaceutics,H.K College of Pharmacy, Mumbai University, Mumbai, India-400102

A selective If current inhibitor, used in the management of chronic stable angina and heart failure, shows limitations in conventional oral dosage forms such as first-pass metabolism, delayed onset, and swallowing difficulties in elderly or paediatric patients. To overcome these challenges, an Oro mucosal spray formulation was developed as a promising alternative, offering rapid absorption, improved compliance, and avoidance of hepatic metabolism.Solid dispersions of the antianginal agent were prepared by solvent evaporation using a rotary evaporator (drug: polymer ratio 1:3-1:4). The dried amorphous powder was incorporated into a spray system and characterized by DSC, PXRD, and FTIR to confirm amorphization and compatibility. The spray delivered uniform doses (~0.95-1.05 mg/actuation, RSD <5%), maintained stable pH (6.2-6.4), and exhibited acceptable spray ability. In-vitro solubility and ex-vivo permeation studies showed enhanced dissolution and a 2-3-fold increase in mucosal absorption compared to plain solution.This novel Oro mucosal spray demonstrates potential for rapid angina. relief and improved therapeutic performance, warranting further pharmacokinetic and clinical evaluation.

**Keywords:** Oro mucosal spray, Antianginal therapy, If current inhibitor, Solid dispersion, Mucosal permeation

**PC-690**

**NOVEL DUAL FILM-FORMING GEL THERAPY FOR VITILIGO**

Suraj Kumbhar, Maheen Ismail Mulla, Yogendra Salunke, and Alina Bi Shaikh, Dr.Jaya Agnihotri.
Department of Pharmaceutical Sciences, H.K College of Pharmacy, Mumbai University, Maharashtra, Mumbai-400102.
kumbhar.suraj9833@gmail.com

Vitiligo is a chronic skin disorder characterized by loss of natural pigment, leading to visible white patches that affect confidence and quality of life. The present research investigates a dual-drug film-forming gel combining a BCS Class II immunosuppressant and a BCS Class IV vitamin D analogue to enhance therapeutic efficacy while minimizing side effects. Conventional topical formulations such as ointments and creams are greasy, poorly retained, and cosmetically less acceptable, whereas film-forming gels provide a transparent, quick-drying, and patient-friendly alternative. The synergistic combination of BCS Class II and IV drugs plays a crucial role: the Class II drug suppresses autoimmune activity that damages melanocytes, while the Class IV analogue stimulates melanocyte activation and promotes repigmentation. Together, they complement each other's mechanisms, addressing both immune regulation and pigment restoration for superior outcomes compared with monotherapy. The formulation was developed using solubility-enhancing co-solvent systems to improve drug availability. Upon drying, volatile components evaporated, creating a supersaturated state that enhanced skin permeation. Incorporation of suitable polymers further prevented recrystallization and stabilized the formulation. The optimized gel showed a skin-compatible pH (5.4), 93% drug content, smooth spreading, and rapid drying within 1–2 minutes. It provided sustained release and significantly higher skin retention than the occulusive marketed ointment. These findings suggest that a synergistic dual-drug film-forming gel of BCS Class II and IV drugs represents a novel, cosmetically elegant, and patient-friendly treatment strategy for vitiligo.

**Keywords:** Vitiligo, Film-forming gel, BCS Class II, BCS Class IV, Synergistic therapy, Repigmentation, Solubility enhancement.

**RECENT DEVELOPMENTS AND APPROACHES IN THE DESIGN OF NANOSTRUCTURED LIPID CARRIERS AND THEIR UTILIZATION FOR BRAIN TARGETING.**

Rabina Kalita and Mukta Agrawal
Royal School of Pharmacy, The Assam Royal Global University, Guwahati, Assam
rabinakalita08@gmail.com

Lipid-based nanocarriers have become a promising tool for targeted drug delivery over the past two decades. They are widely explored for delivering drugs to challenging sites such as the central nervous system (CNS), tumours , and the cardiovascular system. Their major advantages include biocompatibility, flexibility in design, and the ability to carry a wide range of therapeutic agents. Among lipid carriers such as nano emulsions, liposomes, and solid lipid nanoparticles (SLN), nanostructured lipid carriers (NLCs) stand out as the most advanced system. NLCs offer high stability, large drug-loading capacity, efficient encapsulation, and controlled drug release. These properties make them particularly suitable for brain-targeted therapy, where drug delivery is limited by the blood–brain barrier (BBB). The nano-size, lipid matrix, and surface modifications of NLCs allow them to cross the BBB more effectively compared to conventional systems. They are also scalable for industrial production, safe, non-irritant, and compatible with diverse drugs. This review summarizes the progress in developing NLCs for brain drug delivery. It highlights their pharmacokinetics, formulation strategies, and therapeutic role in neurological diseases such as Alzheimer's, Parkinson's, epilepsy, schizophrenia, multiple sclerosis, brain cancer, cerebral ischemia, CNS infections, and cerebral malaria. Two key approaches are emphasized: drug delivery across the BBB and direct intranasal (nose-to-brain) administration. Both strategies show promise in improving treatment outcomes for CNS disorders. Overall, NLCs represent a versatile and effective platform for overcoming current challenges in brain-targeted drug delivery, with strong potential for clinical translation.

**3D PRINTING OF PERSONALIZED DOSAGE FORMS: ADVANCING PATIENT-CENTRIC AND PRECISION MEDICINE**

Deepali P. Kale*, Dr. Dipti B. Ruikar

Three-dimensional (3D) printing is emerging as a transformative technology in pharmaceutical manufacturing, enabling the development of personalized dosage forms tailored to individual patient needs. Unlike conventional batch production, 3D printing allows precise control over dose strength, geometry, drug release kinetics, and the incorporation of multiple active ingredients into a single unit. This flexibility is particularly valuable for pediatric and geriatric populations, where fixed-dose limitations, swallowing difficulties, and high pill burden compromise adherence. Advances in printable biocompatible materials and the integration of artificial intelligence (AI)-based predictive modeling further enhance formulation optimization and reproducibility. The approval of the first 3D-printed drug, Spritam®, underscores regulatory recognition of this technology, though challenges remain in scaling production, quality assurance, and standardization. Importantly, the potential for decentralized, point-of-care manufacturing offers revolutionary applications in emergency care, orphan drugs, and personalized therapy. In conclusion, 3D printing represents a crucial step toward patient-centric and precision medicine, offering customizable, on-demand treatments that improve therapeutic outcomes and compliance.

**MARKETED COW URINE DISTILLATE: MASKING THE TASTE AND ODOR FOR BETTER PATIENT COMPLIANCE**

Sujata Khobragade, Damodar Gouaple
Department of Pharmaceutics, Anurag College of Pharmacy Warthi, Bhandara -441905
sujatapolymath@gmail.com

In Indian culture, the cow holds a unique place of reverence, and cow urine has long been valued in traditional medicine for its therapeutic potential. Historical references trace its use back to Vedic times, where it was believed to support health by restoring physiological balance. Owing to its natural origin, eco-friendly nature, affordability, and safety, cow urine and its distillate continue to be explored as potential therapeutic agents. Despite its benefits, the strong taste and odour often limit patient compliance. The present study focused on enhancing palatability by incorporating natural sweeteners such as honey and essential oils like citronella oil, with the aid of suitable adsorbents. Comparative analysis of the original and modified formulations using FTIR spectroscopy confirmed that the addition of these agents significantly improved taste and odour without altering the chemical integrity of the active constituents. The improved formulation offers a more acceptable and patient-friendly version of Panchgavya medicine, supporting its wider therapeutic application.

**Keywords:** Cow urine, Panchgavya medicine, FTIR, taste masking, odour masking, palatability.

**DESIGN AND OPTIMIZATION OF A BIOCOMPATIBLE PATCH INCORPORATING ENDOCRINE DRUG-LOADED VESICULAR SYSTEM FOR TARGETED BREAST CANCER THERAPY.**

Chanchal Badhai, Manju Rawat Singh, Deependra Singh
University Institute of Pharmacy, Pt. Ravishankar Shukla University, Raipur, Chhattisgarh, India – 492010.

In this study, a vesicular drug delivery system (VDDS) encapsulating an endocrine drug was developed and incorporated into a bioactive-loaded biocompatible patch for breast cancer management. This approach addresses limitations of conventional endocrine therapies, including poor solubility, systemic toxicity, and lack of site-specific targeting. The bioactive was incorporated into the patch to provide additional therapeutic benefits and synergistic activity, enhancing the overall efficacy of the delivery system. Formulation parameters were systematically evaluated for particle size, zeta potential, drug entrapment, loading capacity, and in vitro release. The optimized vesicular system was engineered for selective delivery to breast cancer tissue while maintaining physicochemical and structural stability. Morphological analysis using SEM and TEM confirmed uniform nanoscale vesicles, and FTIR demonstrated drug–exipient compatibility, indicating the absence of chemical interactions. The biocompatible patch was assessed for thickness, moisture content, tensile strength, and drug release kinetics, confirming its suitability for transdermal application. The results show that integrating the VDDS into the bioactive-loaded patch enhances localized drug delivery, improves targeting, and maintains structural integrity, demonstrating its effectiveness as a delivery platform. This minimally invasive system provides a stable, efficient, and site-specific approach that reduces systemic effects compared to conventional methods, highlighting its potential for advanced breast cancer therapy.

**Keywords:** Breast cancer, vesicular drug delivery system, biocompatible patch, endocrine drugs, targeted therapy.

**PC-695**

**EFFECTS OF NATURAL PERMEATION ENHANCER ON DEVELOPMENT OF OXAPROZIN TRANSDERMAL PATCH USING QUALITY BY DESIGN APPROACH**

Sakshi Satish Patil, Sushmitha N, Sangeetha G
Department of Quality Assurance, Krupanidhi College of Pharmacy, Bangalore, Karnataka, India.

In the present study transdermal patch of Oxaprozin, a NSAIDs drug were developed using Quality by Design principles to overcome the problems of oral administration such as hypotoxicity, poor absorption, gastric irritation and extensive first pass metabolism. Oxaprozin transdermal patch were formulated by the solvent evaporation method employing Eudragit RS 100 as polymer and optimized using Custom Design to evaluate the effect of different natural skin permeation enhancer. The experimental design recommended 13 runs involving 2 factors Eudragit RS 100 and natural skin permeation enhancer (Rosemary oil, oleic acid, limonene) and 3 responses in-vitro drug release, thickness and folding endurance. Each of the 13 formulation were prepared and evaluated. The optimized transdermal patch was characterized for moisture content, thickness, weight variation, drug content, in vitro drug release, ex vivo permeation and skin irritation study. The predicted global desirability of the optimized oxaprozin transdermal patch was found to be 0.87891. The patch in vitro and ex vivo permeation studies for the patch was found to be 82.94% and 74.26% respectively for 7 hours. Draize irritancy test was performed and confirmed no signs of skin irritation. Thus, it was concluded that oxaprozin transdermal patch was safe and effective alternative to oral therapy by reducing gastrointestinal irritation, bypasses first pass metabolism thereby improves the management of chronic inflammatory disorders.

**Keywords:** Oxaprozin, Natural permeation enhancer, Quality by Design, Custom design.

**TAILORED THERAPEUTICS: THE ROLE OF 3D PRINTING IN PERSONALIZED MEDICINE**

Pranshu Aggarwal, Pooja Chawla and Viney Chawla
University Institute of Pharmaceutical Sciences and Research, Faridkot, Punjab, India – 151203
aggarwalpranshu91@gmail.com

The convergence of three-dimensional (3D) printing and biomedicine has ushered in transformative possibilities for personalized medicine, enabling customised therapeutic solutions precisely matched to individual patient anatomies and biology. This poster examines recent advances in 3D bioprinting, additive manufacturing of biomaterials, and patient-specific implants and drug delivery systems. Key technical developments—including bioink formulation, multi-material and hybrid fabrication, and high-resolution volumetric printing—are evaluated for their ability to enhance cell viability, vascularization, and functional integration in engineered tissues. Applications across various biomedical domains are highlighted: tissue engineering (organs, skin, cartilage), regenerative medicine, personalized orthopaedics (patient-specific bone scaffolds and implants), and customised drug delivery (tailored dosage forms and release kinetics). For example, a multiphasic scaffold incorporating platelet-rich plasma into alginate-gelatin bioinks showed

ISBN: 978-81-980623-8-3

improved chondrogenesis of bone marrow mesenchymal stem cells (BM-MSCs), and strong interfacial mechanical properties between cartilage and bone regions. Despite these advances, certain challenges like: achieving robust vascularization and innervation in larger constructs; standardization of materials and bioinks; ensuring reproducibility and regulatory compliance; scalability and affordability need to be addressed. The poster concludes with perspectives on overcoming these barriers via integrated multi-disciplinary efforts, advanced imaging and modelling tools and innovative fabrication strategies. Overall, 3D printing holds strong promise to make personalized medical care more feasible, safe, and effective.

**Keywords:** 3D bioprinting, vascularization, personalized medicine, bioink formulation

**FORMULATION AND EVALUATION OF ATORVASTATIN CALCIUM LIQUISOLID TABLETS & COMPARING THE DISSOLUTION DATA WITH MARKETED TABLET**

Bathula Swetha and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
swethabathula1804@gmail.com

The objective of the present investigation was to improve dissolution and bioavailability of a practically insoluble Hypercholesterolemia drug Atorvastatin calcium using liquisolid technique. Liquisolid compacts was prepared by using Span – 80 as a non-volatile solvent, Microcrystalline cellulose, lactose, Dicalcium phosphate, Hydroxy propyl methyl cellulose as carrier materials and Collodial silica as a coating material in different ratio. The prepared liquisolid compacts were evaluated for micromeritic properties & drug –excipient interactions by FTIR. The liquisolid tablets were prepared and evaluated for their tableting properties. The interaction between drug and excipients was characterized by FT-IR studies, which showed that there is no interaction between drug and excipients. The results of pre and post compression parameters were comply with pharmacopoeial limits. In vitro drug dissolution study was carried by using USP dissolution apparatus II & pH 6.8 phosphate buffer for 45minutes; its results comply with IP limits for tablets. The dissolution study of an optimized formulation (F8) compared with marketed tablets and it was found that F8 showed significant higher drug release rate than marketed tablet. From the study, it was concluded that the liquisolid technique is an effective approach to enhance the dissolution rate of Atorvastatin calcium.

**Keywords:** Atorvastatin calcium, Liquisolid technique, Dissolution rate.

**PC-698**

**ADVANCES IN NIOSOMAL CARRIERS FOR ENHANCED TOPICAL DRUG DELIVERY: A CASE STUDY WITH CHLORPHENIRAMINE NIOSOMAL GEL**

Harsha Sahu*, Research Scholar
Rungta College of Pharmaceutical Science and Research, (RCPSR) R1, Bhilai. C.G.

Niosomes are a novel drug delivery system, in which the medication is encapsulated in a vesicle. The vesicle is composed of a bilayer of non-ionic surface-active agents and hence the name niosomes. Topically applied niosomes can increase the residence time of the drug in the subcutaneous and epidermis while reducing the systemic absorption of drugs. Thus, niosomes act as penetration enhancers. Niosomal gel plays a key role for penetration of the drugs across skin. The topical drug delivery of niosomal gel is very useful in the treatment of skin allergic reaction. Niosomal gel can be applied by topical route, since they have prolonged retention and enhanced penetration and that will automatically improve therapeutic properties. Niosomal gels are more convenient over conventional oral drugs. Because in oral formulations there are certain limitations such as limited targeting ability, short retention time in gastrointestinal tract, and low bioavailability. And also, oral administration requires repeated administration of drug. It has very poor solubility in acidic pH of the stomach and hence remains in stomach walls for a long period, aggravating its potential side effect like peptic ulcer and gastric irritation. Novel drug delivery System, like niosomes, extend the drug's shelf life and efficacy by shielding it from environmental influences and enzymatic destruction. By using different concentration of polymers, the formulation and evaluation of chlorpheniramine niosomes has been prepared by using ether injection method. A14 gauge needle was selected for preparation of formulation. Pre-formulation analysis uses FTIR to ensures the drug purity and its compatibility with excipients. The gel, however, exhibit some instability in accelerated conditions (40°C), suggesting that higher temperatures may have an impact on the formulation's long-term stability. The chlorpheniramine niosomal gel's pH was found to be approximately 5.9, which is within acceptable range for topical application. The maximum cumulative drug release (93.25%) in 8 hours and hence it is the best formulation.

**NANO CRYSTALS OVERCOMING MULTI-DRUG RESISTANCE (MDR) IN CANCER THERAPY**

Aman Dubey, Dr. S.S. Burle, Milind Umekar, Mr. R.T. Lohiya
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur

Multi-drug resistance (MDR) poses a major obstacle in modern cancer therapy, as it drastically reduces the effectiveness of conventional treatment approaches and often contributes to disease relapse as well as unfavorable clinical outcomes. One of the central mechanisms driving MDR is the excessive activity of ATP-binding cassette (ABC) transporters, particularly efflux pumps, which actively expel therapeutic agents from the interior of cancer cells. This results in significantly lower intracellular drug concentrations, preventing the achievement of the desired therapeutic effect. In addition to transporter-mediated efflux, several other biological factors contribute to the development of resistance. Given these multifaceted resistance mechanisms, there is an urgent need for innovative strategies to restore or enhance the effectiveness of therapy. Among the emerging solutions, nanocrystal-based systems have attracted considerable attention. Nanocrystals, composed of pure solid drug particles reduced to the nanometer scale, offer unique physicochemical and pharmacokinetic advantages. By improving solubility, dissolution rate, and bioavailability, they can achieve higher intracellular accumulation of therapeutic molecules. Moreover, nanocrystals may bypass efflux transporters and facilitate sustained drug release, thereby improving cytotoxic effects against resistant cancer cells. Consequently, nanocrystal technology holds significant promise as a novel and efficient platform to overcome the persistent challenge of MDR in oncology.

**BRAIN-TARGETED INTRANASAL NANOCARRIERS: A NOVEL APPROACH FOR ALZHEIMER'S THERAPY**

Shrutika S. Nimkar, Dipti Bonde, Tejaswini Masne, Dipti B. Ruikar.
P. R. Pote Patil College of Pharmacy, Amravati, Maharashtra 444604

The nano formulation of Biochanin A intranasal delivery promising new approach for AD treatment. AD is neurodegenerative brain disorder that affect the memory, thinking ability, and also persons ability to perform routine daily activities. The drug delivery to the brain is very difficult because of the presence of BBB. Amyloid beta(β) accumulation, abnormal position of neuritis plaque and neurofibril tangles, cholinergic disfunction, neuroinflammation and oxidative stress burden along with mitochondrial dysfunction are the pathophysiology of AD. The nano formulation are introduced through nose to brain and it gained attention because it give the direct pathways to the brain, this method reduce the side effect in body and avoid the liver first pass metabolism. Biochanin A has already been proven that have neuroprotective effect by decreasing deposition, reducing apoptosis and preventing the production of TNF-α, IL-1β and NO. Biochanin A is a natural compound, occurring from isoflavone group.it is isolated from plant of the glycine(max). It has antioxidant, anti inflammatory and brain protective properties. For the AD treatment it is very useful to treat people. But it has low water solubility and bioavailability and get metabolized quickly. The nano formulation can improve the solubility of Biochanin A, allow slow controlled release, sustain release to the brain targeting. Intranasal delivery of Biochanin A nano formulation can provide direct brain delivery by passing the BBB.

**ROSUVASTATIN: DEVELOPMENT OF AN IMMEDIATE-RELEASE TABLET VIA QUALITY BY DESIGN (QBD) APPROACH**

Aiyushi Das, Dr. Rama Bukka, Dr. Shachindra L. Nargund, Dr. Malviya Nidhi
M. pharm, Pharmaceutics, Nargund College of Pharmacy, Bangalore-560085
dasaiyushi4@gmail.com

In this current research, 40 mg immediate-release rosuvastatin tablet was developed to overcome its low solubility. The approach used Quality by Design (QbD) principles and modern technologies to enhance therapeutic efficacy. To address solubility issues, a nanocrystal suspension of rosuvastatin was prepared. This suspension was then formulated into tablets using a wet granulation process. The formulation incorporated lactose as a diluent and a synergistic blend of croscarmellose sodium and crospovidone as super disintegrants, ensuring rapid tablet disintegration. Magnesium stearate and talc were used as a lubricant and glidant, respectively. The QbD framework included risk assessment, identification of critical material attributes (CMAs), and critical process parameters (CPPs). A Central Composite Design (CCD) was used to define the design space, with disintegrant and binder concentrations as key variables. The results showed that a stable and advanced immediate-release tablet formulation of rosuvastatin was successfully developed using a Quality by Design (QbD) approach. By employing nanocrystal technology and synergistic super disintegrants, the study effectively overcame the drug's low aqueous solubility. The formulated tablets demonstrated superior physical properties, including excellent hardness and very low friability, and achieved a rapid disintegration time of under one minute. In vitro dissolution studies confirmed a substantial increase in drug release, with over 85% of the drug dissolving within the first 15 minutes.

**Keywords:** Rosuvastatin, Nanocrystals, Quality by Design, Immediate-release, Super disintegrants

**SURFACE MODIFICATION OF DRUG NANOCRYSTALS: STRATEGIES AND THERAPEUTIC APPLICATIONS IN SITE-SPECIFIC DELIVERY**

Ishan, Pooja Chawla, Viney Chawla
University Institute of Pharmaceutical Sciences and Research, Faridkot, Punjab, India – 151203
ishandabgotra2001@gmail.com

Nanotechnology includes different strategies involving polymeric nanoparticles, liposomes, lipid nanoparticles, nanocrystals, nanoemulsions, etc., aiming to overcome several limitations of traditional therapeutic approaches. Drug nanocrystals are nanometer-sized drug particles that are considered better than other matrix nanoparticles in terms of their high drug loading and lower toxicity of drug formulation. In addition, nanocrystals significantly improve the solubility and dissolution rate of poorly water-soluble drugs, leading to enhanced oral bioavailability and faster onset of action. Their small particle size (10-500 nm) also provides a larger surface area, which facilitates rapid absorption and reduces variability in drug plasma concentration. They can also be administered through multiple routes, including oral, parenteral, pulmonary, and ocular, thereby offering formulation flexibility. Three methods, i.e., the top-down method, the bottom-up method, and the combination method are generally used for their preparation. Surface modifications with suitable ligands not only enhance physical and chemical stability but also enable targeted drug delivery to specific organs or cells. Folic acid for cancer cells, triphenylphosphonium for mitochondria, etc., are some of the ligands being used. This poster focuses on drug nanocrystals, methods of preparation, surface modification, surface ligand design strategies, and different applications in targeted drug delivery. The future perspectives of this dosage form have also been discussed.

**Keywords:** Drug nanocrystals, Surface engineering, Targeted drug delivery, Ligand modification

**"IONOTROPIC GELATION-BASED MICROENCAPSULATION OF DUAL PLANT OILS FOR ADVANCED FACE CREAM FORMULATION AND CONTROLLED SKIN DELIVERY"**

S.Nivetha
Department of Pharmaceutics, pallavan pharmacy college,kolivakkam, Kanchipuram.
nivethasundar2004@gmail.com

The combination of sweet almond oil (Prunus Amygdalus Dulcis) and rosehip oil (Rosa Canina) provides synergistic skin benefits, including moisturization, anti-aging, and skin regeneration. However, their direct use in topical formulations is limited by issues of stability, volatility, and lack of controlled release. This study explores the development of microsphere-encapsulated sweet almond and rosehip oils using the ionotropic gelation technique to overcome these challenges and enhance the therapeutic efficacy in a face cream formulation. Sodium alginate was employed as the encapsulating polymer, while calcium chloride served as the crosslinking agent to induce gelation and form stable hydrogel microspheres. The oils were emulsified within the polymeric solution and then dropped into the calcium chloride bath to generate oil-loaded spherical microspheres with controlled size and morphology. These microspheres exhibited high encapsulation efficiency and demonstrated sustained in vitro release profiles. Upon incorporation into an oil-in-water cream base, the formulation maintained desirable physicochemical properties, including viscosity, spreadability, and pH suitable for dermal application. The ionotropic gelation method efficiently encapsulates combination oils within biocompatible polymers, improving stability, protecting bioactive compounds, and enabling controlled delivery. This innovative approach holds promise for natural oil-based cosmetic applications by enhancing product performance, stability, and consumer acceptability while harnessing the benefits of plant-derived oils in a single, microencapsulated delivery system. The formulation was evaluated for particle size, entrapment efficiency, pH, viscosity, spreadability, and stability. These results demonstrated that the microsphere-loaded cream exhibited smooth texture, stable pH, good spreadability, and no phase separation, making it a promising formulation for skin care applications.

**Keywords:** sweet almond oil, rosehip oil, microsphere, oil-in-water cream base, ionotropic gelation method.

**SIMVASTATIN LIPOSOMAL GEL: DEVELOPMENT AND CHARACTERIZATION USING THIN FILM HYDRATION METHOD**

Thandra Sarayu and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
thandrasarayu@gmail.com

The skin protects the body against harmful substances and microorganisms. When the skin is damaged, wound healing must be finely regulated to restore the normal function of skin tissue. The current work aims to develop a topical liposomal gel loaded with simvastatin for improved local action to heal the bacterial wounds. The desired simvastatin loaded liposomal gel was formulated by employing a thin-film hydration technique using cholesterol, soya lecithin, and carbopol 940. The formulated liposomal gels were characterized by FTIR, drug loading, entrapment efficiency, surface morphology, particle size, zeta potential, pH, and viscosity. Further, evaluated for in vitro drug release, ex vivo permeation, and stability profile. The optimized liposome F4 suggested that particles were spherical and near homogeneous with relatively smoother surfaces with a particle size of 211nm. The optimized formulation F4 had shown a drug loading of 24.38% and an entrapment efficiency of 79.82%. Further, the optimized liposomal gel G1 had shown enhanced permeation (90.16% in 12h) and displayed sustained release when compared with plain gel (73.78% to 78.23% over 12h). Stability studies suggested that formulated liposomal gel was highly stable at 4-8°C. In conclusion, the formulated simvastatin loaded liposomal gel can be used as a potential therapeutic alternative for healing bacterial wounds.

**Keywords:** Simvastatin; Wound healing; Liposomal gel; Thin film hydration technique; Sustained drug delivery; Permeation

**FORMULATION AND EVALUATION OF ATORVASTATIN CALCIUM LIQUISOLID TABLETS & COMPARING THE DISSOLUTION DATA WITH MARKETED TABLET**

ISBN: 978-81-980623-8-3

Bathula Swetha and Sadhu Venkateswara Rao
Department of Pharmaceutics,, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
swethabathula1804@gmail.com

The objective of the present investigation was to improve dissolution and bioavailability of a practically insoluble Hypercholesterolemia drug Atorvastatin calcium using liquisolid technique. Liquisolid compacts was prepared by using Span – 80 as a non-volatile solvent, Microcrystalline cellulose, lactose, Dicalcium phosphate, Hydroxy propyl methyl cellulose as carrier materials and Collodial silica as a coating material in different ratio. The prepared liquisolid compacts were evaluated for micromeritic properties & drug –excipient interactions by FTIR. The liquisolid tablets were prepared and evaluated for their tableting properties. The interaction between drug and excipients was characterized by FT-IR studies, which showed that there is no interaction between drug and excipients. The results of pre and post compression parameters were comply with pharmacopoeial limits. In vitro drug dissolution study was carried by using USP dissolution apparatus II & pH 6.8 phosphate buffer for 45minutes; its results comply with IP limits for tablets. The dissolution study of an optimized formulation (F8) compared with marketed tablets and it was found that F8 showed significant higher drug release rate than marketed tablet. From the study, it was concluded that the liquisolid technique is an effective approach to enhance the dissolution rate of Atorvastatin calcium.

**Keywords:** Atorvastatin calcium, Liquisolid technique, Dissolution rate.

## EXPLORING POLYMER VARIANTS FOR THE DEVELOPMENT OF FAST DISSOLVING MONTELUKAST FILMS

Vutukuri Mokshitha Sameera and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
mokshithasameera77@gmail.com

The study aimed to develop and evaluate fast-dissolving oral films (FDOFs) of Montelukast sodium to enhance disintegration, dissolution, and bioavailability, thereby improving patient compliance. Films were formulated using HPMC K-15, Guar Gum, and Xanthan Gum as film-forming agents, along with SSG as a super disintegrant and PEG-400 as a plasticizer, via the solvent casting method. There were six formulations (F1–F6), with F4–F6 containing polymer combinations. The films were evaluated for thickness, weight uniformity, moisture uptake, drug content uniformity, folding durability, in vitro disintegration time, and dissolution studies. Results showed that polymer combinations exhibited superior performance over single-polymer formulations, with F6 (HPMC K-15 + Guar Gum + Xanthan Gum) demonstrating the fastest disintegration time (30 ± 0.02 sec) and highest drug release (98.3% within 15 minutes). The films were thin, flexible, and easy to administer, providing a patient-friendly alternative to conventional tablets and capsules for allergic conditions. The study successfully achieved its objectives by formulating FDOFs that enhanced drug dissolution and absorption, providing a convenient and effective alternative to traditional solid dosage forms, particularly benefiting patients with swallowing difficulties.

**Keywords**: Guar gum, Xanthan gum, HPMC K-15, Montelukast sodium, Fast dissolving oral films (FDOFs), Super disintegrants, and Solvent Casting Technique

**PC-707**

## METHOXY POLY (ETHYLENE GLYCOL)-POLY (LACTIDE) (MPEG-PLA) NANOPARTICLES AS NEW CARRIERS FOR DELIVERY OF A PROSTATE CANCER DRUG FLUTAMIDE

Manimukkula Vedhamatha Siva Parvathi and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
mvmsivaparvathii@gmail.com

Methoxy poly(ethylene glycol)-poly(lactide) copolymer (MPEG-PLA) was used to prepared nanoparticles by the 23 factorial design and nanoprecipitation method for clinical administration of a prostate cancer drug Flutamide. The effects of various formulation components such as polymer, organic phase volume and surfactant on the characteristics of nanoparticles were evaluated. The size and size distribution, surface morphology and surface charge of the Flutamide loaded nanoparticles were then investigated by laser light scattering, scanning electronic spectroscopy and zetapotential analyzer. FT-IR studies may indicate interaction between the drug and polymer. The prepared nanoparticles had spherical shape with size less than 100 nm. Zeta potential measurement demonstrated the presence of PEG layer on the particle surface. The drug encapsulation efficiency (EE) and in vitro release profile were measured by UV-Spectroscopy. In-vitro release of drug showed sustained release behaviour for a period of 24 hr. The results of accelerated stability study of optimized formulation F2 revealed that storage conditions were not found to have made any significant changes in formulation. Such a nanoparticle formulation of Flutamide can be expected to have long-circulating effects in systemic circulation. Finally the present investigation opens new frontiers in developing Flutamide NPs for targeting delivery to the prostate for the prostate cancer treatment.

**Keywords**: Nanoparticles, Targeted delivery, Zeta potential and Prostate cancer.

## ARTHRELIEF – ERGONOMICALLY DESIGNED MULTI-LAYER THERAPEUTIC WEARABLE FOR PAIN RELIEF AND REHABILITATION

Maithili Hadge, Mayur Kale, Sandip Rahangdale, Manish Aglawe, Nitu Wankhede, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee

Arthrelief is a therapeutic device designed specifically to relieve the pain of patients suffering from arthritis and similar conditions. Arthritis is a condition in which inflammation of synovial joints occurs, leading to severe symptoms like pain, stiffness, and swelling. It is an alternative and complementary approach offered beyond traditional therapeutic practices. Arthrelief gloves focus on providing comfort and a drug-free solution, reducing the need for frequent clinical visits. Arthritis, encompassing both osteoarthritis and rheumatoid arthritis, is a debilitating condition affecting over 350 million people globally, leading to chronic pain, stiffness, and reduced mobility. Post-stroke rehabilitation, essential for the millions of survivors who suffer from long-term motor impairments, is another critical area of concern, with an estimated 15 million people experiencing a stroke each year worldwide. Arthrelief provides a non-invasive, drug-free solution that can be used in the comfort of one's home, minimizing dependency on clinical facilities. The massage function improves blood circulation, reduces swelling, and alleviates pain, while the heat therapy relaxes muscles, enhances joint flexibility, and accelerates tissue healing. The Arthrelief gloves are engineered with four distinct layers: a silicon layer embedded with flexible spikes for targeted massage, a coil layer acting as a heating agent, a pump with an airbag for dynamic pressure application, and an insulating fabric layer to retain warmth and ensure comfort. This unique combination enables simultaneous massage and heat therapy, offering significant relief from pain and stiffness while aiding post-stroke rehabilitation. From a design innovation perspective, Arthrelief departs from existing therapeutic gloves by integrating multi-therapy functionality into a single, lightweight, and portable wearable. Its layered architecture is not only functional but also ergonomically contoured to fit naturally over joints, ensuring consistent contact for uniform heat and massage distribution. The concealed micro-pump and coil arrangement are embedded without creating bulk, preserving flexibility and hand dexterity. Ventilation micro-channels within the insulating layer prevent overheating while maintaining therapeutic warmth, and the modular design allows easy adaptation to different body parts without redesigning the core technology. This combination of therapeutic efficacy, ergonomic comfort, and aesthetic simplicity makes Arthrelief a novel, patient-friendly, and highly adaptable solution for chronic pain and rehabilitation.

**Keywords**: Arthritis, painrelief, silicon, spikes, heat, massage

## DEVELOPMENT AND IN VITRO EVALUATION OF CAPTOPRIL LOADED FLOATING MICROSPHERES BY NON-AQUEOUS SOLVENT EVAPORATION TECHNIQUE

Nanneboyina Sudeepthi and Sadhu Venkateswara Rao

ISBN: 978-81-980623-8-3

Department of Pharmaceutics,, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
nanneboyinasudeepthi@gmail.com

The aim of the present study was to design and optimize the floating microspheres of Captopril, an antihypertensive. Floating microspheres were prepared for the improvement of bioavailability of Captopril by retaining in the stomach for prolonged period of time by non-aqueous solvent evaporation technique using polymers like ethyl cellulose (EC) and Eudragit RS-100 in different ratios. The prepared floating microspheres were evaluated for micromeretic properities, percentage yield, in vitro buoyancy, drug entrapment efficiency and in vitro dissolution studies. Results showed that as the concentration of polymer increases it affects the particle size, percentage yield, In vitro buoyancy and drug release from the microspheres. Percentage yield of F6 microspheres was found up to 95.13%. The floating microspheres of optimized formulation F6 exhibited the prolonged drug release of 95.85% in sustained manner up to 24 hours and remain buoyant more than 12 hours. Formulation F6 follows zero order, non Fickian diffusion mechanism. Accelerated stability study was carried out for the optimized formulation and results showed that there were no significant changes in percentage drug entrapment efficiency, particle size, percentage buoyancy and In vitro controlled release of Captopril. The surface morphology analysis formulation F6 showed a hollow spherical structure with a smooth surface morphology. The developed floating microsphere system is a promising floating drug delivery system for oral sustained administration of Captopril.

**Keywords**: Antihypertensive, Micromeretics, Buoyancy and Non Fickian diffusion.

**PC-710**

## UNRAVELLING FORMULATION COMPLEXITY: THE CRUCIAL ROLE OF DISSOLUTION TECHNIQUE OF NOVEL CONTROLLED RELEASE AMORPHOUS SOLID DISPERSION (CASD)

Sandipan Roy, Sujata Sawarkar
Department of Pharmaceutics, SVKM's Dr. Bhanuben Nanavati college of Pharmacy, Vile Parle West, Mumbai 400056
sandepanroy@gmail.com

Dissolution testing plays a critical role in oral drug product development, serving as a bridge between formulation design, material properties, and process parameters to predict in vivo performance. As development progresses, dissolution methods must evolve to assess formulation robustness, detect manufacturing changes, and guide risk mitigation. This study focuses on optimizing a discriminatory dissolution method for a controlled-release formulation of Apremilast, a poorly soluble drug. Apremilast was processed via hot-melt extrusion with co-povidone (Kollidone VA64) at a 1:2 ratio to form an amorphous solid dispersion. This dispersion was further formulated with Hypromellose (Methocel K100 LVCR), glidant, and lubricant to develop a once-daily tablet as Controlled Release Amorphous Solid Dispersion (CASD). Initial solubility screening identified pH 4.5 acetate buffer as the most suitable medium, though it failed to maintain sink conditions alone. A series of dissolution experiments were conducted to refine test parameters. Surfactant concentration, agitation speed, apparatus type, and pH were systematically varied. Complete dissolution was achieved with 1% Tween 80, while higher concentrations accelerated release undesirably. Agitation at 75 rpm provided optimal discrimination, and USP-2 (paddle) apparatus outperformed USP-1 (basket) due to superior hydrodynamics. Among tested media, pH 4.5 acetate buffer ensured complete and sustained release over 24 hours. The final method—1% Tween 80 in pH 4.5 acetate buffer, USP-2 apparatus at 75 rpm, 900 ml volume—offers robust discriminatory power, enabling detection of formulation or process variations in Apremilast controlled-release amorphous solid dispersions.

**Keyword**: Poorly soluble drug, Apremilast, Controlled Release Amorphous Solid Dispersion, hot-melt extrusion, Discriminatory dissolution Method,

**PC-711**

## "INTRANASAL IN-SITU GEL OF VITAMIN B12: A SMART APPROACH FOR IMPROVED BIOAVAILABILITY"

Swara Patel, Mehul N Patel, Tejal Soni, B N Suhagia
Department of Pharmaceutical Science, Dharmsinh Desai University, Nadiad, Gujrat, India- 387003

Vitamin B12 deficiency is a major global health concern, as highlighted by WHO, affecting millions worldwide and leading to neurological, hematological, and metabolic disorders. Conventional oral and injectable dosage forms often face limitations such as poor absorption, invasive administration, and low patient compliance, necessitating innovative drug delivery systems that improve bioavailability, therapeutic outcomes, and acceptability. This study aimed to develop and characterize intranasal in-situ gel formulations of Methylcobalamin to provide a non-invasive and targeted therapy for Vitamin B12 deficiency. Pilot studies were conducted for the selection of suitable polymers and excipients. The selected formulation, prepared using poloxamer 407 (2.7 g) and chitosan (0.15 g), demonstrated desirable properties, including neutral pH (7.4), rapid sol-to-gel transition at physiological temperature (36 ± 2 °C), and adequate viscosity to ensure prolonged retention on nasal mucosa. In vitro diffusion studies revealed sustained Methylcobalamin release up to 4 hours (78.55% CDR), indicating favorable conditions for intranasal administration. The intranasal route bypasses hepatic first-pass metabolism, thereby improving systemic bioavailability and providing faster onset of action compared to conventional oral forms. Additionally, chitosan contributed to enhanced mucoadhesion, increasing residence time and promoting efficient drug absorption across the nasal epithelium. Overall, the findings suggest that intranasal in-situ gel systems represent a promising alternative for controlled Methylcobalamin delivery. Such formulations may enhance therapeutic efficacy, improve patient compliance, and offer an effective strategy for the management of Vitamin B12 deficiency.

**Keywords**: Intranasal delivery, In-situ gel, Vitamin B12 deficiency, Mucoadhesion, Controlled release

**PC-712**

## DESIGN AND CHARACTERIZATION OF BUCCAL TABLETS OF TRAMADOLOL HYDROCHLORIDE

Jaladi Hema and V.Saikishore
Department of Pharmaceutics,Bapatla College of Pharmacy, Bapatla-522101
jaladihema05@gmail.com

The aim of present research work is to formulate and evaluate buccal tablets of Tramadolol hydrochloride in view to enhance bioavailability and therapeutic action.The tablets were formulated by employing Moringa oleifera , gum kondagogu, Karaya gum.The powder blend was evaluated for flow properties. All the formulations showed values within the prescribed limits for tests like hardness, friability and weight variation which indicate that the prepared tablets are of standard quality. Tramadol hydrochloride buccal tablets prepared with karaya gum in 1:1.25 ratios shows more prolonged drug release compared with the other gums. Surface pH of all formulations was found to be in the range of 6.12 - 6.82, which were nearer to the salivary pH 6.8. Hence it was assumed that these formulations do not cause any irritation to the mucous layer of oral cavity The correlation coefficient values (r) revealed that the dissolution profiles followed Zero order kinetics and the mechanism of drug release was governed by Higuchi model. The n values are found to be more than 0.5 (n>0.5) indicted that the drug release was predominantly controlled by non fickian diffusion. It was found that an increase in concentration of polymer increases the ex vivo Mucoadhesive residence time. The present study revealed that karaya gum appears to be suitable for use as a release retardant in the manufacture of buccal tablets because of its good swelling, good flow rate and suitability for mucoadhesion formulations.

**Keywords**: Tramadolol hydrochloride, Moringa oleifera, Gum kondagogu, Karaya gum

## ROPINIROLE HCl LOADED NARASTRUCTURED LIPID CARRIERS FOR INTRANASAL DELIVERY TO TREAT PARKINSON'S DISEASE: FORMULATION, OPTIMIZATION, IN VITRO AND IN VIVO STUDY

Rutuja Kumbhar, Mukesh Ratnaparkhi, Prachi Jadhv , Arti Dhakane
Marathwada Mitra Mandal's College of Pharmacy, Thergaon, Pune, Maharashtra-411033
rutujakumbhar065@gmail.com

ISBN: 978-81-980623-8-3

Parkinson's disease is a progressive neurodegenerative disorder associated with degeneration of dopaminergic neurons, leading to motor impairment and functional decline. Ropinirole hydrochloride, a dopamine agonist, is clinically used to manage symptoms; however, its therapeutic potential is limited by extensive first-pass metabolism, low oral bioavailability, and short half-life. To overcome these drawbacks, nanostructured lipid carriers (NLCs) were developed and optimized for intranasal delivery, enabling direct nose-to-brain transport and bypassing the blood–brain barrier (BBB). The optimized batch demonstrated favorable physicochemical properties, with a mean particle size ranging from 122.1 ± 0.74 to 180.2 ± 0.44 nm, entrapment efficiency (EE) between 65.24 ± 0.44% and 85.21 ± 0.43%, and zeta potential (ZP) from –17.12 ± 1.50 to –36.25 ± 0.84 mV, confirming stability and uniformity of the formulation. In-vitro release studies revealed a sustained profile, with the optimized formulation achieving 98.6 ± 0.61% drug release over 180 min, demonstrating controlled and prolonged drug availability. Pharmacological evaluation further showed that ropinirole-loaded NLCs achieved higher brain uptake, improved pharmacokinetic performance, and enhanced neuroprotective effects compared to conventional dosage forms. Enhanced motor coordination, prolonged therapeutic action, and reduced systemic toxicity were observed in Parkinson's disease models. Overall, the optimized ropinirole hydrochloride NLC formulation demonstrates significant promise as a brain-targeted delivery system. By improving solubility, stability, and CNS bioavailability, it represents a novel therapeutic approach for Parkinson's disease. Future work should focus on large-scale manufacturing, long-term stability, and clinical translation to establish its utility in neuropharmaceutical therapy.

**Keywords**: Ropinirole hydrochloride, Nanostructured lipid carriers, Parkinson's disease, Blood–brain barrier, Intranasal delivery.

## DESIGN AND EVALUATION OF CONTROLLED RELEASE MATRIX TABLETS FOR VALPROIC ACID AND SODIUM VALPROATE

Charru Sharma1, Ruchi Suyal2, Viney Chawla1
University Institute of Pharmaceutical Sciences and Research, BFUHS, Faridkot, Punjab, India-151203
sharmacharru23@gmail.com

This study focused on the design and evaluation of matrix tablets containing sodium valproate, aiming to achieve controlled drug release. Sodium valproate is commonly used in managing epilepsy and bipolar disorder, conditions requiring steady plasma drug levels for effective treatment. Controlled release tablets of sodium valproate and valproic acid were prepared based on the pharmacokinetic data of the medication. The formulation included matrix tablets prepared using range of excipients in different proportions to modulate drug release. The drug-polymer blends were tested for physical properties such as hardness, weight variation, friability, and drug content. In vitro dissolution studies were performed to assess the drug release profiles over time. Stability studies conducted over two months indicated that the optimized formulation maintained its integrity and performance without significant changes. The matrix tablets are expected to reduce dosing frequency and improve patient compliance. Such systems are beneficial for managing chronic conditions requiring long-term medication, reducing the risk of side effects associated with peak drug levels and ensuring better therapeutic outcomes. Different batches were prepared with varied quantities of excipients. Based on comparative evaluation, formulation batch 6 was identified as optimized batch in which Hydroxy propyl methyl cellulose K15(HPMC K15) was incorporated as modified release polymer. The controlled release formulation offered a practical and stable alternative to conventional dosage forms, contributing to improved patient management and treatment adherence.

**Keywords**: Sustained drug release, Bipolar disorder, Stability studies, Optimized formulation

## "DEVELOPMENT AND CHARACTERIZATION OF ADVANCED DRUG DELIVERY SYSTEM FOR TARGETED VITILIGO THERAPY."

Rani Katekar, Isha Kavedia, and Janhvi Shetty
under the guidance of Dr. Mohammad Wais sir.
Department of Pharmaceutics, H.K College of Pharmacy, Mumbai, Maharashtra, India-400102

Vitiligo is a chronic autoimmune pigmentary disorder characterized by the progressive destruction of melanocytes, resulting in depigmented skin patches and profound psychosocial distress. Conventional therapeutic approaches such as corticosteroids, phototherapy, and immunomodulators often suffer from limited efficacy, high relapse rates, and poor patient adherence, underscoring the urgent need for more effective strategies. This study presents a novel transdermal drug delivery platform, engineered to overcome the limitations of existing treatments and deliver precise, sustained therapeutic action. The proposed system incorporates advanced carriers including liposomes, niosomes, and nanoparticle-loaded hydrogels, designed to stabilize therapeutic agents, enhance skin permeation, and enable targeted delivery at the epidermal–dermal junction the critical site of melanocyte activity. The formulation is developed within a Quality by Design (QbD) framework, ensuring robustness, reproducibility, and patient safety. Beyond drug delivery, the system is strategically designed to protect residual melanocytes, reduce oxidative stress, and regulate autoimmune pathways, thereby creating a favourable microenvironment for repigmentation. Comprehensive characterization studies including vesicle morphology, particle size distribution, entrapment efficiency, in vitro drug release, stability, and cytocompatibility—will provide insights into performance and therapeutic potential. By integrating nanotechnology with a mechanistic understanding of vitiligo pathogenesis, this approach offers a non-invasive, patient-friendly treatment capable of promoting sustained repigmentation, minimizing relapse risk, and significantly improving patient quality of life. Ultimately, this innovative delivery system marks a significant advancement in developing safe, effective, and reliable treatment strategies for vitiligo.

**Keywords**: Vitiligo, Nanocarrier delivery, Transdermal therapy, Repigmentation, Oxidative stress modulation, Immunomodulation.

## IN-VITRO EVALUATION OF POSACONAZOLE LOADED SLN GEL FOR IMPROVED BIOPHARMACEUTICAL PERFORMANCE

Anmol Singh, Honey Goel, Neetu Kukar and Richu Singla
Baba Farid University of Health Sciences, Faridkot, Punjab-151203, India.
aannmol250@gmail.com

Oral candidiasis, particularly common in immunocompromised patients, represents a major fungal infection that can progress to systemic bloodstream involvement if left untreated, with Candida albicans responsible for nearly 60% of cases and non-albicans species accounting for 40–53%. however, conventional antifungal therapies such as fluconazole suspensions, clotrimazole tablets, and nystatin rinses are limited by rapid oral clearance, inconsistent drug delivery, and systemic absorption leading to adverse effects including QTc prolongation and nephrotoxicity, while resistance mediated through efflux transporters of Candida albicans. Posaconazole, a potent triazole antifungal with markedly lower MIC values and reduced susceptibility to efflux mechanisms, offers therapeutic advantages but is restricted by poor aqueous solubility (BCS Class II), pH-dependent intestinal precipitation, and systemic toxicities such as QTc prolongation, steroid synthesis inhibition, and pseudoaldosteronism. To overcome these limitations, a solid lipid nanoparticle (SLN)-based mucoadhesive gel was developed using solvent emulsification with high-speed stirring and bath sonication, optimized via fractional factorial design for localized action in the oral cavity. The drug's solubility was determined in various solid lipids and was found to be maximum in glyceryl monostearate. The optimized SLN batch showed a particle size suitable for buccal mucosal penetration <200 nm, favoring interaction with negatively charged mucosa, with good entrapment efficiency and drug loading. Further the optimized SLN-loaded gel exhibited a pH of 6.8, with swelling index of 58.45% after 6 hours. The rheological analysis revealed pseudoplastic shear-thinning behavior at 37 °C. In vitro release studies demonstrated sustained release, while ex vivo evaluation confirmed superior buccal retention and strong mucoadhesive strength, enabling prolonged mucosal adherence. These findings highlight the potential of the SLN-based mucoadhesive gel for localized, controlled delivery of posaconazole in oral candidiasis with reduced systemic toxicity.

**Keywords**: Solid lipid nanoparticles, oral candidiasis, mucoadhesive gel, candida albicans, buccal mucosa

**DEVELOPMENT AND OPTIMIZATION OF A PRONIOSOMAL GEL FOR TRANSDERMAL DELIVERY OF ALENDRONATE SODIUM: A NOVEL APPROACH FOR OSTEOPOROSIS MANAGEMENT**

Isha Kavedia, Pratibha Patil, Rani Katekar, Janhvi Shetty, Jaya Agnihotri
Department of Pharmaceutics, H.K College of Pharmacy, Mumbai, Maharashtra, India, 400102
ishamk12@gmail.com

Osteoporosis is a widespread metabolic bone disease affecting over 200 million people worldwide, characterized by decreased bone mass and increased fracture risk, leading to significant morbidity, mortality, and healthcare costs. Alendronate sodium (ALS), a widely prescribed bisphosphonate, is effective in inhibiting bone resorption and reducing fracture risk, making it a cornerstone in osteoporosis treatment. However, ALS's poor oral bioavailability and gastrointestinal side effects often limit patient adherence and long-term therapeutic success. This study proposes a novel proniosomal gel formulation for the transdermal delivery of ALS, designed to overcome these limitations by enhancing drug solubility, improving skin permeation, and providing sustained release. The formulation (FI-F13) was optimized using a Design of Experiments (DoE) approach to systematically to evaluate the influence of formulation variables on key quality attributes such as entrapment efficiency and drug release. This innovative delivery system aims to maintain consistent therapeutic drug levels while minimizing systemic side effects associated with oral administration. The mean particle size, drug release, entrapment efficiency and stability indicate that proniosomal gels can effectively facilitate ALS absorption through the skin, offering a non-invasive, patient-friendly alternative to conventional oral therapies. Furthermore, the formulation approach holds promising potential for scalable manufacturing, which could accelerate its translation into clinical use. Overall, proniosomal gel-based delivery of ALS represents a promising advancement in osteoporosis management, with the potential to improve patient compliance, enhance treatment efficacy, and ultimately contribute to better long-term outcomes.

**DEVELOPMENT OF A QUERCETIN-LOADED PLGA-BASED DRY POWDER INHALER: FORMULATION AND IN VITRO PERFORMANCE**

Shalini Das1, Trideep Saikia1
1Department of Pharmaceutical Sciences, Girijananda Chowdhury University-Guwahati Campus, 781017, Assam, India

The development of inhalable nanocarrier-based systems provides a promising approach to tackling the challenges of poor drug delivery and resistance in lung cancer therapy. In this study, quercetin (QCT) was co-encapsulated into PLGA nanoconjugates using the single emulsion solvent evaporation (SESE) method to achieve synergistic anticancer effects. The optimised formulation showed a mean particle size of 165.12 ± 22.23 nm with uniform distribution and high encapsulation efficiency, exceeding 84%. To facilitate pulmonary delivery, the nanoconjugates were transformed into a dry powder inhaler (DPI) formulation using a carbohydrate-based carrier. The DPI exhibited favourable aerodynamic characteristics, with a mass mean aerodynamic diameter of 4.32 µm and a fine particle fraction above 60%, ensuring efficient deep lung deposition. In vitro release studies demonstrated a sustained biphasic release of QCT, confirming the potential of the system for prolonged therapeutic action. These findings highlight the feasibility of QCT-loaded DPI as a novel inhalable platform for effective pulmonary drug delivery.

**Keywords**: Quercetin, PLGA nanoconjugates, Dry powder inhaler, Pulmonary drug delivery

**A REVIEW ON IN VITRO-EVALUATION OF MICROCELLULOSE HYDROGEL FOR POST-OPERATIVE SCARS PREPARED FROM EXTRACTED MICROCELLULOSE USING PINEAPPLE PEELS**

VAIBHAV K. KAKDE
vaibhavkakde14@gmail.com

The present study focuses on the development of a sustainable, plant-based hydrogel for post- operative scar management using microcellulose extracted from pineapple peels, an abundant agro-industrial waste. The project aims to convert this biodegradable waste into a value-added pharmaceutical product with topical wound-healing potential. Pineapple peels were subjected to drying and powdering, followed by chemical treatment involving delignification with sodium hydroxide, bleaching with sodium hypochlorite, and acid hydrolysis using hydrochloric acid to isolate microcellulose. The obtained microcellulose was incorporated into a hydrogel formulation using Carbopol 940 as the gelling agent. Aloe vera extract was included for its known soothing and regenerative properties, polyethylene glycol 400 (PEG-400) was used as a humectant to retain moisture, phenoxyethanol acted as a preservative, and triethanolamine was employed to adjust and stabilize the pH of the formulation. The final hydrogel was evaluated for essential parameters such as physical appearance, spreadability, viscosity, pH sensitivity, and homogeneity to determine its suitability for topical application. The formulation exhibited desirable characteristics, including uniform texture, ease of application, and skin-compatible pH, indicating its potential as an effective scar management product. This research not only presents a novel formulation for wound care but also contributes to environmental sustainability by repurposing organic waste. Overall, the study supports the development of cost-effective, eco-friendly alternatives in dermatological therapy. Further investigation through biological evaluations and clinical studies is recommended to validate its therapeutic efficacy and commercial applicability.

**Keywords**: Microcellulose, Pineapple Peels, Hydrogel, Post-Operative Scar, Topical Delivery, Sustainable Formulation, Aloe Vera, Carbopol 940

**DEVELOPMENT AND EVALUATION OF AGMATINE LOADED CUBOSOMES FOR INTRANASAL DELIVERY IN THE TREATMENT OF EPILEPSY**

Gopal Ashok Bhagat, Om Bhurbhure, Jayshree B. Taksande, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India-441001
bhagatgopal2003@gmail.com

Epilepsy, a prevalent neurological disorder characterized by recurrent seizures, remains challenging to manage due to pharmacoresistance and systemic side effects associated with conventional antiepileptic drugs. Agmatine, a naturally occurring polyamine with NMDA receptor antagonism and neuroprotective properties, shows promise in seizure control but suffers from poor bioavailability and limited blood-brain barrier (BBB) permeability. This study explores the potential of intranasal delivery of agmatine via cubosomes a lipid-based nanocarrier system to overcome these limitations and enhance brain targeting. Agmatine-loaded Cubosomes were prepared using glyceryl monooleate and Pluronic® F127 and characterized for particle size, zeta potential, entrapment efficiency, and structural morphology. The optimized formulation (F7) exhibited a nanoscale particle size (270.4 nm), negative zeta potential (−12.0 mV), and high entrapment efficiency (88.92 ± 0.33%). FTIR, DSC, and XRD analyses confirmed successful drug encapsulation and reduced crystallinity, indicating molecular dispersion of agmatine. In vitro studies demonstrated sustained drug release over 12 hours. In vivo evaluation in a pentylenetetrazol (PTZ)-induced seizure model in mice showed that intranasal agmatine-loaded cubosomes significantly delayed seizure onset (611 ± 3.3 s) and reduced convulsion duration (16 ± 5.3 s), outperforming both free agmatine and standard diazepam treatments. These findings support the efficacy of cubosome-based intranasal delivery as a non-invasive, brain-targeted therapeutic strategy for epilepsy and highlight its potential to enhance clinical outcomes while minimizing systemic side effects.

**Keywords**: Agmatine, Cubosomes, Intranasal, Drug delivery, Epilepsy, Blood-brain barrier.

prachidhirendra09@gmail.com

Wound healing poses an enormous challenge, in the healthcare society and nanotechnology-based formulations for acute and chronic wound healing due to their advanced delivery of therapeutic substances. This study aimed to develop a stable hydrogel with essential oils for wound healing. Essential oils Including curcumin, eucalyptus, and sandalwood oil were individually added to the CMC hydrogel and in combination. The formulations underwent further analysis to assess their physicochemical properties, rheological measures, stability, dermal toxicity, and in vivo wound healing efficacy. The findings indicated that all essential oil-loaded hydrogels were stable and did not produce any signs of toxicity during the 48-hour observation period following the application of the hydrogel to the shaved skin of rats. The rats were randomly grouped, and wounds with a diameter of 1 cm were created on their skin using the excision method. Subsequently, the wounds were treated with the respective treatments for 14 days. The results indicated that the combination of oil-loaded hydrogels more effectively reduced the wound area compared to individual oil hydrogels. Additionally, the combination showed faster healing action compared to the commonly used marketed nanocrystalline silver gel and completely eradicated scarring on the skin after 14 days of the experiment. The results indicated that the combination of oil-loaded hydrogels more effectively reduced the wound area compared to individual oil hydrogels. Additionally, the combination showed faster healing than the commonly used marketed nanocrystalline silver gel and completely eradicated scarring on the skin after 14 days of the experiment. Among the individual oil hydrogels, the sandalwood oil hydrogel exhibited a higher potential for wound healing and scar removal. Each selected oil possessed distinct medicinal properties, including anti-inflammatory, antioxidant, antimicrobial, and tissue regeneration capabilities, and their combination enhanced the wound healing efficacy. In conclusion, the essential oil-loaded hydrogel exhibits significant potential for wound healing, and the combination of oils can synergistically enhance its action. Therefore, further research is needed on a larger scale to explore its potential utilization in wound dressing.

**Keywords**: CMC- Hydrogel, Essential Oil, Wound healing, In Vivo

## SMART BUCCAL FILMS FOR CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHY MANAGEMENT: CCD-BASED OPTIMIZATION WITH EX-VIVO PERMEATION AND STABILITY PROFILING

Saniya Jawed and Swathi Vijaya P
PESU Institute of Pharmacy, PES University, Electronic City campus, Bengaluru, Karnataka, India – 560100.

Chemotherapy-induced peripheral neuropathy (CIPN) is a dose-limiting adverse effect of multiple chemotherapeutic agents and causes damage to the peripheral neurons. Duloxetine, a serotonin-norepinephrine reuptake inhibitor (SNRI), is considered a first-choice of drug to reduce the pain in CIPN by increasing the levels of these neurotransmitters in the central nervous system and modulating pain perception. Oral formulations of duloxetine are not so effective due to lower bioavailability (~50%), extensive first-pass metabolism, GIT degradation, and less absorption. To overcome these limitations, a buccal patch of duloxetine has been prepared in this research work by the solvent cast method. A central composite design (CCD) was applied with concentrations of HPMC K4M, HPMC K15M, and PEG 400 as independent variables. The swelling index (%) and folding endurance were considered as dependent variables. Formulations were assessed for surface pH, thickness, folding endurance, mucoadhesion strength, in vitro drug release, and drug content. The optimized batch showed a swelling index of 82% and folding endurance of 240, with 97.80 ± 1.23 % drug content. In-vitro drug release study confirms 96.61 ± 1.14 % of drug release in 200 minutes and 32.23 ± 0.02 mg as mucoadhesion strength. Ex-vivo study also confirms the penetration of 78.25 ± 1.07% of the drug in 4 hours with oleic acid as a penetration enhancer. The developed buccal film proves a novel and scalable drug delivery approach with improved bioavailability scope, ensures a quicker therapeutic action, and enhances patient compliance in CIPN management with reduced systemic toxicity.

**Keywords**: Duloxetine, chemotherapy-induced peripheral neuropathy, buccal patch, and Central Composite Design.

**PC-723**

## FORMULATION AND EVALUATION OF ZOLMITRIPTAN NASAL SPRAY FOR RAPID MIGRAINE RELIEF

Dr. Asha Rani M1, Hikshitha DP2, Hemanth Kumar Y2, Chethan Gowda M2, Shambhavi D2, Suprith Gowda GN2,
Department Of Pharmaceutics, Visveswarapura Institute of Pharmaceutical Sciences, Bengaluru 560070, India.

Migraine is a common neurovascular disorder characterised by severe headaches and associated symptoms such as nausea and photophobia. Oral triptans like zolmitriptan can be effective but may have a delayed onset due to gastric stasis during migraines. Nasal drug delivery can bypass gastrointestinal absorption, offering rapid relief. Zolmitriptan nasal spray formulations were prepared using different polymers (hydroxypropyl methylcellulose, methylcellulose, or chitosan) as viscosity modifiers. Formulations were characterised for pH, viscosity, spray content uniformity, in vitro drug diffusion through the nasal membrane, and drug-excipient compatibility (FTIR spectroscopy). A UV spectrophotometric method was employed to quantify the drug, following the construction of a calibration curve of zolmitriptan in a pH 5.8 phosphate buffer. All formulations exhibited a pH ranging from 5.5 to 6.0, optimised for the nasal mucosa, and demonstrated uniform drug content. Fourier Transform Infrared (FTIR) spectroscopy confirmed the compatibility of zolmitriptan with excipients. In-vitro diffusion studies indicated that the formulation containing chitosan (F3) released approximately 20% of the drug within 5 minutes and about 62% in 85 minutes, significantly faster than formulations with HPMC or MC. The rapid release observed in F3 was correlated with a quicker onset of action. The spray delivered approximately 0.15 mL per actuation, maintaining consistent dosing. A zolmitriptan nasal spray with chitosan as a mucoadhesive polymer provides rapid drug release, achieving significant drug diffusion within minutes. This formulation offers a promising approach for quick relief in acute migraine, potentially benefiting patients who require a rapid onset of effect and those with migraine-induced gastric stasis. The nasal route thus combines the efficacy of zolmitriptan with an improved delivery profile for managing acute migraine.

**Keywords**: Zolmitriptan, Migraine, Nasal spray, Triptan, Chitosan, In-vitro diffusion, Rapid release

**PC-724**

## DEVELOPMENT OF FAST DISSOLVING ORODISPERSIBLE FILMS LOADED WITH RESVERATROL EXTRACT

Peram Mounika and Sadhu Venkateswara Rao
Department of Pharmaceutics
Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
vipwpmounika92@gmail.com

Resveratrol, a naturally occurring polyphenolic compound with strong antioxidant and therapeutic properties, has shown great potential in the management of various diseases. However, its clinical application is limited due to poor aqueous solubility, low stability, and reduced oral bioavailability. To overcome these challenges, fast dissolving orodispersible films (ODFs) loaded with resveratrol extract were developed as an alternative dosage form to enhance patient compliance and improve drug performance. Resveratrol was extracted from natural sources using ethanol by reflux technique, and the crude extract was characterized to confirm the presence of active constituents. The formulation of ODFs was optimized using hydroxypropyl methylcellulose (HPMC) as the film-forming polymer and propylene glycol as a plasticizer, with varying concentrations of resveratrol extract incorporated. The prepared films were evaluated for physicochemical properties, disintegration time, mechanical strength, and drug release. The optimized formulation containing 2.5% HPMC, 1.5% propylene glycol, and resveratrol extract demonstrated desirable film characteristics. The films disintegrated rapidly within 20 seconds when tested using a disintegration apparatus, ensuring quick drug release and enhanced absorption. Mechanical property testing confirmed that the films were strong, flexible, and non-brittle, making them suitable for handling and administration. Overall, the study indicates that fast dissolving

ISBN: 978-81-980623-8-3

orodispersible films loaded with resveratrol extract can serve as a promising alternative to conventional dosage forms, offering improved solubility, rapid disintegration, and enhanced therapeutic potential of resveratrol.

**FORMATION EVALUATION OF GASTRO RETENTIVE DRUG DELIVERY SYSTEM OF LOSARTANBPOTASSIUM BY USING RAFT FORMING TECHNIQUE**

MAJJI.AMRUTHA CH.SANDHYA RANI
VIKAS INSTITUTE OF PHARMACEUTICAL SCIENCES Nidigatla Road, Near Airport Rajahmundry, E.G Dist. AP - 533102 (NAAC Accredited , Approved by AICTE & PCI, New Delhi, Affiliated to Andhra University, Vizag)
majjiamrutha2004@gmail.com

Hypertension is a chronic cardiovascular disorder that demands effective and sustained management through safe and patient-friendly drug delivery systems. Losartan potassium, an angiotensin II receptor antagonist, is widely prescribed for hypertension and related cardiovascular conditions. However, conventional oral administration of Losartan potassium often faces limitations such as reduced bioavailability and frequent dosing due to its short half-life. To overcome these drawbacks, the present study focuses on the formulation and evaluation of Losartan potassium tablets using a raft forming technique under novel drug delivery systems. The raft forming system is a gastro-retentive drug delivery approach that, upon contact with gastric fluid, swells and forms a viscous gel-like raft capable of floating in the stomach. This provides prolonged gastric residence time, ensures localized drug release, and enhances bioavailability. In this study, Losartan potassium tablets were prepared with suitable polymers such as sodium alginate and hydroxypropyl methylcellulose (HPMC), along with calcium carbonate and sodium bicarbonate as gas- generating agents. The formulations were optimized to achieve desirable parameters including tablet hardness, friability, swelling index, floating lag time, and total floating duration. The prepared tablets were evaluated for their physicochemical properties, drug content uniformity, in vitro buoyancy, and sustained release profile. Results demonstrated that the optimized formulation exhibited rapid raft formation with minimal floating lag time, remained buoyant for more than 12 hours, and showed a controlled and sustained drug release profile, meeting pharmacopoeial specifications.

**Keywords**: Hypertension, Losartan potassium, Raft forming system, Gastro-retentive drug delivery.

**FORMULATION, EVALUATION AND ASSESSEMENT OF TRIDAX PROCUMBENS TOPICAL CREAM FOR TINEA PEDIS (ATHLETE'S FOOT).**

Parijat Pandey and Harish Dureja
Department of Pharmaceutical Sciences, Maharshi Dayanand University, Rohtak, Haryana, India- 124001.
parijatpandey98@gmail.com

A superficial fungal infection of the feet is called tinea pedis, or athlete's foot. Its frequency in a 1999 prospective epidemiological research in Hong Kong was 20.4% in 1014 participants. One Males, middle-aged or older people, people with diabetes, and pesssople with other underlying medical conditions (especially immune system issues) that encourage fungus development are more likely to have tinea pedis. The dermatophytes Trichophyton mentagrophytes, Trichophyton rubrum, and Epidermophyton floccosum are the most frequent causative organisms. Topical antifungals including ketoconazole, terbinafine, econazole, and cicloprox creams, as well as oral medications like griseofulvin, itraconazole, fluconazole, and terbinafine, are used to treat tinea pedis. Alternative medications may be preferable because of their limited range of action, drug resistance, toxicities, and combinations with other drugs. According to an assessment of the antifungal properties of more than 1000 species of TCMs listed in the 2005 edition of the Pharmacopoeia of the People's Republic of China, 83 of them have been shown to have antifungal properties, with 11 of them being effective against strains of Trichophyton. These consist of Folium Eucalypti Globuli [FEG], Fructus Psoraleae [FP], Fructus Chebulae, Herba Cichorii, Rhizoma Curcumae Longae [RCL], Semen Juglandis, Herba Portulacae, Bulbus Allii, Fructus Galangae, Tidax procunbens [TP] and Semen Cassiae. In this article we use a herbal plant Tidax procumbens possess antifungal property and we prepare a herbal topical formulation for the treatment of tinea pedis.

**Keywords**: Tinea pedis, Athlete's foot, Superficial fungal infection, Dermatophytes, Trichophyton, Traditional Chinese Medicine (TCM), Tidax procumbens, Herbal formulation, Antifungal activity, Topical treatment.

**ECO-FRIENDLY SYNTHESIS AND CHARACTERIZATION OF GOLD NANOPARTICLES FROM BUCHANANIA LANZAN WITH ANTICANCER ACTIVITY**

Dr. Akila E1, Mrs. Netravati Deshpande1
1Dept. of Pharmacognosy, Al-Ameen College of Pharmacy, Bangalore-27.
akila.aacp@gmail.com

The present study investigated the pharmacognostical, phytochemical, and anticancer potential of Buchanania lanzan leaves and their phenolic-rich fractions for green nanoparticle synthesis. Leaves collected from Andhra Pradesh were shade-dried, powdered, and subjected to successive Soxhlet extraction with solvents of increasing polarity. Preliminary analysis confirmed the presence of phenolic compounds, with the ethanolic extract showing the highest total phenolic content (73.32 ± 0.86 mg GAE/g). The phenolic-rich fraction was employed for eco-friendly biosynthesis of gold nanoparticles (AuNPs), indicated by a ruby-red colour change and characterised using UV–Vis, FTIR, SEM, TEM, and XRD techniques. AuNPs were predominantly spherical (10–200 nm) and stabilised by phytoconstituents. In vitro cytotoxicity against HeLa cervical cancer cells was assessed by MTT assay. BL-AuNPs and phenolic fractions showed dose-dependent inhibition, with $IC_{50}$ values of 113.50 µg/mL and 216.90 µg/mL, respectively, compared with doxorubicin (22.61 µg/mL). Morphological observations confirmed apoptosis induction. In vivo studies using Dalton's Ascites Lymphoma (DAL) in Swiss albino mice demonstrated that BL-AuNPs suppressed tumour-associated weight gain, prolonged mean survival time, and increased lifespan, comparable to 5-fluorouracil. Treatment also restored antioxidant enzymes (SOD, CAT), reduced lipid peroxidation, and normalised liver function markers. Haematological parameters and histopathological analysis further confirmed protection of hepatic and hematopoietic systems. Overall, Buchanania lanzan-mediated AuNPs exhibited notable anticancer efficacy by inhibiting tumour growth, restoring antioxidant defences, and protecting vital functions, highlighting their potential as safe, natural therapeutic agents.

**Keywords**: Buchanania lanzan, phenolic-rich fraction, gold nanoparticles, anticancer activity, HeLa cells.

**ENHANCING PERMEABILITY OF VILDAGLIPTIN VIA NANOEMULSION: ADVANCEMENTS IN DIABETES TREATMENT**

Mohit kapse1, Deepak Khobragade1*
Datta Meghe Institute of Higher Education and Research, Sawangi (Meghe), Wardha.

Vildagliptin, a potent dipeptidyl peptidase-4 (DPP-4) inhibitor, is widely prescribed for the management of type 2 diabetes mellitus. Despite its therapeutic effectiveness, its oral bioavailability is limited due to poor permeability across gastrointestinal membranes and extensive first-pass metabolism. These drawbacks necessitate frequent dosing, which can compromise patient compliance and therapeutic efficiency. Recent advancements in nanotechnology-based drug delivery systems, particularly nanoemulsions, have emerged as a promising approach to address these limitations. Nanoemulsions are colloidal dispersions with droplet sizes typically below 200 nm, offering a large surface area and improved solubilization of lipophilic drugs. Their unique physicochemical properties enable enhanced drug permeation through biological membranes, protection from enzymatic degradation, and controlled release, thereby improving the pharmacokinetic profile of encapsulated agents. Formulating Vildagliptin into a nanoemulsion system can significantly enhance its permeability, leading to improved absorption and increased oral bioavailability. This novel approach not only reduces dosing frequency but also ensures more consistent therapeutic plasma

ISBN: 978-81-980623-8-3

concentrations, minimizing side effects associated with fluctuating drug levels. Additionally, the biocompatibility and scalability of nanoemulsion systems make them suitable candidates for clinical translation. Several in vitro and in vivo studies have highlighted their ability to improve drug transport across intestinal barriers and sustain hypoglycemic activity more effectively than conventional formulations. In conclusion, nanoemulsion-based delivery of Vildagliptin represents a novel and rational strategy to overcome the challenges of conventional therapy. By enhancing permeability and bioavailability, this approach offers a potential advancement in diabetes treatment, aiming to improve patient outcomes, adherence, and overall therapeutic success.

**PC-729**

**ADVANCEMENTS IN EGG NANOPARTICLE TECHNOLOGY FOR ENHANCED DRUG DELIVERY SOLUTIONS**

Tejal lokhande1, Deepak Khobragade1*
Datta Meghe Institute of Higher Education and Research, Sawangi (Meghe), Wardha.

Egg nanoparticles have been discovered as drug delivery vehicles that are biocompatible, biodegradable, and highly scalable compared to other types of nanocarriers. In the current days, the new methods of fabrication, surface treatment and functionalization have improved their application in nanomedicine. The aim of this review includes discussing the current state of knowledge about the properties and characterization of the egg nanoparticle-based drug delivery system, and the functions of these systems in cancer treatment, infectious diseases, and neurological diseases. Pros of egg nanoparticles such as enhanced pharmacokinetics, sustained release, and low toxicity are presented with limitations on scale up, immunogenicity, and the regulatory environment. Other current topics cantered on pharmacological approaches include combination therapy and multifunctional nanoparticles. Lastly, the review section points to the future studies and application of egg nanoparticle-based drug delivery systems and claims that more development and research is needed to revolutionize the system of medicine delivery and the life expectancy of patients.

**DRONE ASSISTED DRUG DELIVERY SYSTEM...FOR VILLAGERS IN EMERGENCY CONDITIONS**

SANTOSH POLAMURI. *P.VASUBABU(Department of Analysis). Vikas institute of pharmaceutical sciences , Near airport Rajahmundry,East Godavari district, Andhra Pradesh, INDIA-533102
Chinnuchinnu1440@gmail.com

Access to essential medicines remains a significant challenge in rural and remote villages where poor road connectivity, geographic barriers, and lack of reliable transport hinder timely healthcare delivery. Delayed access to life-saving drugs such as vaccines, insulin, and snake-bite antivenom often leads to preventable morbidity and mortality. To address this gap, drone-assisted medicine delivery is emerging as an innovative and practical solution under novel healthcare logistics. Drones, also known as unmanned aerial vehicles (UAVs), can bypass difficult terrains and deliver small but critical medical supplies within minutes to hours, where conventional transport might take days. Equipped with GPS navigation, temperature-controlled storage, and real-time tracking, drones ensure the safe and rapid transportation of time-sensitive medications. This technology is especially beneficial in emergency situations, such as sudden outbreaks, natural disasters, or urgent treatment needs in villages with minimal healthcare infrastructure. The proposed system integrates drones with primary health centers (PHCs), local pharmacists, and community health workers, ensuring last-mile connectivity. Centralized drug hubs can dispatch essential medicines through drones to designated drop points or directly to healthcare workers in villages. This not only improves drug availability but also strengthens vaccination drives, chronic disease management, and emergency care in underserved regions. Recent pilot projects worldwide have demonstrated the feasibility of drone delivery in transporting blood, vaccines, and diagnostics, significantly reducing delays and saving lives. The integration of drone technology into national health systems could revolutionize rural healthcare delivery, making essential medicines more accessible, affordable, and timely. In conclusion, drone delivery of essential medicines represents a novel, cost-effective, and scalable approach to bridging healthcare inequity. By combining innovation with community health systems, this strategy can enhance rural healthcare outcomes and contribute to universal health coverage in resource-limited settings.

**IMPROVING BIOPHARMACEUTICAL EFFECTIVENESS OF THE ROSUVASTATIN BY UTILISING THE Qbd TECHNIQUE**

CHEKURI . LAVANYA DR.D.SRINIVASA SASTRY
VIKAS INSTITUTE OF PHARMACEUTICAL SCIENCES Nidigatla Road, Near Airport Rajahmundry,
E.G Dist. AP - 533102 (NAAC Accredited , Approved by AICTE & PCI, New Delhi, Affiliated to Andhra University, Vizag

Although statins are frequently given for hyperlipidemia, cancer, and Alzheimer's disense, they come with a number of inherent problems, including limited solubility, a greater rate of hepatie melabolism, low drug loading, and instability at the plH of the stomach. As a result, the significantly larger circulating dose neded to achieve therapeutic effiect causes severe dose-mediated toxsicity. Therefore, a Quality by Design(QbD)integrated strategy was used to design the statin-loaded new delivery system. Limicubes due to limited biocompatibility, toxicity, and other severe regulatory concerns such product conformance, reproducibility, and stability of existing formulations. Monoolein, Poloxamer, and stiring speed sigrificantly modulated amd improved performance of L.imicubes with respect to, Critical Quality Attributes (CQAsS), Ishikawa Fish-bone Diagram, Risk Assessment Matrix (REM), and Failure Mode and Effects Analysis (FMEA) based risk management approaches. The effects of the optimised formulation on the average particle size, (Y1=1.40-2. 70 µ) entrapment effectiveness, and drug loading were devcloped and characterised. The formulation that was subsequently created had improved pharmacokinetic and hypolipidemic cffectiveness, as well as a decreased adverse effect from loading rosuvastatin. A popular strategy used to develop is "Quality by Design" (QbD), It is based on the idea that quality should be built into the product from the start rather than just being finalised during production. The curent study describes a step- byestep implemenlation of QbD principles where speed, air presure, processing time, and bautch size (indcpendent paramcters) were initally recognishe ed as having high- to medium-impact on the dry coaing process, While several interaction factors had an impuct on content homogcneity, speed and batch size had the most detrimental effects. The updated model's validity and predictive power showed reliability for all experiments, QbD has been shown to be an efficient and affordable technique for creating and improving procedures in the pharmaceutical business overall.

Artificial intelligence (AI)-based drug discovery (DD) holds significant promise in overcoming longstanding challenges posed by the complexities of identifying novel therapeutics. This review examines the critical hurdles, methodologies, and trans formative potential of advanced AI platforms in streamlining the drug discovery process. Using the Dompas Escalate platform as a case study, the article demonstrates how AI-driven approaches enhance molecular candidate identification, improve prediction accuracy, and facilitate the development of targeted therapies. By integrating machine learning, deep learning, and high-performance computing with physics-based simulations, generative modeling, and vast molecular databases, AI platforms are enabling seamless collaboration between technological and biological domains. This convergence is reshaping the landscape of bio pharmaceutical DD, offering substantial benefits in efficiency, innovation, and scientific advancement for both research communities and the pharmaceutical industry.

nisarmpharm@gmail.com

In the current research, commercially available central venous catheters are coated with Curcumin using top coat and base coat dip coating technology. The objective behind the research was to examine the Biocompatibility, Hemocompatibility and Anti-biofilm Activity of Curcumin Coated Central Venous Catheters in the Prevention of CRBSI. The coated catheters were sterilized using Ethylene oxide sterilization. The residual Ethylene oxide content was determined as per ISO 10993-5 guidelines and found to be within the limits. The sterilized catheters were tested for sterility as per IP 2022 with successful results. This study aimed to assess the blood compatibility of Curcumin-coated CVC according to ISO 10993-4. We have evaluated the anti-biofilm Activity of Curcumin Coated Central Venous Catheters against S. aureus, P. aeruginosa, E. coli, K. Pneumonia, A. baumanii and C. albicans which are the main organisms responsible for CRBSI. Haemocompatibility studies like Haemolytic assay & viable cell count was performed. Cytotoxicity against the standard human cell line using MTT assay & Bioluminescence assay was performed. The biofilm inhibition and eradication was performed using Crystal Violet Assay, Ruthenium Red assay, Congo red method & Scanning Electron Microscopy. The polyurethane catheter coated with curcumin demonstrated good resistance to microbial colonization of the catheter surface. Due to a controlled release of Curcumin, the catheter performed well in cell toxicity and blood compatibility tests as well as anti-biofilm activity. The anticoagulant effect, biocompatibility and anti-biofilm activity could keep the functionality of CVC helping to prevent complications such as CRBSI.

## FORMULATION AND EVALUATION OF NANOPARTICLE-LOADED BUCCAL FILMS OF AMBRISENTAN FOR PULMONARY ARTERIAL HYPERTENSION

Prajapati Dashrath Bhalaram, Patel Khushi, Bhoomi S. Patel, Sachin Narkhede
Smt. B.N.B Swaminarayan Pharmacy College, Salvav – Vapi, India - 396191
dashrathvapi5@gmail.com

Pulmonary arterial hypertension is a progressive disease condition, with a high rate of illness and death. The patients require drug delivery solutions that are enough functionable to deliver better treatment. A drug called ambrisentan, which blocks endothelin receptors, for this ailment. But the liver grinds it down, and it dissolves in water, lessening the amount of the medicine that gets into the bloodstream. The purpose of this research was to develop and evaluate the buccal films containing Ambrisentan nanoparticles as a novel delivery system for the convenience to patients. Nanoparticles were prepared by solvent evaporation technique and added in mucoadhesive buccal films by solvent casting. The formulations were investigated for physicomechanical characteristic, surface pH, drug content spread, disintegration time and in vitro drug release behaviour. Furthermore, an ex vivo comparative study in pig buccal tissue was carried out to explore drug penetration and possible enhancement of drug bioavailability. The finished film dispensed quickly in less than 25 s adhered to mucosa strongly, and exhibited uniformity of drug content. It also demonstrated significantly improved release and absorption properties over conventional Ambrisentan tablets. Oral films, which are formulated with drug-loaded nanoparticles, may enhance drug dissolution, bypass hepatic metabolism, and reduce drug absorbed in the body system, based on these observations. This approach has the potential to offer improved patient compliance to PAH therapy and treatment results.

## METFORMIN CONJUGATED METALLIC NANOPARTICLE-BASED CHITOSAN SPONGE FOR CHRONIC WOUND HEALING APPLICATION

Beauty Behera, P. K. Sahoo and Shubham
Delhi Pharmaceutical Sciences and Research University, Pushp Vihar, New Delhi, India-110017
beauty.behera@dpsru.edu.in

Diabetic wounds need specialized attention and management especially due to underlying high glucose level and prolonged inflammation. The oral absorption of Metformin (MET) is compromised due to its low permeability resulting in poor bioavailability. Recent research highlights its use in reducing inflammation, supporting fibroblast proliferation, collagen synthesis, and blood vessel formation by topical administration. In the present study, we aimed to formulate MET conjugated silver nanoparticles (AgNP) sponge to enhance the cell proliferation and reepithelization of the diabetic wound. The MET-AgNPs were prepared by a green synthesis method by using the extracts of Ocimum tenuiflorum. Chitosan sponges of the conjugated MET-AgNP were obtained by pre-freezing at -20°C followed by lyophilization. The sponges were then characterized by UV visible, FTIR spectroscopy, particle size,

ISBN: 978-81-980623-8-3

Scanning electron microscope, swelling, in vitro and in vivo studies. A surface plasmon band at λmax 434 nm indicated the formation of drug conjugates of AgNP. The particle size and zeta potential of MET-AgNPs was found to be 92.32 nm and -11.5 ± 5.04 mV, respectively. The FTIR results showed a shift in the -OH stretching peak from 3277 $cm^{-1}$- 3315 $cm^{-1}$ in the polymeric MET-AgNP sponge. The SEM images displayed a porous structure with a pore size of 100-200 µm. The chitosan MET-AgNP sponges showed least swelling of about 65% at the end of 8 hours making it a suitable candidate for moist dressing. The in vivo studies showed improved efficacy of the MET-AgNP sponge with a wound contraction area of 3.33 ± 1.25 mm2 at the end of 14 days.

**Keywords**: Conjugates, metallic nanoparticles, Metformin, sponge, regeneration

**FORMULATION AND EVALUATION OF VIGNA MUNGO – BASED HERBAL SOAP FOR ANTIFUNGAL ACTIVITY**

Shanaz Banu*
College of Pharmaceutical Sciences, Dayananda Sagar University

Objective: This study aimed to formulate a herbal antifungal soap using Vigna mungo as a natural base and to incorporate selected medicinal plant extracts—Mangifera indica, Calendula officinalis, Acalypha indica, and Melaleuca alternifolia, to evaluate their combined antifungal efficacy. Methods: Extracts of the selected plants were prepared using Soxhlet and maceration methods. Two melt-and-pour soap bases—glycerine and shea butter—were used in combination with Vigna mungo paste to prepare eight formulations, including individual and combined extract blends. The formulations were evaluated for physico-chemical properties (pH, appearance, texture, weight variation, and foam height) and tested for in vitro antifungal activity against Candida albicans using the agar well diffusion method. Efinaconazole served as the standard control. Results: All formulations exhibited acceptable physicochemical properties. The formulations containing the combination of all extracts (G4 and S4) showed the highest zone of inhibition (22 mm and 23 mm respectively), indicating a synergistic antifungal effect. Among the bases, shea butter–based soaps demonstrated slightly better antifungal activity than glycerine-based ones. Conclusion: Herbal soap formulated with Vigna mungo base and selected antifungal plant extracts can serve as a safe and effective natural alternative to synthetic antifungal agents, particularly in topical applications for fungal skin infections caused by Candida albicans. The combination of multiple extracts enhances efficacy, and the choice of base influences the performance of the final product.

**Keywords**: Vigna mungo, Candida albicans, antifungal, Mangifera indica, Calendula officinalis, Acalypha indica, Melaleuca alternifolia

**GOLDEN HEALING: HARNESSING THE POWER OF PIPERINE AND CURCUMIN IN HYDROGEL PATCH FOR WOUND HEALING**

Mohammed Mohib Isani, Mr. Rajat Sayyed, Mr. Swapnil Dounde
Department of Pharmaceutics, MCE Society's Dr. PAIU Allana College of Pharmacy, Azam Campus, Pune, Maharashtra India 411001.

Wound healing is an ongoing clinical issue, prompting innovative strategies to ensure better outcomes. In this study, we investigate the potential of a hydrogel patch containing curcumin and piperine, two natural products celebrated for their anti-inflammatory and wound healing activities, respectively. The hydrogel patch presents an ideal vehicle for controlled release of these bioactive molecules, maximizing their therapeutic benefits. Curcumin, a polyphenol from turmeric, possesses an array of properties, including antioxidants, anti-inflammatory, and antimicrobial activities, which are essential for wound healing. Piperine, an alkaloid in black pepper, accelerates the bioavailability of curcumin and also possesses wound healing activities. Entrapment of these molecules in a hydrogel matrix assures controlled release kinetics, providing prolonged access of these molecules to the wound bed. This ensures a synergistic effect, improving tissue regeneration, angiogenesis, and collagen synthesis. Additionally, the hydrogel patch ensures protection to the wound surface from exterior pathogens, and infection risk is kept in check. The preclinical research shows increased wound closure, less inflammation, and increased tensile strength of the curcumin and piperine hydrogel patch as compared to standard dressings. Therefore, this new-age technique has great future potential in improving wound care therapy, providing an efficacious, cost-efficient, and safe modality to promote wound healing.

**FORMULATION AND EVALUATION OF TRANSDERMAL PATCHES OF GLIPIZIDE**

Veliventi Naga Sahithi* D.N.S.Sravani
Department of pharmaceutics, Vikas institute of pharmaceutical sciences, Near Airport, Rajahmundry, East Godavari District, Andhra Pradesh, India -533102.
nagasahithiveliventi@gmail.com

Glipizide, a widely used oral hypoglycemic agent, suffers from low bioavailability due to extensive firstpass metabolism and a short half-life. Transdermal drug delivery offers a promising alternative by providing controlled release, improved patient compliance, and bypassing hepatic metabolism. The present study aimed to formulate and evaluate transdermal patches of Glipizide using polymers such as Hydroxypropyl Methylcellulose (HPMC) and Ethyl Cellulose (EC) in different ratios. Patches were prepared by the solvent casting method and evaluated for thickness, weight uniformity, surface pH, moisture content, drug content, folding endurance, and in vitro drug release. The results indicated uniform patches with satisfactory mechanical strength and controlled drug release over 24 hours. In vitro studies demonstrated sustained release following Higuchi kinetics, suggesting diffusion-controlled release. The optimized formulation exhibited good adhesion, stability, and the potential to maintain therapeutic plasma levels, indicating that transdermal delivery of Glipizide could be a viable strategy to enhance its therapeutic efficacy and patient compliance.

**FORMULATION, EVALUATION, AND AI-ASSISTED OPTIMIZATION OF A BLUE PEA EXTRACT SERUM**

Fardeen A. Ansari

The increasing demand for sustainable and plant-based cosmetic formulations has led to growing interest in the use of Clitoria ternatea (Blue Pea) flower extract, known for its antioxidant and anti-aging potential. This study explores the formulation and evaluation of a Blue Pea–based face serum through a comprehensive approach, beginning with extraction and phytochemical characterization. Advanced computational tools and AI-driven predictive modeling were integrated to optimize extract concentration, excipient compatibility, and stability parameters. The serum was evaluated for physicochemical properties such as pH, spreadability, viscosity, and washability, alongside stability and non-irritancy assessments. AI-supported analysis enabled efficient prediction of formulation behavior, shelf-life, and consumer safety, thereby reducing trial-and-error in formulation design. The results demonstrate that Blue Pea extract can be effectively utilized in serum formulations with promising cosmetic and therapeutic applications, while AI integration enhances the precision, efficiency, and scalability of natural skincare product development.

**FORMULATION AND EVALUATION OF LOW DENSITY FLOATING DRUG DELIVERY SYSTEMS OF MEBEVERINE HYDROCHLORIDE**

Sailaja*, G.Chandra Sekhara Rao
Vignan Institute of Pharmaceutical Technology (A), Duvvada, Visakhapatnam-530049
ksailukeerthi3@gmail.com

Dosage forms with a prolonged gastric residence time and sustained release are called as Gastroretentive drug delivery systems. Low density systems is one of the pharmaceutical approaches in this area. Mebeverine hydrochloride is intended to be used in conditions like functional abdominal pain in children. The aim of the current study is to prepare as well as to evaluate oil-entrapped floating microspheres of Mebeverine hydrochloride to favorably improve the gastric residence nature of the drug in the stomach. The micro-spheres were formulated by ionotropic-gelation method using mahuva oil and various polymers like hydroxy propyl methyl cellulose and sodium starch glycolate of varying concentrations. A total of twelve formulations were developed

ISBN: 978-81-980623-8-3

in the laboratory. The developed micro-spheres were evaluated for floating properties, flow property and drug entrapment efficiency. The shape and surface morphology were evaluated using optical microscopy. The micro-spheres were also subjected to in-vitro drug release studies. In the case of formulation F9 the drug release was extended upto 12 hours and floating of micro-spheres remained for more than 12 hrs. Mahuva oil was found to be a suitable low density material in the formulation of floating micro-spheres.

**Keywords**: Functional abdominal pain, Mebeverine, hydroxy propyl methyl cellulose, Mahuva oil, floating micro-spheres.

**FORMULATION AND DEVLOPMENT OF BRAIN TARGETED NANO PREPARATIONS FOR NEURODEGENERATIVE DISEASES**

Nikita J. Bhute1, Dr Amol A. Tatode1, Dr Milind J. Umekar1
1 Department of pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India.

In the present study, a potential lipid material compound L was designed and synthesized, which possesses bi-functional properties, that is, the lipophilic steroid for inserting into the liposomal membrane in addition to the hydrophilic glucose residue outside the membrane for GLUT1 recognition. The objective of this study was to formulate Agmatine sulphate loaded liposomes, which was made with Phospholipid and glucose-cholesterol derivatives (compound L) to get high affinity for GLUT-1 receptors present on BBB. The liposomes were prepared by using Film Dispersion method. A two-factor three-level (32) factorial design was used to optimize the formulation. Nine formulation batches (A1-A9) were prepared. Two factors as independent variables (X1-amount of Phospholipid and X2-amount of glucose-cholesterol derivative i.e., Compound L) were taken with three levels (+1, 0, -1). The levels of two factors were selected on the basis of preliminary experiments conducted and their effect on two dependent variables (% Entrapment Efficiency and Particle Size) was studied along with their % relative error. Formulation A4 was selected by the Design-Expert software which exhibited % EE (94.67±3.67%), and PS (459±1.21 nm). API and excipients were evaluated for Preformulation studies (colour, odour, nature, m.p., solubility, UV, HPLC, FTIR etc.) and the Liposomes were evaluated by comparative study of Batch F1 (2:1:0), Batch F2 (2:0:1) [i.e., optimized Batch A4] and Batch F3 (2:0.5:0.5) (vesicle digital morphology, particle size, zeta potential, % Entrapment Efficiency, % Drug content, % in vitro diffusion study and stability studies). The optimized batch was further used for FESEM and in vivo studies (Blood and body organ distribution studies). After i.v administration, increased time spent in platform quadrant and number of entries in platform quadrant during probe trial of Batch F2/A4 (2:0:1) [i.e., optimized Batch A4] than Batch F1 (2:1:0), Batch F3 (2:0.5:0.5) and Agmatine (10 mg/kg) as compared to control group in STZ induced Alzheimer's model was evaluated. The biodistribution data showed higher brain concentration of Batch F2 (2:0:1) [i.e., optimized Batch A4] than those of standard Agmatine sulphate (10 mg/ kg) after i.v administration. Thus, i.v administration of Agmatine sulphate loaded Liposomes may be appropriate and preferred as a valuable Brain-targeted drug delivery system for the treatment of Alzheimer's disease.

**ELECTRONIC MEDICATION MONITORING DEVICES: RETHINKING PATIENT-CENTERED MEDICATION ADHERENCE**

Damavarapu Chandana
Department of pharmacy practice , Ratnam Institute of pharmacy, SPSR Nellore – 524346, Andhra pradesh.
Chandanadamavarapu870@gmail.com

Medication non-adherence continues to undermine the effectiveness of even the most sophisticated therapies. Despite many advances in pharmaceutical care, non-adherence is a persistent obstacle, rendering optimal outcomes frustratingly elusive. Addressing this demands interventions that are not only strong and evidence-based but centered around the patient experience. Enter Electronic Medication Monitoring Devices (EMMDs): an emerging class of technologies bringing real-time clarity to regimen management. EMMDs—think intelligent pillboxes, digitally linked blister packs, and ingestible sensors—move beyond conventional reminders. They generate objective adherence data, flag missed doses, and deliver actionable insights for providers. Instead of relying on self-reports or assumptions, healthcare professionals gain measurable evidence, driving opportunities for individualized interventions and genuinely collaborative care models.Yet the promise of EMMDs does not come without caveats. Challenges—including cost barriers, patient comfort with technology, digital literacy gaps, and important data privacy considerations—are especially significant across diverse healthcare environments such as those found in India. Ultimately, EMMDs represent more than technical progress. They have the potential to reframe medication adherence as a shared, verifiable responsibility between patients and the healthcare system. By supporting transparency, accountability, and more responsive care, these devices may signal a meaningful evolution for modern, patient-centered healthcare.

Colorectal cancer remains one of the most prevalent forms of cancer across the wide, requiring the development of efficient, biocompatible, and targeted drug delivery systems. In this work, we aim to design and assess the polymeric nanoparticles as carriers computationally for delivery of a key chemotherapeutic used in colon cancer treatment i.e. Paclitaxel. In order to form the nanoparticle we will use amphiphilic copolymers, poly (D, L-lactide)-poly (ethylene glycol) (PDLLA-PEG) and poly (lactic-co-glycolic acid)-poly (ethylene glycol) (PLGA-PEG). They were selected to assess drug–polymer interaction and compatibility. Initial all-atom molecular dynamics simulations followed by MM/GBSA free energy calculations were performed to study the binding affinities, interaction patterns, and stability of polymer–drug complexes. This is followed by coarse-grained MARTINI simulations to perform self-assembly of polymer–drug systems into nanoparticles. The resulting nanoparticles were characterized through clustering analysis, radius of gyration (Rg), solvent-accessible surface area (SASA), including eccentricity, to predict shape and for size, the ratio of hydrodynamic radius, and Rg is calculated. Encapsulation efficiency was calculated from drug distribution within polymeric cores. Furthermore, machine learning models are being developed to predict physicochemical and biological properties, such as zeta potential, molecular release kinetics, and nanoparticle-induced toxicity profiles. Together, this integrated computational approach provides a framework for the design of polymeric nanocarriers and lays the foundation for developing optimized formulations of Paclitaxel for colorectal cancer therapy.

**FORMULATION AND EVALUATION OF BIOACTIVE RITHA HERBAL SOAP USING THE DECOCTION METHOD WITH SELECTED MEDICINAL PLANTS**

Mr .I. RISHI KANTH , Dr. Atla Srinivasa Rao, and Mrs. G. Nangalya swathi Department of Pharmaceutical Analysis,
Shri Vishnu College Of Pharmacy-534202
swathi.g@svcp.edu.in

The aim of this study was to develop and evaluate Ritha herbal soap formulated with bioactive herbal extracts recognized for their ethnopharmacological and dermatological properties in Ayurveda. The formulation incorporated extracts from Sapindus mukorossi, Acacia nilotica, Aloe barbadensis, Curcuma longa, Cocus nucifera, Azadirachta indica, Ocimum sanctum, and Citrus lemon. These plant materials were processed using appropriate extraction techniques tailored to their specific constituents. The soap was prepared by combining the extracts with fatty oils and sodium hydroxide (lye) using the hot decoction

ISBN: 978-81-980623-8-3

method. The prepared herbal soap was compared to commercially available soaps in terms of its physical and chemical properties, including appearance, color, and odour. Key parameters of the prepared soap were measured, yielding the following results: pH (8.38), % free alkali content (0.34), foamability (17 cm), foam stability (15 cm), moisture content (6.4%), and alcohol-insoluble matter (2.25%). Additionally, antioxidant and antibacterial activities were assessed, demonstrating that the soap exhibited potent antioxidant and antibacterial properties. The study concludes that high-quality herbal soap can be effectively formulated using the hot decoction method, incorporating parameters such as skin compatibility and the bioactive potential of the selected herbs. This approach offers significant promise for the herbal cosmetics industry by addressing limitations associated with existing polyherbal or chemical-based formulations, thus paving the way for safer and more efficacious dermatological products.

**SMART POLYMER-COATED MICRONEEDLE TECHNOLOGY FOR CONTROLLED 5-FLUOROURACIL DELIVERY.**

Anbarasu Murugan*[1], Kamal Karunanithi[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4].
[1234]Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai, Tamil Nadu.

Melanoma remains one of the fastest-growing skin cancers, and conventional 5-fluorouracil therapy is restricted by limited skin penetration and adverse local reactions. To address these challenges, polymer-coated polymeric microneedles were developed as a novel intradermal delivery approach. The microneedle arrays were fabricated using a polymeric core of PVP K30 loaded with 5-fluorouracil, followed by coating with a thin layer of Eudragit E100 through dip-and-spin technique. The coating served as a semipermeable barrier to control drug release and to improve the mechanical strength required for reliable skin insertion. Comparative evaluation of coated and uncoated microneedles demonstrated enhanced strength in the coated system and a sustained release pattern as opposed to the rapid release observed from uncoated arrays. Ex vivo skin permeation studies confirmed prolonged delivery from the coated arrays, while stability assessments indicated consistent drug retention and reproducible release profiles during storage. The combined outcomes suggest that polymer-coated microneedles can successfully overcome the shortcomings of conventional topical 5-fluorouracil by enabling controlled release into the dermal layers, improving drug permeation, and minimizing surface-level irritation. This platform represents a minimally invasive and patient-friendly alternative for the management of melanoma and highlights the potential of polymeric microneedles as an advanced drug delivery technology in oncology.

The present research focus on the formulation and optimization of mucoadhesive buccal tablets for the management of xerostomia, employing the direct compression technique. The selected drug enhances salivary secretion and alleviates dry mouth symptoms. Tablets were designed using varying levels of polymers along with MCC, mannitol, and magnesium stearate as excipients. A $3^2$ full factorial design was implemented to investigate the influence of formulation variables on mucoadhesive strength, residence time, disintegration, and in-vitro drug release. Compatibility of drug and excipients was confirmed by FTIR and DSC analyses, while evaluation studies demonstrated satisfactory physicochemical characteristics. The optimized formulation exhibited high mucoadhesive strength (15.1 ± 0.13 g/cm²), sustained adhesion time, and 97.7 ± 1.1% drug release within 120 minutes. Surface pH and swelling index studies supported buccal compatibility and effective hydration. Optimization through Design-Expert® software yielded a desirability score of 0.888, with predicted and observed responses showing <±1% relative error, confirming the model's reliability. Overlay and desirability plots identified Carbopol 934P (12.5 mg) and SSG (10 mg) as optimal concentrations for achieving desired performance. Overall, the developed system represents a promising buccal drug delivery platform for the sustained and effective treatment of xerostomia.

**Keywords**: Xerostomia, Carbopol 934P, SSG, 32 full factorial design, mucoadhesive.

The unique properties—such as biocompatibility, biodegradability, bio-absorbability, low cost, easy fabrication, and high versatility—have made polycaprolactone (PCL) the center of attraction for researchers. The derived introduction in this manuscript gives a pretty detailed overview of PCL, so you can first brush up on it. Discussion on the various PCL-based derivatives involves, but is not limited to, poly(ε-caprolactone-co-lactide) (PCL-co-LA), PCL-g-PEG, PCL-g-PMMA, PCL-g-chitosan, PCL-b-PEO, and PCL-g-PU specific properties and their probable applications in biomedicine. This paper has considered examining the differences in the diverse disease subtypes and the therapeutic value of using PCL. Advanced strategies for PCL in delivery systems are also considered. In addition, this review discusses recently patented products to provide a snapshot of recent updates in this field. Furthermore, the text probes into recent advances in PCL-based DDS, for example, nanoparticles, liposomes, hydrogels, and microparticles, while giving special attention to comparing the esters in the delivery of bioactive compounds such as anticancer drugs. Finally, we review future perspectives fine-tuning mechanical strength/degradation rate, biocompatibility, and long-term effects in living systems.on using PCL in biomedical applications and the hurdles of PCL-based drug delivery, including

The present study aimed to develop and optimize felodipine orodispersible tablets (ODTs) using various concentrations of superdisintegrants to enhance dissolution rate and improve patient compliance. A $3^2$ full factorial design was employed to study the influence of croscarmellose sodium (4–8% w/w) and microcrystalline cellulose (20–40% w/w) on disintegration time and in-vitro drug release. Preformulation studies, including organoleptic evaluation, solubility determination, melting point analysis, FTIR, and DSC, confirmed the purity of the drug and its compatibility with excipients. The prepared powder blends showed excellent micromeritic properties, enabling direct compression. All formulations met pharmacopoeial requirements, exhibiting uniform weight, adequate hardness, low friability (<1%), and rapid disintegration. The optimized batch (F5) disintegrated in 24.3 seconds and achieved 99.5% drug release within 15 minutes. Stability studies conducted for six months under ICH-recommended conditions indicated no significant changes in physical appearance, drug content, or dissolution profile. These findings suggest that the optimized ODT formulation can serve as a stable, patient-friendly dosage form with potential for enhanced antihypertensive therapy.

**DEVELOPMENT OF NEBIVOLOL HCL-LOADED OLAMINOSOMES INCORPORATED INTO 3D PRINTED MICROARRAY-BASED TRANSDERMAL PATCHES FOR THE TREATMENT OF HYPERTENSION**

Dwarakanadha Reddy Peram
Department of Pharmaceutics, Annamacharya College of Pharmacy (Autonomous), Rajampet -516126, Andhra Pradesh, India
dwarakanadhareddyperam@gmail.com

The current study aimed to develop and evaluate Nebivolol Hydrochloride (HCl)-loaded olaminosomes incorporated into 3D-printed microarray-based transdermal patches for effective management of hypertension. Olaminosomes were formulated using oleic acid and oleylamine via the thin film hydration method and subsequently embedded into matrix-type transdermal patches prepared using a combination of Eudragit RS100 and HPMC K100M polymers. Advanced 3D Digital Light Processing (DLP) technology was utilized for microarray patch fabrication. The developed patches were evaluated for physicochemical properties, In-vitro drug release, and stability. Among all formulations, F5 (HPMC: ERS100 – 100 mg: 900 mg) demonstrated optimal physical characteristics, highest drug content (98±4.42%), and maximum in-vitro release (97±3.94% at 30 minutes). SEM confirmed uniform drug distribution, and ATR-FTIR studies confirmed the absence of interactions between drug and excipients. Stability studies under ICH conditions indicated no significant changes over 3 months. The findings support the potential of 3D-printed microarray patches as a novel transdermal drug delivery system for Nebivolol.

**Keywords**: Nebivolol Hydrochloride, Olaminosomes, Transdermal Patch, 3D Printing, Controlled Release.

**FORMULATION AND EVALUATION OF VALSARTAN FAST DISINTEGRATING TABLETS**

Puli Sai Raja Rajeswari*, Suripeddi Muralidhar
Department of Pharmaceutics, Vikas Institute of Pharmaceutical Sciences, Nidagtla near airport, Rajahmundry, East Godavari district, Andhra Pradesh, India 533102

Fast disintegrating tablets (FDTs) have gained importance as they rapidly disintegrate or dissolve in the oral cavity without the need for water, thus improving patient compliance. Valsartan, an angiotensin II receptor blocker widely prescribed for hypertension and has poor aqueous solubility, limiting its oral bioavailability. The present investigation aimed to develop FDTs of Valsartan with enhanced solubility and rapid disintegration. Solid dispersions of Valsartan were prepared using mannitol as a carrier by the kneading method to improve solubility and dissolution characteristics. Among the prepared solid dispersions, Valsartan: Mannitol in the ratio of 1:4 exhibited superior solubility enhancement and was selected for FDT formulations. Various concentrations of superdisintegrants, including sodium starch glycolate(SSG) and crospovidone(CP), were incorporated to optimize tablet disintegration. The formulations were prepared by direct compression and evaluated for pre-compression and post-compression parameters. UV spectrophotometry was employed for assay and in vitro dissolution studies. Among all formulations, F7 containing 6% crospovidone demonstrated the shortest disintegration time and significantly improved dissolution rate compared to others. FT-IR and DSC studies confirmed the absence of drug–excipient interactions. The optimized FDT of Valsartan thus presents a promising approach to enhance dissolution and patient acceptability in antihypertensive therapy.

**Keywords**: Valsartan, Solid dispersions, Kneading method, Superdisintegrants, Fast disintegrating tablets.

Vandanakadari43@gmail.com

Nocturnal asthma is a distinct subtype of asthma phenomena where symptoms intensify at night, impacting nearly three-quarters of all asthmatics. This condition's exacerbation at a specific time of day poses a need for novel treatments that synchronize medication delivery with biological rhythms. Theophylline, a bronchodilator of the methyl xanthine class, while effective poses a challenge because of its conventional oral dosage form's narrow therapeutic window, gastrointestinal adverse effects, and poor compliance. This thorough research aims to the controlled release theophylline patch for nocturnal asthma providing insights into the scientific justification, formulation and manufacturing concerns, clinical uses, and regulatory framework for transdermal controlled release patches of theophylline. This research incorporates the state-of-the-art concerns on matrix polymers, permeation enhancement polymers, safety, Chrono table medication, and future avenues of digital health integration and patent landscape post expiration.

**Keywords**: transdermal patch, theophylline, nocturnal asthma, controlled release, chronotherapy.

A. N Maheswara Reddy*, P. V V Siva Krishna, P. Srinivasa Babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

The primary objective of this study is to design and formulate a bilayered floating tablet comprising Glipizide and Metformin hydrochloride, employing fenugreek mucilage to serve dual roles as a super disintegrant and release retardant. This innovative approach aims to enhance the effectiveness of diabetes mellitus treatment. The compatibility of Glipizide, Metformin hydrochloride, and Fenugreek mucilage was confirmed through IR spectral studies. Various bilayered floating tablets were developed, with Glipizide incorporated into the immediate release layer utilizing modified Trigonella as a super disintegrant. The sustained release layer contained Metformin hydrochloride, with Trigonella gum acting as a release rate retardant, using the direct compression method. The physical evaluation of the bilayered floating tablets, encompassing parameters such as weight variation, friability, hardness, swelling index, and drug content, yielded satisfactory results. The release pattern of all formulations adhered to zero-order kinetics, corroborating the Peppas mechanism. Notably, the release profile from fenugreek as a release rate retardant exhibited predominant non-Fickian diffusion ($p>0.5$). Among the formulations, F5 contains an optimized concentration of natural excipient emerged & showed 93.04% Glipizide drug release after 25 minutes and 97.44% Metformin hydrochloride release over 12 hours. Importantly, individual layer assessment in the floating bilayered tablet revealed no significant adverse impact of Metformin hydrochloride on Glipizide, ensuring therapeutic levels to combat elevated blood sugar without inducing toxic effects. In vivo radiographic imaging of rabbit abdomens administered with the selected formulation exhibited a floating lag time of 10 minutes, and a total floating time greater than 10 hours. In conclusion, the development of floating bilayered anti-diabetic tablets incorporating Trigonella Foenum as a key excipient exhibit promising potential for controlled drug release. The bi-layered structure ensures sustained therapeutic effects, while Trigonella Foenum contributes to enhanced drug stability and anti-diabetic properties.

**Keywords**: Floating Bilayered Tablet, Trigonella Foenum, Anti-diabetic, Glipizide, Metformin.

**THEME: PHARMACEUTICAL TECHNOLOGY**

**DESIGN AND DEVELOPMENT OF BIFONAZOLE-LOADED NANOSPONGES FOR TOPICAL DRUG DELIVERY**

Ch. Vinay Babu*, P. V V Siva Krishna, P. Srinivasa Babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

This research endeavor focuses on the development of sustained-release Bifonazole-loaded nanosponges incorporated topical gel with improved permeability and stability of Bifonazole. Nanosponges were crafted by cross-linking with β-Cyclodextrin to develop porous nanosized structures. The drug was integrated using a solvent evaporation method, employing solvents such as ethanol, acetone, and chloroform. The choice of solvent during the drug loading process significantly influenced the encapsulation efficiency of the nanosponges. The encapsulation

ISBN: 978-81-980623-8-3

efficiency of the drug-loaded nanosponge was increased with crosslinking ratios. The formulation with a 1:1 ratio of β-Cyclodextrin: crosslinking agent, chloroform as the solvent, and Carbopol as the gelling agent showed better results based on drug encapsulation efficiency, drug content, and sustained release characteristics. The drug release from all the formulations exhibited zero-order release kinetics, and the mechanism of drug release followed the Peppas model. The diffusion exponential coefficient (n) values, ranging from 0.9402 to 1.1864, indicated a non-fickian diffusion mechanism. The optimized Bifonazole-loaded nanosponge gel offered sustained topical delivery with improved solubility, permeability, and stability. In conclusion, the design and development of bifonazole-loaded nanosponges present a promising approach for enhancing topical drug delivery. The nanosponge formulation offers advantages such as improved stability, controlled release, and enhanced skin penetration. These characteristics contribute to the potential efficacy and safety of bifonazole in treating various dermatological conditions.

**Keywords**: Bifonazole, Nanosponge, Topical Drug Delivery, β-Cyclodextrin.

## FORMULATION AND EVALUATION OF COLON TARGETED DRUG DELIVERY SYSTEMS.

Pedde kusumanjali * Ch.Sandhya Rani
Department of pharmaceutics, Vikas institute of Pharmaceutical Sciences, Near Air Port, Rajahmundry, East Godavary District, Andhra Pradesh, India-533102.
peddesailu400@gmail.com

The present study ained to develop and evaluate colon-targeted drug delivery systems of Nitrofurantoin using guar gum as a natural polysaccharide carrier. Matrix tablets were formulated by wet granulation method with starch paste as a binder, incorporating varying proportions of guar gum. In-vitro drug release studies were conducted at 37 ± 0.5 'C under sequential conditions simulating gastrointestinal transit:0.1 N HCl (2 h), phosphate buffer pH 7.4 (3 h), and simulated colonic fluid pH 6.8 containing 4% w/v rat caecal content (10 h). Results revealed that the formulation containing 20% guar gum (F4) released only 10.04% of Nitrofurantoin in the upper gastrointestinal conditions, compared to 20-30% drug release from other formulations. In simulated colonic fluid, F4 exhibitednearly complete drug release (~100%). These findings indicate that guar gum- based matrix tablets, particularly with 20%concentration, are cffective in minimizing premature release and achieving site-specific delivery of Nitrofurantoin to the colon, offering potential therapeutic benefits in colonic infections.

**Keywords**: Colon targeted drug delivery, Nitrofurantoin, Guar gum, Matrix tablets, Wet granulation, Rat caecal content, In-vitro release.

## NANO-EMULSION APPROACH TO ENHANCE SKIN HYDRATION FORMULATION AND EVALUATION OF A HYALURONIC ACID MOISTURIZING CREAM

M.Nagaraju1, Abhinaya2, Vaishnavi3, Maloth Ravi4, Dr. B Rajkumar5*
Department of Pharmaceutics, Moonray Institute of Pharmaceutical Sciences, Raikal, Shadnagar, N.H-44 Ranga Reddy-509202 Telangana, India.

The present study focuses on the formulation and evaluation of a nanoemulsion-based moisturizing cream containing hyaluronic acid, a naturally occurring biopolymer known for its excellent water retention and skin hydration properties. Nanoemulsion systems offer enhanced stability, improved drug penetration, and a non-greasy aesthetic compared to conventional emulsions, making them highly suitable for topical cosmetic applications. The nanoemulsion was prepared using an oil-in-water (O/W) system, employing suitable oils, surfactants (such as Tween 80), and co-surfactants to achieve droplet sizes in the nanometer range. Hyaluronic acid was incorporated as the active moisturizing agent due to its biocompatibility and hygroscopic nature. The formulation was converted into a cream base by adding a suitable thickener to improve viscosity and application properties. The prepared nanoemulsion cream was evaluated for various parameters, including physical appearance, pH, viscosity, spreadability, droplet size, zeta potential, drug content, and in vitro drug release. The formulation showed desirable pH (5.1 to 6.7), smooth texture, and nano-sized droplets (103–110 nm), with sustained drug release up to 8 hours. No signs of phase separation or degradation were observed during stability studies. The results indicate that the nanoemulsion-based cream is a stable, effective, and cosmetically acceptable formulation for prolonged skin hydration. It holds significant potential for commercial cosmetic and dermatological applications in moisturizing and anti-aging products.

**Keywords**: Hyaluronic acid, oil, surfactants, Co-surfactants, Nanoemulsion, Moisturizing
cream, In vitro drug release studies

## "DEVELOPMENT AND EVALUATION OF ANTIHYPERTENSIVE MOUTH-DISSOLVING TABLETS USING NOVEL CO-PROCESSED EXCIPIENTS"

Shubhangi S. Mali*, Dr. Manoj. M. Nitalikar
Rajarambapu College of Pharmacy, Kasegaon Tal: Walwa Dist: Sangli

Hypertension requires immediate attention and therapy. The drug should get immediately disintegrated, dissolved and absorbed. Therefore, it is necessary to provide dosage regime which will anticipate effect.[1] Co-processing involves combining two or more excipients to create a single entity that exhibits superior functionality compared to the individual components. For preparation of co-processed excipients starches like barley starch, maize starch, Xylitol starch etc. can be used. Incorporating this natural starch into co-processed excipients blends can enhance critical tablet properties such as flowability, compressibility, and disintegration time. This is particularly beneficial in the formulation of MDTs, where rapid disintegration is essential for quick onset of action and improved bioavailability. This research aims to develop a co-processed excipients blend using barley starch to formulate MDTs for antihypertensive drugs, addressing the challenges of rapid disintegration, taste masking, mechanical strength, moisture sensitivity, and poor API solubility. The outcome of this study could provide a novel approach to enhance patient compliance and therapeutic efficacy in the management of hypertension. [4] This research is significant as it explores the potential of barley starch, a natural and biocompatible excipient, in enhancing the formulation of MDTs for antihypertensive drugs. The findings could lead to the development of more patient-friendly dosage forms, ultimately improving therapeutic outcomes and patient adherence to treatment regimens.

## DEVELOPMENT AND EVALUATION OF A DNA-APTAMER-BASED NANOPARTICLE TARGETING HER2 BIOMARKERS IN BREAST CANCER: FORMULATION, CHARACTERIZATION, AND IN VITRO EVALUATION

G. Vamsi Surendra, P. Raman Kumar, P. Srinivasa babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Guntur, India

Particularly breast cancer, poses significant therapeutic challenges due to tumor challenges in targeted drug delivery contributing to treatment inefficacy and systemic toxicity. This study introduces a novel biomarker-targeted polymeric nanoparticle (NP)formulation for doxorubicin (DOX) delivery, specifically designed to exploit HER2 overexpression in breast cancer cells. The NPs were prepared using a modified nanoprecipitation method, incorporating poly (lactic-co-glycolic acid) (PLGA) as the polymer matrix and anti-HER2 antibodies for surface functionalization to enable active targeting. In vitro evaluation included physicochemical characterization, drug release kinetics, cellular uptake studies, and cytotoxicity assays on HER2-positive (SK-BR-3) and HER2-negative (MDA-MB-231) cell lines. In vivo assessments were conducted in xenograft mouse models to evaluate biodistribution, antitumor efficacy, and toxicity. Results demonstrated that the targeted NPs exhibited a mean particle size of 150 nm, encapsulation efficiency of 85%, and sustained DOX release over 72 hours. Enhanced cellular uptake and cytotoxicity were observed in HER2-positive cells, with a 2.5-fold reduction in IC50 compared to free DOX. In vivo, the formulation achieved 60% tumor volume reduction with minimal cardiotoxicity. These findings suggest that biomarker-targeted NPs offer a promising platform for precision oncology, improving therapeutic outcomes while mitigating off-target effects. This interdisciplinary approach from pharmaceutics and oncology highlights the potential for clinical translation in targeted cancer therapy.

**NATURAL MACROMOLECULES POLYSACCHARIDE-BASED DRUG DELIVERY SYSTEMS TARGETING TUMOR NECROSIS FACTOR ALPHA RECEPTOR FOR THE TREATMENT OF CANCER**

Khushi Rani1,2#, Mohammad Adnan Raza1,2, Ajazuddin1,2
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023

Cancer is one of the most significant abnormalities in medical sciences for which a new and efficient therapeutic intervention is desired. Targeting the tumor necrosis factor-alpha receptor appears to have a critical role in both cancer development and immune modality. In this review, an attempt is made to review the potential and av enues of natural macromolecules that have augmented drug delivery systems for specific targeting of the tumor necrosis factor-alpha receptor in cancer therapy. Biological macromolecules, derived from biocompatible and biodegradable sources such as lipids, polysaccharides of natural origin, such as chitosan, hyaluronic acid, algi nate, pectin, dextran, starch, cellulose, agar, carrageenan, guar gum, chondroitin sulfate, pullulan, and konjac glucomannan, have been immensely utilized in drug delivery systems for its negligible toxicity mucoadhesive properties, ability to enhance drug stability, and controlled release capabilities. Various novel drug delivery approaches are discussed in detail, including those using polysaccharides, lipids, chitosan, proteins, polymers, dendrimers, exosomes, hydrogels, albumin nanoparticles, silk nanoparticles, and cyclodextrin nanoparticles, incorporating cutting-edge engineering techniques for encapsulation of chemotherapeutic, immunomodulatory, and gene-silencing drugs for site-specific delivery at a site of a tumor. Such macromolecules can mitigate toxicity and even bypass multidrug resistance through their intrinsic property, ligand functionalization for targetability towards receptors. In the present review, an attempt is made to present an outlook for the role of natural macromolecules is being a breakthrough intervention in interfering with tumor necrosis factor-alpha receptor- dependent processes in cancer and a new direction in developing efficient, non-toxic, and personalized therapies for anti-cancer activities.

**"STATIN AND CYP3A4 INHIBITOR INTERACTION LEADING TO RHABDOMYOLYSIS IN HYPERLIPIDEMIC PATIENTS"- A CASE STUDY**

R.Bhagawathi*, K. Kavyasudha M.Pharm
1. Pursuing Pharm-D at Ratnam Institute of Pharmacy, SPSR Nellore, Andhra Pradesh, India
2.Department of Pharmacology, Associate Professor in Ratnam Institute of Pharmacy, Nellore, Andhra Pradesh, India

Statins, widely prescribed for hyperlipidemia and cardiovascular disease, are generally well-tolerated but can cause severe adverse effects when combined with CYP3A4 inhibitors (Clarithromycin / Ketoconazole) such as clarithromycin or ketoconazole. This case study investigated the effects of co-administration of statins (atorvastatin or simvastatin) with CYP3A4 inhibitors in 25 patients aged 40–65 years over a 3-month period. Serum creatine kinase (CK) levels, liver function, and renal parameters, as well as clinical signs of muscle toxicity, were closely monitored in each patient. During the study period, several patients developed symptoms including muscle pain, weakness, and dark urine. Laboratory assessments revealed significantly elevated CK levels, consistent with rhabdomyolysis, in a subset of patients. The interaction is primarily due to inhibition of CYP3A4, which reduces statin metabolism and causes accumulation and an increased risk of myotoxicity. Management included immediate discontinuation of the offending CYP3A4 inhibitor, temporary suspension or dose reduction of the statin, aggressive hydration, and supportive care to prevent renal complications. Up until normalization, CK and renal function were closely monitored. This case series highlights the critical importance of vigilant monitoring when prescribing statins alongside CYP3A4 inhibitors, particularly in middle-aged and older adults. Preventing serious outcomes, such as acute renal failure, requires prompt intervention, prompt recognition of myopathy symptoms, and awareness of potential drug–drug interactions.

**Keywords**: Statins, CYP3A4 inhibitors, Rhabdomyolysis, Hyperlipidemia, Drug–Drug Interaction, Creatine Kinase

**ENHANCED DISSOLUTION AND CONTROLLED RELEASE OF MEFANAMIC ACID THROUGH β-CYCLODEXTRIN NANOSPONGES: A QBD BASED STUDY**

Tambe Shraddha Aravind, Rathod Pravin, Dr. Manisha Karpe
Bharati Vidyapeeth's College Of Pharmacy, Sector 8, Cbd Belapur, Navi Mumbai-400614

Mefenamic acid (MFA), a nonsteroidal anti-inflammatory drug (NSAID), exhibits potent analgesic and anti-inflammatory effects but is limited by poor aqueous solubility and low oral bioavailability, resulting in variable therapeutic efficacy and gastrointestinal adverse effects. To overcome these challenges, β-cyclodextrin (β-CD)–based nanosponges were developed as a novel carrier system for MFA. Blank nanosponges were synthesized via the melt method using diphenyl carbonate as a crosslinker and optimized employing a Central Composite Design (CCD). MFA was subsequently loaded into the optimized nanosponges through a freeze-drying technique. The formulations were characterized for physicochemical and structural properties using Fourier-transform infrared spectroscopy (FTIR), differential scanning calorimetry (DSC), powder X-ray diffraction (PXRD), transmission electron microscopy (TEM), particle size analysis, and zeta potential measurement. The optimized MFA-loaded nanosponges exhibited spherical morphology, nanoscale particle size, high entrapment efficiency, and enhanced amorphous dispersion of the drug. In vitro dissolution studies demonstrated markedly improved solubility and a sustained drug release profile extending up to 12 hours, with release kinetics following a first-order model. The optimized formulation was successfully encapsulated into hard gelatin capsules, which complied with all pharmacopoeial quality standards. Accelerated stability studies confirmed the formulation's robustness with no significant changes in drug content, particle size, or release characteristics. These findings highlight β-CD nanosponges as a promising strategy to enhance the solubility, stability, and controlled release of poorly water-soluble drugs such as MFA.

**Keywords**: Mefenamic acid, β-cyclodextrin, nanosponges, solubility enhancement, sustained release, Central Composite Design, freeze-drying, oral drug delivery.

**TAILORING MULTIFUNCTIONAL NANOCUBOSOME TOPICAL SPRAYS FOR INTEGRATED SUNSCREEN, ANTI-AGING, AND MOISTURIZING EFFECTS**

I. Prathima, N. Santhi Priya, P. Srinivasa babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

Modern cosmeceutical development emphasizes multifunctional systems capable of simultaneously providing photoprotection, anti-aging, and hydration. Conventional topical products often suffer from poor stability, limited penetration, and lack of sustained effects. Nanocubosomes, owing to their bicontinuous lipid–water architecture and high encapsulation capacity, offer a promising platform to overcome these challenges. The present study focused on tailoring multifunctional nanocubosome sprays designed to integrate sunscreen, anti-aging, and moisturizing effects within a single formulation. Nanocubosomes were prepared using glycerol monooleate and Poloxamer F127 via high-shear homogenization and loaded with UV filters (avobenzone, titanium dioxide nanoparticles), antioxidants (α-tocopheryl acetate, resveratrol), and moisturizers (hyaluronic acid, ceramides). The formulations were evaluated for particle size, polydispersity index, zeta potential, entrapment efficiency, spray characteristics, and stability. Functional assessments included in vitro UV absorption, antioxidant potential (DPPH assay), skin hydration (TEWL and corneometry), and ex vivo dermal permeation. Optimized sprays displayed a particle size below 200 nm with narrow distribution (PDI <0.25) and high entrapment of both hydrophilic and lipophilic actives. The multifunctional nanocubosomes exhibited broad-spectrum UVA/UVB absorption (SPF ~40), 2.5-fold

ISBN: 978-81-980623-8-3

higher antioxidant activity compared with free actives, and a 45% reduction in transepidermal water loss indicating improved hydration. Ex vivo permeation studies confirmed enhanced dermal deposition of antioxidants and moisturizers relative to conventional emulsions. Tailored nanocubosome sprays successfully combined photoprotection, anti-aging, and moisturization in one platform. These multifunctional formulations highlight the potential of nanocubosomes as next-generation cosmeceuticals for advanced skin protection and rejuvenation.

**Keywords**: Nanocubosomes, Multifunctional spray, Sunscreen, Anti-aging, Moisturizing.

**PC-763**

## DESIGN AND CHARACTERIZATION OF SPANLASTIC NANOCARRIERS FOR STABILITY ENHANCEMENT AND DERMAL PENETRATION OF VITAMIN E DERIVATIVES

L. Reshma naga vyshnavi, N. Santhi Priya, P. Srinivasa babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

α-Tocopheryl acetate (TA), a stable esterified derivative of Vitamin E, is widely recognized for its antioxidant and photoprotective properties. However, its clinical efficacy is limited by poor penetration through the stratum corneum. The present study aimed to formulate and evaluate α-Tocopheryl acetate–loaded spanlastics as a novel nanocarrier system to improve stability, dermal penetration, and topical delivery. TA-loaded spanlastics were prepared by the ethanol injection method using Span 60 and Tween 80 in varying ratios. The formulations were characterized for entrapment efficiency (EE%), particle size (PS), polydispersity index (PDI), zeta potential, deformability index (DI), and in vitro release profile. The optimized formulation was further assessed for ex vivo skin permeation and deposition using excised rat skin compared with a plain TA solution. The optimized TA-spanlastic formulation demonstrated high EE% (~85% w/w), nanoscale particle size (<200 nm, PDI < 0.3), and excellent deformability (DI ~10). A sustained release profile was observed, with significant enhancement in skin permeation and dermal deposition compared to the plain drug solution. Stability testing confirmed good physical and chemical stability of the formulation for up to 6 months. α-Tocopheryl acetate–loaded spanlastics enhanced topical stability, controlled release, and dermal penetration of Vitamin E acetate. This nanocarrier system shows strong potential as a cosmeceutical formulation for protecting skin against oxidative stress and UV-induced photodamage.

**Keywords**: α-Tocopheryl acetate, Vitamin E derivative, spanlastics, topical delivery, skin permeation, photoprotection, stability.

## OPTIMIZATION OF OPHTHALMIC NANOFORMULATION OF PIROXICAM USING QBD APPROACH

Yashpal More, Avish Maru
Department of Pharmaceutics, SNJB's ShrimanSureshdada Jain College of Pharmacy, Chandwad, Nashik, Maharashtra, India – 423101.
yasshmore000@gmail.com

In the current research, ophthalmic nanoformulation of Piroxicam was prepared and optimized by Quality by Design (QbD). The objective behind the research was to formulate nanoparticles based eye drop and to evaluate them for various parameters like particle size, zeta potential, entrapment efficiency, assay, percentage yield and drug release and sterility testing. The nanoparticles were prepared by emulsion solvent diffusion method using 32 factorial design. Speed of rotation (RPM) and ethyl cellulose concentration are having impact on particle size of nanoparticles and entrapment efficiency. It was found that as the speed of rotation increases, the particle size of nanoparticles gets decreased and as the concentration of ethyl cellulose increased particle size of nanoparticles was found to be decreased. As the speed of rotation increases the entrapment efficiency of nanoparticles get increased and as the concentration of ethyl cellulose increases entrapment efficiency of nanoparticles also get increases.On the basis of data obtained from evaluation of batches as well as factorial design model study, batch B3 was selected as optimized batch which was having low particle size and good entrapment efficiency.

**Keywords**: Piroxicam, ophthalmic nanoformulation, quality by design, eye drop, ethyl cellulose.

**PC-765**

## DESIGN AND EVALUATION OF IRBESARTAN FAST DISSOLVING TABLETS BY USING JACK FRUIT SEED STARCH AS NATURAL SUPERDISINTEGRANT

K. Kavya Venkata Peddi Ratnam, Dr.T. Balakrishna
Department of Pharmaceutics, V.V. Institute of Pharmaceutical Sciences, Seshadri Rao Knowledge village, Gudlavalleru -521356, Andhra Pradesh, India.

In the present investigation an attempt was made to isolate starch from jack fruit seed powder and utilizing the same as excipient to design of fast dissolving tablets Irbesartan. Starch was isolated from jack fruit seeds by aqueous and alkali extraction process. The physicochemical and phytochemical tests confirmed the presence of only carbohydrates and polysaccharides in the extracts. Acute toxicity studies for the extract indicated that all the rats were healthy with no physiological changes in their behavior. The fast-dissolving tablets were prepared by wet granulation technique by using isopropyl alcohol as granulating fluid. All the tablet formulations were found to be stable and meeting I.P specified limits for post compression parameters. In vitro dissolution studies were carried out in 0.1N HCl by using USP apparatus II (paddle method). The dissolution rate of formulations F5 and F8 containing 5%w/w of alkali extracted starch and 5 % w/w of croscaramellose sodium showed faster disintegration and improved dissolution rate than compared to marketed and other formulations. Majority of the formulations displayed first order release kinetics and were found to be linear with R2 values in the range of 0.946-0.993. FTIR and DSC analysis revealed that there were no major interactions between the drug and the excipients used in the tablets. SEM analysis was done to study the surface morphological characteristics of starch extract and drug which indicated that there were no physical and chemical interactions during tabletting process. Accelerated stability studies indicated that the formulations were stable.

**Keywords**: Irbesartan, fast dissolving tablets, Jack fruit seed starch, Croscarmellose sodium.

## FORMULATION AND EVALUATION OF ANTI-ULCER HERBAL GEL FROM CLUSTER FIG (FICUS RACEMOSA)

Ayesha Sayyed 1*, Swapnil Dounde 1, Zeba shaikh 1
1 MCES'S Dr P.A Inamdar University Allana College of Pharmacy Pune
syyd.ayesha2003@gmail.com

Cluster fig (Ficus racemosa), a plant known for its wide array of medicinal benefits, has shown promising potential in the treatment of mouth ulcers. The bioactive compounds found in its fruits, leaves, and bark, including flavonoids, tannins, and phenolic compounds, contribute to its therapeutic properties. Research suggests that Ficus racemosa possesses anti-inflammatory, antimicrobial, and antioxidant effects, which play a significant role in alleviating mouth ulcers. The plant's ability to reduce inflammation and promote tissue healing helps in accelerating the recovery of the mucosal lining in the oral cavity. Additionally, its antimicrobial properties help combat secondary infections that may exacerbate ulcer conditions. These findings support the potential use of Ficus racemosa as a natural remedy for preventing and managing mouth ulcers, although further clinical trials are needed to confirm its effectiveness and determine optimal usage. This study concludes that the Cluster fig anti-ulcer gel presents a promising natural alternative for ulcer management, offering enhanced bioavailability, patient compliance, and reduced adverse effects compared to conventional therapies.

**Keywords**: Cluster fig (Ficus racemosa), Mouth ulcers, Tannins, Phenolic compounds, Anti-inflammatory.

**DESIGN AND DEVELOPMENT OF DUAL EUDRAGIT BASED POLYMERIC MICROSPHERES FOR CONTROLLED DRUG DELIVERY OF MEBEVERINE HCL**

S. Siva Prasad and S.Vidyadhara
Department of Pharmaceutics, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences, Chowdavaram, Guntur-522019.India.
sivasunkara123@gmail.com

In the current study, formulation and evaluation of Mebeverine Hydrochloride microspheres are done through a mixture of Eudragit L100 and Eudragit RS100 polymers, by the solvent evaporation technique. The microspheres were prepared by giving different ratios of the drug to polymer; 1:1 to 1:5, to determine the influence of the concentration of the polymer on the drug entrapment, release characteristics and the physical characteristics of the microspheres. Eudragit L100 is pH-sensitive, which facilitates release in intestinal environments, whereas RS100 remains released by its pH-independent permeable shell. The commendation of 1:1 (L100:RS100) ratio of the 1: 3 (drug:polymer) proportion seemed to exhibit the finest results in terms of entrapment efficiency, controlled drug release, and stability of microsphere. An example of a long term pharmacological intervention is the Irritable Bowel Syndrome (IBS) which is a chronic gastrointestinal disorder characterized by abdominal pain, changes of bowel habits, and a visceral hypersensitivity. FTIR of the optimized formulation showed that there was no interaction between the polymers and the drug and thus it was stable. Differential Scanning Calorimetry (DSC) showed encapsulation of the drug by change in melting endotherm. In-vitro release experiments showed that the 1:1 drug to polymer ratio emitted the 97% of drug which increases to persistent but incomplete release by higher ratios (1:4 and 1:5) owing to increased matrix density. In this way, the dual Eudragit system offers a pH-responsive, synergistic delivery of Mebeverine HCl, with high opportunities in the IBS management.

**Keywords**: Mebeverine HCl, Eudragit L100, Eudragit RS100, Microspheres.

**DEVELOPMENT OF TICAGRELOR SOLID DISPERSIONS USING ENTADA SCANDENS SEED STARCH BY MODIFIED SOLVENT EVAPORATION METHOD**

Suryadevara Vidyadhara and Doppalapudi Sandeep
Department of Pharmaceutics, Chebrolu Hanumaiah Institute of Pharmaceutical Sciences, Chandramoulipuram, Chowdavaram, Guntur, Andhra Pradesh, India – 522019.
svidyadhara@gmail.com

The current research aims to enhance the bioavailability of Ticagrelor, a BCS class 4 drug, by using Entada scandens seed starch as a superdisintegrant. Ticagrelor is an agent that is indicated for prevention of stroke and heart attack. Starches from plants are used as binders, diluents, disintegrants, and lubricants. Starches were extracted from Entada scandens seed powder using the alkali method (sodium hydroxide at 0.1%, 0.25%, and 0.5% concentrations) and distilled water. The starch prepared from 0.5% sodium hydroxide (ESS4) showed the best physicochemical properties. Solid dispersions were prepared using ticagrelor, Croscarmellose sodium, and starch in various concentrations using solvent evaporation and modified solvent evaporation techniques. In vitro dissolution studies showed that the solid dispersion formulation TF10 containing ticagrelor and Entada scandens seed starch in a 1:5 ratio along with 15% w/w of alkali extracted starch showed faster disintegration and an enhanced dissolution rate than the solid dispersions prepared alone with Croscarmellose sodium. FTIR and DSC studies revealed no major interactions between the drug and excipients. X-Ray Diffraction and SEM studies revealed the crystalline and amorphous nature of the formulations. The study concluded that Entada scandens seed starch possesses superdisintegrant properties, indicating its usage in preparation of novel fast disintegrating formulations.

**Keywords**: Entada scandens, Solid dispersions, Ticagrelor, Croscarmellose sodium, modified solvent evaporation method.

**MCC ADSORBED SOLID SOLUTIONS OF EZETIMIBE FOR ENHANCED BIOAVAILABILITY**

Grandhi Srikar, Akhtar Shakil
Department of Pharmaceutical Science, Vignan's Foundation for Science Technology and Research, Guntur-522213, Andhra Pradesh, India
srikar.grandhi@gmail.com

The objective of this study is to prepare solid solutions of ezetimibe (EZT) followed by developing into orodispersible tablets (ODTs) to enhance the oral bioavailability. Solid solutions were prepared by fusion technique. Influences of three different formulation parameters viz. type of carrier, amount of carrier and amount of adsorbent on the solubility and dissolution rate of EZT from the solid solutions was investigated through design of experiments. Optimization of these formulation factors was done by desirability functions approach using Design Expert software. The ODTs from the optimized solid solutions were prepared by direct compression. Compatibility of EZT with the selected excipients was established by infrared spectroscopy. Solid solutions were characterized by differential scanning calorimetry, micromeritic analysis, solubility analysis & dissolution studies. The solubility and dissolution rate of solid solutions were found to be significantly ($p < 0.05$) influenced by selected formulation factors. Optimized solid solutions exhibited a solubility of 1.53 mg/mL against the solubility of pure EZT of 0.1 mg/mL. The best formulation of the ODTs exhibited a disintegration time of 18 sec. and 98% of drug dissolved within 10 min. These results demonstrated that solubility and dissolution of EZT can be enhanced by formulating it in the form of amorphous solid solutions followed by ODTs. These improved characteristics could help in enhancing oral bioavailability of EZT.

**Keywords**: Ezetimibe, Solid solutions, Fusion technique, Orodispersible tablets, Bioavailability

Shampoos are among the most widely used cosmetic preparations for cleaning and maintaining scalp and hair health. While synthetic shampoos are effective, their chemical ingredients and preservatives may cause irritation and long-term side effects. To address these concerns, the present study focused on the formulation and evaluation of a polyherbal shampoo using extracts of Psidium guajava, Phyllanthus emblica, Hibiscus rosa-sinensis, Sapindus mukorossi, and Aloe barbadensis. These herbs were selected for their well-established cleansing, conditioning, antioxidant, and antifungal properties. The extracts were combined with natural additives including gum tragacanth, tea tree oil, lemon juice, glycerin, and lavender oil to produce herbal shampoo. The prepared shampoos were evaluated through a series of physicochemical and performance parameters. Tests included pH determination, percentage of solid content, viscosity measurements, foam stability, cleansing action, dirt dispersion, and antifungal activity. The results confirmed that the formulations maintained an acidic pH within the optimal range for scalp health, possessed acceptable solid content, and stable foaming ability. The cleansing action was satisfactory, with the shampoos effectively

ISBN: 978-81-980623-8-3

removing grease and dirt without leaving residues. Dirt dispersion tests indicated that impurities remained in the water than in the foam, ensuring better rinsing properties. The antifungal studies by agar well diffusion method demonstrated inhibition of fungal growth, confirming the potential of the formulation to manage dandruff and related scalp conditions. Overall, the study highlights that polyherbal shampoos can provide an effective, safe, and eco-friendly alternative to synthetic products by combining cleansing and therapeutic benefits, promise hair and scalp hygiene, nourishment and protection.

**Keywords**: Polyherbal shampoo, Psidium guajava, Phyllanthus emblica, Antifungal activity, scalp health.

**FORMULATION AND IN VITRO CHARACTERIZATION OF FLEXOSOMES FOR OCULAR DRUG DELIVERY SYSTEMS**

Lavanya Somarajua, Dwarakanadha Reddy Peramb
Department of Pharmaceutics
a Lecturer, Government Polytechnic for Women Kadapa-516002, AP, India, Research Scholar, Jawaharlal Nehru Technology University Anantapur, AP, India.
b Professor, Annamacharya College of Pharmacy, Rajampet– 516126, AP, India.
slavanya556@gmail.com

Flexosomes, a novel class of flexible, edge-activated liposomes, have emerged as promising nanocarriers for ocular drug delivery due to their enhanced deformability and ability to penetrate the corneal barrier. This study presents the formulation and comprehensive in vitro characterization of drug-free flexosomes intended for ocular applications. Flexosomes were prepared using the ethanol injection method by optimizing key formulation variables, including phospholipid concentration, type and amount of edge activators, and hydration volume. The resulting vesicles exhibited a nanosized particle distribution (approximately 150–250 nm) with a narrow polydispersity index, indicating uniform size. Zeta potential measurements revealed sufficient surface charge (±30 mV) for colloidal stability. Transmission electron microscopy confirmed spherical morphology with intact vesicular structure. The deformability of the vesicles was demonstrated through extrusion assays, highlighting their enhanced flexibility compared to conventional liposomes. Stability studies over 30 days showed minimal changes in size and zeta potential, indicating good physical stability. These findings suggest that drug-free flexosomes possess desirable physicochemical properties, making them suitable candidates as ocular drug delivery vehicles for subsequent drug loading and therapeutic applications.

**Keywords**: Flexosomes, drug loading, Zeta potential, Ocular DDS

**DESIGN AND DEVELOPMENT OF NOVEL BILAYERED MUCOADHESIVE PATCH OF ENALAPRIL MALEATE**

Subhasish Sahoo, Tejaswini Mohanty, Madhulika Yadav, Sujata Mohapatra
Department of Pharmaceutics, School of Pharmaceutical Sciences, Siksha 'O' Anusandhan University, Bhubaneswar, Odisha, India- 751003
subhupvt@gmail.com

Hypertension, being a recurring medical condition, needs convenient and effective treatment. In the present study, we focused on designing a new bilayered mucoadhesive patch of enalapril maleate for the management of hypertension. The bilayered film consist of one drug loaded mucoadhesive layer of hydroxypropyl methylcellulose K100 and other backing membrane layer of ethyl cellulose to facilitate sustained drug release pattern. Three different formulations (F1-F3) designed by solvent casting technique were evaluated for their mucoadhesive properties, drug release characteristics, and mechanical strength. The patches were also characterized physicochemical in terms of their thickness, weight, and surface morphology. The mucoadhesion time for drug delivery patch F1 containing hydroxypropyl methylcellulose K100 achieved about 150 minutes with a maximum value, thus securing prolonged residence at the site of application for the drug. The drug exhibited sustained release from patch F1 over 7 hours with the release rate depending upon the polymer employed. The optimized patch possessed suitable mechanical strength, flexibility, and adhesive characteristics. In summary, it is concluded that the developed novel bilayered mucoadhesive patch of Enalapril maleate illustrates a viable strategy and promising approach for the management of hypertension.

**Keywords**: Enalapril maleate, bilayered patch, mucoadhesion, hypertension

**BUCCAL MUCOADHESIVE TABLETS OF DOMPERIDONE MALEATE: A FORMULATION APPROACH**

Samrudhi Babhulkar, Pravin Suruse and Vinod Thakare
Nagpur College of Pharmacy, Nagpur, Maharashtra, India-441110.
samrudhibabhulkar87@gmail.com

The present study aimed to develop and evaluate a mucoadhesive dosage form of Domperidone maleate, a synthetic benzimidazole compound that acts as a dopamine D2 receptor antagonist with antiemetic activity. Mucoadhesive tablets were prepared using the direct compression method. Among all formulation batches, F3 (containing Carbopol 940 and sodium alginate) demonstrated the best performance, exhibiting a consistent drug release over 7 hours with an extent of 94.44%. Graphical analysis of F3 using Higuchi's model indicated that drug release was diffusion-mediated. In vitro permeability studies of F3 over 7 hours showed 76.69% drug release. FTIR analysis confirmed the absence of any interaction between the drug and polymers.

**Keywords**: Domperidone maleate, Mucoadhesive tablet, antiemetic

**PC-775**

**DEVELOPMENT AND CHARACTERIZATION OF NOVEL PRASUGREL-LOADED NANOSPONGE FORMULATIONS**

Mukesh P. Ratnaparkhi, Atul N. Suryawanshi*
Marathwada Mitra Mandal's College of Pharmacy, Thergaon (Kalewadi), Pune 411033, Maharashtra, India

The present study aimed to develop and characterize Prasugrel-loaded nanosponges to enhance solubility, encapsulation efficiency, and stability of the drug, thereby improving its potential bioavailability. Four different formulations (F1–F4) of nanosponges were prepared using varying proportions of β-cyclodextrin and ethyl cellulose, with dichloromethane serving as the cross-linking agent. The formulations were evaluated for drug loading efficiency, particle size distribution, polydispersity index (PDI), surface morphology (SEM), drug-polymer interaction (FTIR), and physical state (DSC and XRD analyses). Formulation F4 exhibited the highest drug loading efficiency (39.74%) due to an optimal polymer-to-drug ratio and controlled cross-linking, whereas F2 showed the lowest efficiency (16.87%) due to excessive cross-linking hindering drug entrapment. Particle size analysis revealed F4 had the smallest and most uniform particles (267.9 nm; PDI 0.263), indicating superior nanosponge formation. SEM analysis confirmed smooth, spherical nanosponges with evenly distributed pores in F3. FTIR spectra validated successful drug encapsulation through evident molecular interactions. DSC and XRD analyses showed a complete transition of Prasugrel from crystalline to amorphous form in F4, suggesting improved solubility and encapsulation efficiency compared to other batches. The optimized formulation F4 demonstrated effective encapsulation, enhanced solubility, and stable nanosponge characteristics, making it a promising nanocarrier system for the delivery of poorly water-soluble drugs like Prasugrel. This study underscores the potential of nanosponges in enabling sustained and controlled release of hydrophobic drugs.

**FORMULATION AND EVALUATION OF HERBAL MOUTH DISSOLVING FILM OF TULSI EXTRACT**

Ashutosh Chourasiya1,2#, Mohammad Adnan Raza1,2*
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023

Mouth dissolving films (MDFs) have emerged as an advanced dosage form that provides rapid disintegration, improved patient compliance, and convenience of administration without the need for water. In the present work, an attempt has been made to formulate and evaluate a

ISBN: 978-81-980623-8-3

herbal mouth dissolving film of Tulsi (Ocimum sanctum) extract, a well-known medicinal plant possessing antimicrobial, antioxidant, and immunomodulatory properties. The films were prepared by solvent casting method using polyvinyl alcohol (PVA) as a film-forming polymer and glycerol as a plasticizer. Different concentrations of Tulsi extract were incorporated into the polymeric solution to optimize drug loading. The prepared films were evaluated for various physicochemical parameters such as thickness, folding endurance, surface pH, drug content uniformity, disintegration time, and in vitro dissolution profile. Preliminary results indicated that the films were uniform, flexible, and transparent with satisfactory mechanical strength. The disintegration time was found to be within 30–45 seconds, ensuring quick release of the active phytoconstituents. In vitro dissolution studies revealed more than 85% release of active constituents within 10 minutes, confirming the suitability of the formulation for rapid therapeutic action.

The study concludes that herbal mouth dissolving films of Tulsi extract can serve as a promising alternative dosage form for rapid relief in oral infections and as a natural immunomodulatory supplement.

**Keywords**: Mouth dissolving film, Tulsi extract, Ocimum sanctum, herbal formulation, solvent casting method.

**PC-777**

## FORMULATION AND IN-VITRO CHARACTERIZATION OF ABACAVIR SULPHATE EFFERVESCENT FLOATING TABLETS

M.Harish*, Aravinda Nalla, Krishna Mohan Chinnala
School of Pharmacy, Department of Pharmaceutics, Nalla Narasimha Reddy Education
Society's Group of Institutions, Hyderabad, Telangana, India.

After oral administration of Abacavir, rapid absorption occurs from upper part of gastro intestinal tract with peak concentrations occurring at 0.63 - 1 hr after dosing.Conventional drug therapy with tablets produce relatively rapid and high peak blood levels that requires frequent administration to maintain effective range of plasma drug levels. Thisconventional therapy leads to reduced effectiveness with poor therapeutic management. To overcome the inadequacy of conventional therapy with tablets, floating sustained release.Abacavir tablets were developed. Floating sustained release Abacavir Sulphate tablets were prepared by using direct compression method. Tablet were formulated using Ethyl Cellulose with hydrocolloids like Hydroxypropyl Methylcellulose (HPMC K4M) and Carbopol 974P as release retarding polymers, Sodium bicarbonate (NaHCO3) and Citric acid as effervescent agents. Tablets were then evaluated for various physical parameters including hardness, thickness, weight variation, friability, drug content, in-vitro buoyancy, Swelling index and In-vitro gastro retentive drug release were conducted. Drug and excipient compatibility studies show that they are compatible with each other. The optimized formulation (F9) shows the hardness of 5.7kg/cm2, tablet thickness of 2.74mm, 0.45% of friability, in-vitro buoyancy was up to 6 hours and % drug release was 90.56% in 6 hours. Drug release kinetics was found to follow non-fickian diffusion.Hence, F9 is considered as optimizedformulation based on in-vitro buoyancy and % drug release.

**Keywords**: Abacavir sulphate; Carbopol 974P; HPMC K4M; Ethyl cellulose; Effervescent floating tablets.

**PC-778**

## DEVELOPMENT OF NANOEMULGEL OF 5-FLUOROURACIL FOR SKIN MELANOMA USING GLYCYRRHIZIN AS A PENETRATION ENHANCER

Aadya Mishra1,2#, Nimish Gupta2, Dilpreet Singh2*
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023

The purpose of this study was to enhance the topical delivery of 5-Fluorouracil (5-FU), a cancer treatment, by developing a nanoemulgel formulation. Glycyrrhizin (GLY), a natural penetration enhancer has been investigated to exhibit synergistic effects with 5-FU in inhibiting melanoma cell proliferation and inducing apoptosis, Hence, GLY, along with suitable lipids was utilized to create an optimized nanoemulsion (NE) based gel. Solubility studies and ternary phase diagram revealed isopropyl myristate (IPM), Span 80, Tween 80 as S and Transcutol P as co-surfactant. IPM demonstrates excellent solubilizing properties facilitates higher drug loading, ensuring efficient delivery to the target site.,The optimized formulation consisting of 40 % IPM, 30 % of mixture of Tween80: Span80 (S mix mix ) and 15 % Transcutol P provides with a nanometric size of 64.1 ± 5.13 nm and drug loading of 97.3 ± 5.83 %. The optimized formulation observed with no creaming and breakeing of NE and found thermodynamically stable during different stress conditions (temperatures of 4.0 ◦ thawing ( 21.0 ± 0.50 ◦ C to 20.0 ± 0.50 ◦ C and 45.0 ◦ C) and physical C). The NE was then transformed into a nanoemulgel (NEG) using 1.5 % w/w Carbopol base and 0.1 % w/w glycyrrhizin. The ex vivo permeability studies showed significant en hancements in drug permeability with the GLY-based 5-FU-NEG formulation compared to pure 5-FU gel in excised pig skin upto1440 min in PBS 7.4 as receptor media. The IC 50 values for Plain 5-FU gel, 5-FU-NEG, and GLY-based 5-FU-NEG were found to be 20 µg/mL, 1.1 µg/mL, and 0.1 µg/mL, respectively in B16F10 cell lines. The percentage intracellular uptake of GLY-5-FU-NEG and 5-FU-NEG was found to be 44.3 % and 53.6 %, respectively. GLY-based 5-FU-NEG formulation showed alterations in cell cycle distribution, in compared to 5- FU-NE gel. The overall findings suggest that the GLY-based 5-FU-NEG holds promise for improving anti- melanoma activity.

## ULTRASONICALLY ASSISTED ANTISOLVENT PRECIPITATION OF FELBAMATE NANOSUSPENSIONS: A FORMULATION & EVALUATION STUDY

V Jhansipriya Marabathuni and Naidu Narapusetty
Bellamkonda Institute of Technology and Science, Podili, Andhrapradesh, India – 523245.
Jhansi.priya356@gmail.com

The Felbamate nanosuspension formulation was prepared by using the anti-solvent precipitation and ultrasonic method. In this work the polymers like HPMC K4M, Poloxamer 188.Polyvinyl alcohol, Polyethylene Glycol 400, as anti-solvent acetone was used. Total eight formulations were prepared by using different composition of the polymers based on the prepared formulations (F1 – F8) were evaluated for Drug content, Solubility determination, In vitro drug release study, ATR-FTIR spectroscopy, Particle size determination and poly dispersity index, and Morphology characterization by scanning electron microscopy. All the formulations were evaluated for drug content which was in the range 90.15 & to 98.95 %. The solubility determination of all formulations in phosphate buffer pH 6.8 was found to be in the range of 0.0156 mg/ml to 0.0375 mg/ml. The results showed that the solubility of formulation was found to be higher in F1 (0.031 mg/ml) compared with other formulations. The solubility of all formulations improved (from insoluble to slightly soluble) compared to pure drug of Felbamate. The in vitro release was carried out for all formulations. The results showed that as the concentration of polymer was increased, the percentage drug release was decreased. Optimized formulations showed 98.69% and 96.49% drug release within 120 minutes, but pure drug released upto 22.46% only. The release rate kinetic data for the best as a F1 formulation showed that the formulation provided good linearity was observed with the zero order (R2 = 0.9), the zero-order kinetics explains the good release of the prepared nanosuspension over the period of 120 minutes. The data were fitted into the Korsmeyer-Peppas equation which showed good linearity and the slope of the Korsmeyer-Peppas plot (n= 0.969) were found to be more than 0.45 indicating the diffusion mechanism is Case II transport.

## GASTRO-RETENTIVE FLOATING BILAYER TABLETS: A NOVEL APPROACH FOR CO-DELIVERY OF METFORMIN HYDROCHLORIDE AND OLMESARTAN USING DESIGN OF EXPERIMENTS

C. Revanth*, P. Srinivasa Babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

The study aimed to develop gastro-retentive floating bilayer tablets for the co-delivery of Metformin Hydrochloride and Olmesartan using a Design of Experiments (DoE) approach. Metformin was formulated as an extended-release (ER) layer, while Olmesartan constituted the immediate-release (IR) layer. The ER layer contained Hydroxypropyl

ISBN: 978-81-980623-8-3

Methylcellulose (HPMC K100) as the polymer and sodium bicarbonate ($NaHCO_3$) as the gas-generating agent, prepared via wet granulation. The IR layer used crospovidone as a superdisintegrant and $NaHCO_3$ for gas generation, also formulated by wet granulation. The tablets were evaluated for physical and chemical parameters, floating characteristics, drug release, and stability. All formulated tablets passed standard quality control tests. Upon incorporation of the gas-generating agent, the floating lag time was reduced to 3-5 minutes, with a floating duration of over 10 hours. Drug release from the ER layer sustained beyond 8 hours, with Metformin exhibiting zero-order release kinetics, following the Korsmeyer-Peppas model with a super case II transport mechanism. Stability studies over the designated period indicated no significant changes in physical appearance, physicochemical properties, or drug release profiles. The developed bilayer floating tablets demonstrated effective co-delivery of Metformin and Olmesartan with desirable floating and sustained release characteristics, making them a promising strategy for improving therapeutic outcomes in managing conditions like hypertension and diabetes. This study also highlights the importance of a systematic approach to formulation optimization and the evaluation of the dissolution profile.

**Keywords**: Gastro-retentive floating bilayer tablets, Metformin Hydrochloride, Olmesartan, Extended-release (ER), Immediate-release (IR), Design of Experiments (DoE).

## NANOCRYSTALLIZATION OF LANSOPRAZOLE FOR SOLUBILITY ENHANCEMENT USING A DUAL POLYMER STRATEGY

Durdana Farheen and Balakrishna
Department of Pharmaceutical sciences, V.V.Institute of pharmaceutical sciences, Andhra Pradesh, India-521356.
durdanafarheen7@gmail.com

This study aims to improve the aqueous solubility and acid stability of lansoprazole, a proton pump inhibitor with poor oral bioavailability due to low solubility and acid sensitivity. Lansoprazole nanocrystals were prepared using the antisolvent precipitation method. The drug was dissolved in ethanol and injected into an aqueous phase containing a stabilizer under high-speed homogenization. Two hydrophilic polymers—polyvinyl pyrrolidone (PVP) and polyvinyl alcohol (PVA)—were tested as stabilizers at drug-to-polymer ratios of 1:1, 1:2, and 1:3. The resulting nanocrystals were characterized for particle size, dissolution behavior, and physicochemical properties using FTIR and DSC analyses. Among all formulations, the PVP-based nanocrystals at a 1:3 ratio showed the best performance, demonstrating smaller and more uniform particles, enhanced dissolution within one hour, and superior physical stability with minimal agglomeration. FTIR results confirmed no chemical interaction between drug and polymer, while DSC analysis indicated partial amorphization, supporting successful nanocrystal formation. Compared to PVA, PVP proved more effective in stabilizing the formulation and improving drug solubility. These results indicate that PVP at a 1:3 ratio is the optimal stabilizer for preparing lansoprazole nanocrystals by the antisolvent method, with potential to significantly enhance the drug's oral bioavailability.

**Keywords**: Lansoprazole, Nanocrystals, Polyvinylpyrrolidone, Polyvinyl alcohol, Antisolvent precipitation.

**PC-782**

## DESIGN AND DEVELOPMENT OF BIFONAZOLE-LOADED NANOSPONGES FOR TOPICAL DRUG DELIVERY

Ch. Vinay Babu*, P. V V Siva Krishna, P. Srinivasa Babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.

This research endeavor focuses on the development of sustained-release Bifonazole-loaded nanosponges incorporated topical gel with improved permeability and stability of Bifonazole. Nanosponges were crafted by cross-linking with β-Cyclodextrin to develop porous nanosized structures. The drug was integrated using a solvent evaporation method, employing solvents such as ethanol, acetone, and chloroform. The choice of solvent during the drug loading process significantly influenced the encapsulation efficiency of the nanosponges. The encapsulation efficiency of the drug-loaded nanosponge was increased with crosslinking ratios. The formulation with a 1:1 ratio of β-Cyclodextrin: crosslinking agent, chloroform as the solvent, and Carbopol as the gelling agent showed better results based on drug encapsulation efficiency, drug content, and sustained release characteristics. The drug release from all the formulations exhibited zero-order release kinetics, and the mechanism of drug release followed the Peppas model. The diffusion exponential coefficient (n) values, ranging from 0.9402 to 1.1864, indicated a non-fickian diffusion mechanism. The optimized Bifonazole-loaded nanosponge gel offered sustained topical delivery with improved solubility, permeability, and stability. In conclusion, the design and development of bifonazole-loaded nanosponges present a promising approach for enhancing topical drug delivery. The nanosponge formulation offers advantages such as improved stability, controlled release, and enhanced skin penetration. These characteristics contribute to the potential efficacy and safety of bifonazole in treating various dermatological conditions.

**Keywords**: Bifonazole, Nanosponge, Topical Drug Delivery, β-Cyclodextrin.

**PC-783**

## TAMOXIFEN CITRATE-LOADED LIQUID CRYSTALLINE NANOCARRIERS FOR BREAST CANCER TREATMENT: EXPERIMENTAL AND COMPUTATIONAL APPROACH

Likhitha U, Usha Y Nayak
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education, Manipal 576104, Karnataka, India
usha.nayak@manipal.edu

Tamoxifen citrate (TMX), a key therapy for estrogen-receptor-positive breast cancer, suffers from poor solubility, rapid clearance, and systemic toxicity. Advanced drug delivery systems can overcome these issues by enabling targeted delivery, sustained release, and reduced side effects. Loading TMX onto nanocarriers allows safer, more effective treatment of solid tumors, maximizing therapeutic benefit while minimizing toxicity. In the present study, a TMX-encapsulated liquid crystalline nanoparticle was prepared, exhibiting a particle size of 162.3 ± 8.78 nm, a polydispersity index of 0.23 ± 0.03, and a drug encapsulation efficiency of 98.5%. The presence of glycerol monooleate and poloxamer 407 enhanced the drug entrapment by creating a lipid bilayer matrix that holds lipophilic drugs like TMX. Robust intermolecular interactions between TMX and excipients were captured by molecular dynamics simulations using Schrodinger's materials science suite. FTIR, DSC, FE-SEM, and HR-TEM provided detailed insight into the nanoscale morphology and internal ordering of the mesophases. In vitro drug release (at pH 5.5 and 7.4) studies demonstrated a sustained release profile. An in vivo toxicity study was carried out using the genetic model Drosophila melanogaster, confirming that nanoformulation was non-toxic, without influencing survival and motor defects in flies. This study combines computational simulations, nanostructure engineering, and biosafety profiling, demonstrating the quantitative framework for improved delivery of poorly soluble therapeutics.

**Keywords**: Tamoxifen, drug delivery system, liquid crystals, molecular dynamics.

**PC-784**

## QUALITY BY DESIGN (QBD) BASED FORMULATION AND CHARACTERIZATION OF ACARBOSE'S OSMOTIC CONTROLLED RELEASE TABLETS

B. Venkata Lakshmi*, P. Srinivasa Babu
Department of Pharmaceutics, Vignan Pharmacy College, Vadlamudi, Affiliated to JNTU, Kakinada, Andhra Pradesh – 522213, India.
bathulavenkatalakshmi09@gmail.com

The purpose of the study was to develop and optimize controlled porosity osmotic tablets of acarbose using a Quality by Design (QbD) approach. The aim was to overcome limitations of conventional acarbose formulations, such as short half-life, poor bioavailability, and multiple dosing, by designing a sustained release system that could improve therapeutic efficacy, patient compliance, and clinical outcomes in type II diabetes management. Acarbose was identified and characterized by melting point determination, FTIR, and HPLC assay. Granules were prepared by wet granulation and evaluated for pre-compression parameters, including angle of repose, bulk density, tapped density, Carr's index, and Hausner's ratio. A $3^2$ full factorial design was employed using concentration of mannitol and microcrystalline cellulose

ISBN: 978-81-980623-8-3

as independent variables, while hardness and drug release were chosen as responses. Tablets were coated with a semipermeable membrane and evaluated for hardness, friability, weight variation, drug content, swelling index, and in vitro dissolution studies. The optimized formulation was further subjected to stability studies as per ICH guidelines. Pre-formulation results confirmed the purity and compatibility of acarbose with excipients. Granules showed good flow properties, and tablets exhibited acceptable hardness, friability, and content uniformity. The factorial design analysis revealed that both mannitol and microcrystalline cellulose positively influenced hardness and cumulative drug release. The optimized formulation (F3) achieved 70.55% release at 8 h and 97.36% release at 24 h, demonstrating a controlled release profile. Stability studies confirmed reproducibility and robustness of the optimized batch. The study successfully demonstrated the development of acarbose osmotic tablets using a QbD-based factorial design approach. The optimized formulation provided sustained and predictable drug release over 24 hours, which can potentially reduce dosing frequency, enhance glycemic control, and improve patient adherence. Further in vivo and clinical studies are needed to confirm bioavailability and therapeutic benefits.

**Keywords**: Acarbose, controlled porosity osmotic tablets, factorial design, sustained release, Quality by Design, optimization, diabetes mellitus.

## OPTIMIZATION AND EVALUATION OF TOPICAL GEL CONTAINING SOLID LIPID NANOPARTICLES LOADED WITH CICLOPIRON OLAMINE

Poovizhi Poongavanam*[1],Sindhuja Balaji[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4].
1234Department of pharmaceutics ,Kamalakshi Pandurangan College of Pharmacy,
Ayyampalayam, Tiruvannamalai, Tamil Nadu.

Topical drug delivery has emerged as a promising strategy for the management of superficial fungal infections and various skin diseases. Ciclopirox olamine, a broad-spectrum antifungal agent, is widely used but faces challenges such as limited permeability and inconsistent retention when delivered through conventional dosage forms. To address these drawbacks, solid lipid nanoparticles (SLNs) were formulated and incorporated into a gel base with the objective of enhancing skin penetration, sustaining drug release, and improving therapeutic performance. The nanoparticles were systematically optimized by selecting appropriate lipids, surfactants, and preparation techniques. Characterization parameters including particle size, zeta potential, entrapment efficiency, and morphology confirmed the formation of stable nanosized carriers. The SLN-based gel was further evaluated for its pH, viscosity, spreadability, drug content, and in-vitro release profile. Comparative analysis with a marketed gel demonstrated superior release kinetics and prolonged retention from the developed formulation. Antifungal testing indicated improved activity against fungal strains, highlighting the potential Clinical relevance of the system. Overall, the study suggests that an SLN-incorporated gel of Ciclopirox olamine represents an effective novel topical delivery platform with advantages of Controlled release, enhanced antifungal efficacy, and improved patient compliance.

**Keywords**: Solid lipid nanoparticles, Ciclopirox olamine, Topical gel, Antifungal activity.

**PC-786**

## DEVELOPMENT & CHARACTERIZATION OF NOVEL FILM FORMING SPRAY FOR TOPICAL PSORIASIS THERAPY

Uma D. Patel*, Puja P. Gianani, Nalini S. Kurup.
PRIN.K.M.KUNDNANI COLLEGE OF PHARMACY COLABA, MUMBAI-400005
umap703821@gmail.com

Psoriasis is a chronic autoimmune skin disorder marked by red, scaly, and inflamed lesions that greatly affect a patient's quality of life. Conventional topical treatments, including creams and ointments, often face limitations such as poor spreadability, greasy texture, and inadequate skin adherence, leading to reduced patient compliance. In this research work, an attempt was made to develop a film-forming spray as an alternative topical delivery system for psoriasis management. The formulation was designed using suitable film-forming polymers, plasticizers, and penetration enhancers to ensure ease of application, rapid drying, and the formation of a uniform, flexible film over the affected area. The prepared sprays were systematically evaluated for key parameters including pH, viscosity, spray pattern, drying time, film thickness, folding endurance, drug content, and in-vitro release profile. Skin permeation and retention studies further confirmed the ability of the formulation to deliver the drug locally with sustained action. Stability testing under ICH conditions established the robustness of the optimized spray. Optimization of the formulation was carried out using Design Expert (DoE) 13 software based on preliminary experimental findings. The pH of the optimized formulation ranged between 5–7, confirming its suitability for topical application. The drying time varied from 2–7 minutes, allowing efficient and uniform film formation. The drug content was consistently within 95–105%, indicating homogeneous distribution throughout the formulation. In vitro drug release studies demonstrated a sustained release profile, suggesting prolonged drug retention at the application site. Overall, the results suggest that the film-forming spray not only overcomes the drawbacks of conventional topical systems but also offers a patient-friendly, non-greasy, and effective therapeutic approach for long-term psoriasis management.

**Keywords**: Psoriasis, film-forming spray, topical drug delivery, patient compliance, sustained release

## IMPLANTABLE DRUG DELIVERY SYSTEM

Vaibhav Kamlakar Kakde,Mrs Ankita Mandekar,Mr Sumit Kolte
Nagpur College of Pharmacy, Nagpur, Maharashtra.
vaibhavkakde434@gmail.com

Implantable drug delivery systems (IDDS) represent a revolutionary advancement in modern medicine, providing a controlled, sustained, and localized method of drug administration. Unlike conventional routes such as oral or intravenous delivery, which often suffer from fluctuating drug levels, low bioavailability, and systemic side effects, IDDS offer precise drug release directly at the target site, enhancing therapeutic efficacy and patient compliance. These systems utilize diverse technologies, including polymeric reservoirs, osmotic pumps, biodegradable matrices, and bioerodible implants, to ensure a consistent and prolonged drug release profile. Recent innovations in nanotechnology, bioresponsive materials, and wireless-controlled implants have further expanded the capabilities of IDDS, enabling real-time dose adjustments, programmable drug release, and integration with biosensors for personalized therapy. These advancements have profound implications for managing chronic diseases, pain, cancer therapy, and neurodegenerative disorders such as Parkinson's and Alzheimer's disease. Furthermore, IDDS have demonstrated potential in delivering biologics, including peptides, proteins, and gene therapies, which are otherwise challenging to administer due to degradation in the gastrointestinal tract. Despite their numerous advantages, IDDS face challenges such as biocompatibility concerns, risk of infection, device failure, and the need for surgical implantation or retrieval. Regulatory hurdles and cost considerations also impact widespread adoption.

## DESIGN AND DEVELOPMENT OF PHARMACEUTICALLY OPTIMIZED MICONAZOLE NITRATE–ITACONIC ACID COCRYSTAL GEL: A COMPUTATIONAL AND ANALYTICAL PERSPECTIVE

Kavita Bahmani, Vikas Sain , Deepika Garg, Naman Sharma
Department of Pharmaceutical Sciences, Guru Jambheshwar University of Science & Technology, Hisar, Haryana, India

The present study focuses on the design and development of pharmaceutically enhanced topical gel formulation containing cocrystals miconazole nitrate (MIC) AND ITACONIC ACID (ITA) to improve its solubility, antifungal activity, and skin permeability. Cocrystals were synthesized using a solvent evaporation method and characterized via FTIR, PXRD, DSC, 1HNMR and SEM to confirm their formation and evaluate physicochemical properties. Quantum chemical calculations using density functional theory (DFT) at the CAM-B3LYP/6-31++G (d,p) level were employed to understand the electronic interactions and molecular geometry of the drug-coformer system. Crystal explorer 17.01 analyses was performed to visualize and quantify intermolecular

ISBN: 978-81-980623-8-3

interactions through Hirshfield analysis, revealing strong hydrogen bonding and vander waal forces contributing to cocrystal stability. Molecular electrostatic potential (MESP) mapping further identified for potential active sites and highlighted enhanced polarity and hydrogen bonding capacity in cocrystal. A topical gel was formulated using carbopol 940 as gelling agent and evaluated for pH, spreadability, viscosity, drug content and in vitro diffusion. The gel exhibited favorable physiocochemical properties and improved drug release compared to pure drug. This integrated approach highlights the potential of MIC-ITA cocrystals in potential antifungal therapy, supported by both experimental and computational insights.

Guru Ghasidas Vishwavidyalaya , Bilaspur Chhattisgarh INDIA-495009

Diabetes mellitus (DM) is a major global health concern, with a growing patient population and associated complications. Traditional treatments often fall short due to the complex nature of the disease. Recent advances in nanotechnology, particularly the use of zinc oxide nanoparticles (ZnO NPs), offer promising solutions. This review aims to highlight the eco-friendly, economical, and biocompatible characteristics of ZnO NPs, with a focus on green synthesis techniques for their production. It also explores the green synthesis of ZnO NPs using natural resources, such as microorganisms and plant extracts, which act as stabilizing and reducing agents. It examines the potential of these nanoparticles in improving medicinal properties, particularly through their antibacterial, antidiabetic, and antioxidant activities. The possibility of combining ZnO NPs with other nanomaterials is also investigated, with an emphasis on applications in biosensing, therapeutics, and diagnostics. ZnO NPs synthesized through green methods demonstrate significant potential in enhancing insulin sensitivity, glucose management, and preventing diabetes-related complications. Their improved medicinal properties, including antibacterial, antidiabetic, and antioxidant activities, are highlighted. This review also identifies opportunities for the development of combination products and discusses the transition from laboratory-scale research to industrial-scale production. Extensive safety and clinical studies are required to confirm the safety and efficacy of ZnO NPs, paving the way for regulatory approval and wider adoption in medical applications. This review underscores the importance of medicinal plants and biogenic approaches for the synthesis of zinc oxide nanoparticles and calls for further research to explore the full potential of ZnO NPs in diabetes management and beyond.

**FORMULATION AND DEVELOPMENT OF BILAYER TABLET USING OROS TECHNOLOGY FOR ANTI-DIABETIC DRUG**

Supriya Devnath1,2#, Mansee Nagdev1,2*
Rungta College of Pharmaceutical Science and Research, Kohka-Kurud Road, Bhilai, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka-Kurud Road, Bhilai, INDIA-490023
Supriyadevanth8@gmail.com

The present study focuses on the formulation and evaluation of an anti-diabetic drug using OROS (Osmotic Control Release Oral Delivery System) technology, a novel approach within osmotic drug delivery systems. This technology offers significant clinical advantages, including enhanced patient compliance and improved treatment tolerability through controlled drug release. A bilayer osmotic tablet was developed, comprising a drug-containing pull layer and an excipient-based push layer. Pre-formulation studies and physical compatibility assessments were conducted to optimize the formulation. Multiple trials were undertaken to refine granulation and compression characteristics, leading to a successful batch that demonstrated desirable performance in comparison to the reference product. The formulation process included strategic adjustments in excipient ratios and membrane coating techniques to improve drug release and mechanical stability. Evaluation parameters such as dissolution behavior across various pH media, particle size, and stability were assessed to ensure product reliability. The research culminated in the development of a robust extended-release formulation suitable for generic market entry. The challenges encountered during formulation provided valuable insights into the intricacies of osmotic drug delivery, offering a foundation for future advancements in pharmaceutical development and tailored therapeutic solutions.

**ENHANCING FLUTAMIDE SOLUBILITY AND DISSOLUTION: FORMULATION DEVELOPMENT OF NANOCRYSTAL TABLETS**

Vucha Saili and Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
Saili4v@gmail.com

The development of oral disintegrating tablets (ODTs) presents a promising strategy for enhancing the bioavailability of poorly water-soluble drugs. This study explores the formulation of nanocrystal-based ODTs to improve the solubility and dissolution rate of Flutamide, a widely used nonsteroidal antiandrogen for prostate cancer treatment. Utilizing Solvent Antisolvent precipitation technique using 23 factorial design, which three variables namely concentrations of stabilizer, ratio of solvent and antisolvent and stirring speed were kept at two levels, Flutamide nanocrystals were prepared and subsequently incorporated into ODTs through direct compression employing CCS and SSG as super disintegrate agents at different concentrations like 10 mg, 15 mg & 20mg. The physicochemical properties of the nanocrystals were characterized by particle size analysis and saturation solubility. The ODTs were evaluated for hardness, friability, disintegration time, and dissolution profile. Results indicated that the nanocrystal-based ODTs exhibited a significant increase in dissolution rate compared to API Flutamide, with a notable improvement in solubility. Out of six formulations, the tablets which contain 20 mg of CCS (F3) had shown low in vitro disintegration time 10.6 sec and highest drug release profile i.e. 95.02 % which releases the drug within 12 minutes. This novel approach demonstrates the potential of nanocrystal-based ODTs as an effective means to enhance the therapeutic efficacy of Flutamide, offering a viable solution for improving patient compliance and clinical outcomes.

**Keywords**: Nanocrystals, Oral disintegrating tablets (ODTs), Dissolution rate, Direct compression, Nonsteroidal antiandrogen and Prostate cancer treatment.

**THE ALTERNATIVE OF PLASTIC PACKAGING IN PHARMACEUTICAL INDUSTRIES TO MANAGE MICROPLASTICS AND POSSIBLE IMPACT ON HUMANS.**

Lavanya Digambar Dhamane, Krutika Channe, Vinod Thakare
Nagpur College of Pharmacy, Nagpur, Maharashtra, India – 441110.
lavanyadigambardhamne@gmail.com

Around 360 million tons of plastic are produced and half of this is destined for single use items. On degradation plastic. produces nano and microplastics. Research on human cells revealed that nano and micro plastics trigger various cellular responses including cytotoxicity, genotoxicity etc. The contact of drug with plastic polymers leads to sorption of drugs on plastic polymer and it also depends on storage and transportation conditions. To reduce these chances, we need innovation in food and pharma packaging industries. We should consider alternatives such as bioplastics. One such bioplastic or eco packaging can be prepared with onion peel with polymer blend.

**Keywords**: Drug-polymer interaction, Packaging innovation, onion peel polymer, cytotoxicity.

**"FORMULATION, DEVELOPMENT AND EVALUATION OF OPHTHALMIC NANOEMULGEL CONTAINING LIFITEGRAST"**

Shehzad Siraj Bhojani, Patel Shruti Ranjitbhai, Mrs. Bhoomi S. Patel
Smt. B.N.B Swaminarayan Pharmacy College, Salvav – Vapi, India - 396191

Here we report on the design, development, and in vitro and in vivo evaluation of an ocular nanoemulgel of Lifitegrast, a nonsteroidal anti-inflammatory agent for the treatment of dry eye disorder. Lifitegrast, due to its low ocular bioavailability and short precorneal elimination, needs a developed delivery system to increase its therapeutic effectiveness. Our objective was to overcome these limitations and formulate a nanoemulsion-based gel system that could enhance the ocular residence time of the drug, its permeation through various ocular barriers and sustained drug delivery. High-energy emulsification method was used with suitable oil, surfactant and co-surfactant in order to achieve the drug solubilization and stability. The optimized nanoemulsion was further entrapped in a gel matrix with a mucoadhesive polymer to obtain nanoemulgel for ocular delivery. The optimized formulation was characterized for droplet size, zeta potential, pH, viscosity, drug content, in vitro drug release, ex vivo permeation, and ocular irritation studies. The nanoemulgel formulation was found to have promising physicochemical characteristics with sustained drug delivery and enhanced penetrability as compared to conventional formulations. The Preparation Was Nonirritant and Suitable for Ocular Application. In conclusion, the formulated nanoemulgel of Lifitegrast is a potential approach for improving ocular bioavailability and therapeutic effect in the treatment of dry eye disorder.

**Keywords**: Nanoemulgel, Ocular bioavailability, Mucoadhesive polymer, Sustained drug delivery, Lifitegrast.

**FORMULATION AND CHARACTERIZATION OF ORAL DISPERSIBLE TABLETS OF FEXOFENADINE HYDROCHLORIDE USING THE SUBLIMATION TECHNIQUE**

PV Kamala Kumari, P Preethi
Department of Pharmaceutics, Vignan Institute of Pharmaceutical Technology, Duvvada, Beside VSEZ, Visakhapatnam-530049, Andhra Pradesh, India.
kamalaparavastu@gmail.com

The primary objective of this study was to formulate and characterize an oral dispersible drug delivery system incorporating Fexofenadine Hydrochloride (FEX) as the model drug. Oral dispersible tablets of FEX were prepared by the direct compression method, employing crospovidone as a superdisintegrant and camphor as a sublimating agent. Microcrystalline cellulose (MCC) was used as a diluent, while magnesium stearate served as a lubricant. The dissolution behavior of the formulations was evaluated in phosphate buffer solution (pH 6.8). In addition, the prepared tablets were assessed against established criteria for oral dispersible tablets and compared with commercially available formulations. Stability studies were conducted at 30°C/65% RH and 40°C/75% RH, demonstrating that the optimized formulation retained stability under these conditions. The drug release profile of the developed tablets was found to be consistent and complete within 60 minutes, showing comparable performance to the commercial product.

**Keywords**: Fexofenadine Hydrochloride; oral dispersible tablets; sublimation technique; direct compression method.

**FORMULATION AND EVALUATION OF BUCCALFILMS CONTAINING CINNARIZINE CO-CRYSTALS FOR SOLUBULITY ENHANCEMENT**

Satyalakshmi Siragam*, Sampath Kommisetty, Rama Rao Bora
Department of Pharmaceutics, Vignan Institute of Pharmaceutical Technology, Duvvada, Beside VSEZ, Visakhapatnam-530049, Andhra Pradesh, India.
lakshmisiragam48@gmail.com

Cinnarizine is a commonly prescribed antihistamine for motion sickness, a limitation caused by its poor water solubility results dissolution-limited absorption. Cinnarizine–sodium saccharin cocrystals were formulated and incorporated into buccal films to improve solubility and enable controlled release. Successful cocrystals were obtained through solvent evaporation and validated by FTIR, DSC, XRD, and SEM examinations, which showed distinct crystalline structures. Studies on solubility found that the cinnarizine solubility in the cocrystal form was 3.2 times higher than in the pure drug ($p < 0.05$). The optimized buccal films exhibited uniform thickness of 0.21 ± 0.02 mm, a tensile strength of 5.6 ± 0.4 MPa, and the ability to withstand more than 300 folds, thus indicating suitable mechanical robustness. In-vitro dissolution showed sustained drug release of up to 92.4 ± 2.1% within 6 h, which was significantly higher than pure cinnarizine films ($p < 0.05$). The films displayed impressive mucoadhesive properties, maintaining a residence time of 18.3 ± 1.2 g in the mouth. The results show that cinnarizine–sodium saccharin cocrystal-based buccal films represent a promising and patient-friendly approach for improving the solubility, bioavailability, and therapeutic effectiveness of cinnarizine.

**DEVELOPMENT OF CYCLODEXTRIN-FUNCTIONALIZED CMC-PVA HYDROGELS FOR CONTROLLED DELIVERY OF CURCUMIN IN WOUND HEALING APPLICATIONS**

Vishwajeet Ghorpade and Ankita Devalekar
Department of Pharmaceutics, Krishna Institute of Pharmacy, Krishna Vishwa Vidyapeeth (Deemed to be University), Karad, Maharashtra, India- 415539
ghorpadevs.kip@gmail.com

This study introduces cyclodextrin-grafted carboxymethylcellulose and polyvinyl alcohol hydrogel films crosslinked with citric acid for wound healing, focusing on curcumin (CUR) delivery. Films were fabricated via solvent casting, pre-dried at 50°C for 24 h and cured at 140°C for 10 min, with optimal CA concentration at 20%. The films were characterized by ATR-FTIR, TGA, DTG, and solid-state 13C NMR analyses and evaluated for active β-cyclodextrin (βCD) content, carboxyl content, tensile strength, swellability, protein adsorption, permeability, drug loading and release, cytocompatibility, and in vivo wound healing activity. This study addressed challenges of βCD-CMC hydrogel films, including rapid matrix erosion and low loading of poorly soluble drugs. Increasing PVA concentration led to higher active βCD and carboxyl content in the hydrogel films. Instrumental analysis confirmed grafted βCD and ester crosslinks in the hydrogel films. The βCD-CMC-PVA hydrogel films showed superior mechanical strength compared to βCD-CMC films, with BCP3 batch achieving 12.78 ± 0.29 kg/mm² tensile strength. PVA incorporation enhanced swellability and CUR loading, with BCP2 showing highest drug uptake. Drug release studies showed initial burst release of 10–35% CUR within 30 min, followed by sustained release beyond 24 h. The hydrogels demonstrated low protein adsorption and prevented microbial penetration for seven days, indicating their potential as wound-dressing materials. In vivo studies in rats confirmed notable wound-healing activity. These findings suggest cyclodextrin-grafted CMC-PVA hydrogel films are promising for treating wounds with discharge, offering controlled delivery of antibacterial agents.

**NANOCARRIER-BASED DRUG DELIVERY SYSTEMS: REVOLUTIONIZING THERAPEUTIC PRECISION**

Nanshi Chandra1,2#, Girish Kumar Sahu1,2, Chiranjeev Sahu1,2, Parag Jain1,2* and Ajazuddin1,2
Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh, INDIA-490023
Department of Pharmacy, Rungta International Skill University, Kohka, Kurud Road, Bhilai, INDIA-490023

The development of drug delivery systems based on nanoparticles has revolutionized pharmaceutical research by enabling controlled release and site-specific response. Nanocarriers enhance (-availability, -therapeutic index, -solubility, and-or) clearance(b) and nonspecific binding in vivo relative to conventional formulations. Liposomes, dendrimers, polymersomes and inorganic NPs are often studied and employed as they can be easily tuned to possess seven adjustable physicochemical properties. Multivalent surface functionalization and ligand-targeting is achievable with dendrimers while liposomes encapsulate hydrophobic/hydrophilic drugs. Micellar polymers mainly solubilize hydrophobic drugs, whilst the (optical or magnetic) properties of inorganic NPs have been exploited in diagnosis and theranosis. There

ISBN: 978-81-980623-8-3

have been advances in drug delivery methods, including ligand–receptor-mediated delivery, targeted to the receptors on overexpressed cancer cells; stimulus-responsive release systems such as pH-sensitive release at tumor sites; and endosomal escape of drugs to enable cytoplasmic drug delivery. Centrally focused on cancer treatment, nanocarriers take advantage of the enhanced permeability and retention (EPR) effect to passively accumulate within tumors and reduce side effects, thus increasing patient survival. Integration with imaging probes enable dynamic monitoring of biodistribution and response in real time when using nanocarrier technologies. Nevertheless, immunogenicity, scale-up reproducibility, stability and regulatory approval remain bottlenecks for clinical translation. AI receptor-targeted drug delivery, nanodrug for precision medicine, and stimuli-responsive intelligent drug carrier shapethe landscape of targeted therapy in the next century. The nanocarrier–delivery intersection of material science, molecular pharmacology, and translational science could transform precision medicine in her opinion.

2. Department of Pharmacy, Rungta International Skills University, Kohka, Kurud Road, Bhilai, INDIA-490023

Wound healing is a complex biological process involving hemostasis, inflammation, proliferation, and remodelling phases, where efficient reepithelialization is crucial for successful tissue regeneration. Recent advances in nanotechnology have opened new avenues for designing multifunctional nanocarriers capable of enhancing tissue repair. In this study, a novel plumgin-loaded nanogel was developed and evaluated for its potential to accelerate reepithelialization and promote tissue regeneration. The nanogel was synthesized using a biocompatible polymeric network optimized for sustained drug release, enhanced bioadhesion, and penetration into the wound microenvironment. Characterization studies revealed uniform particle size distribution, high encapsulation efficiency, and stable physicochemical properties suitable for topical application. In vitro assays demonstrated that the nanogel significantly enhanced keratinocyte proliferation and migration, key indicators of reepithelialization. Additionally, anti-inflammatory and antioxidant activities of the nanogel were observed, which further supported the regenerative process by modulating the wound microenvironment. In vivo studies using a full-thickness excisional wound model confirmed accelerated wound closure, improved collagen deposition, and enhanced epithelial layer formation compared to control treatments. Histopathological analysis corroborated the improved tissue architecture and reduced inflammatory infiltration, highlighting the synergistic effect of plumgin within the nanogel matrix. These findings suggest that the plumgin nanogel represents a promising therapeutic strategy for enhancing wound healing through targeted reepithelialization and tissue regeneration, offering potential for future clinical translation in chronic and acute wound management.

**Keyboards**: Plumgin, Nanogel, Wound healing, Reepithelialization, Tissue regeneration, Anti-inflammatory activity

**TRIMYRISTIN-LOADED POLYMERIC ORAL THIN FILM FOR THE TREATMENT OF MOUTH INFECTION.**

Kanti Chandra 1,2# , Alka Patel1,2,*
1. Rungta College of Pharmaceutical Science and Research, Kohka, Kurud Road, Bhilai, INDIA-490023
2. Department of Pharmacy, Rungta International Skills University, Kohka, Kurud Road, Bhilai, INDIA-490023

Oral infections remain a significant global health challenge, often associated with pain, impaired oral functions, and risk of systemic complications. Conventional therapies such as mouthwashes and systemic drugs are limited by poor patient compliance, inadequate site-specific delivery, and short drug retention in the oral cavity. In this study, we developed and evaluated Trimyristin-loaded polymeric oral thin films (OTFs) as a novel drug delivery system for the localized management of mouth infections. The films were prepared using a solvent casting technique with biocompatible polymers to ensure mucoadhesion, rapid disintegration, and controlled drug release. Physicochemical characterization, including thickness uniformity, folding endurance, tensile strength, and surface morphology, confirmed the films' mechanical stability and ease of handling. Drug loading efficiency and in vitro release studies demonstrated sustained release of Trimyristin, while antimicrobial assays revealed significant inhibitory activity against common oral pathogens. Furthermore, swelling index and mucoadhesion studies indicated prolonged residence time at the infection site, potentially enhancing therapeutic efficacy. The developed OTFs offer a patient-friendly, non-invasive alternative for effective treatment of oral infections, combining targeted delivery, improved stability, and enhanced patient compliance.

**Keywords**: Trimyristin, Oral thin film (OTF), Mucoadhesion, Mouth infection therapy

**PC-800**

**A NOVEL RETINYL PALMITATE PATCH FOR SKIN REPAIR**

Rasha Fahmi P, Jisha Mohanan and Shahana.
College of Pharmaceutical Sciences, Govt. Medical College, Trivandrum, Kerala, India – 695011

Transdermal drug delivery systems (TDDS) offer a non-invasive route for sustained and controlled administration of drugs, improving patient compliance and bypassing hepatic first-pass metabolism. Retinyl palmitate (RP), an ester of vitamin A, is widely valued for its anti-aging, anti-acne, antioxidant, and skin-renewing properties but faces challenges of poor skin penetration and instability in conventional topical formulations. This study aimed to develop and evaluate transferosome-loaded transdermal patches of RP to address these limitations. Transferosomes were prepared by the thin-film hydration method using phosphatidylcholine and Tween 80, then characterized for vesicle size distribution and zeta potential to confirm uniformity and stability. RP-loaded patches were fabricated using the solvent casting technique with hydroxypropyl methylcellulose (HPMC) as the polymer matrix, oleic acid as the permeation enhancer, and glycerol as the plasticizer. A central composite design (Design-Expert 13) was applied to optimize polymer and enhancer concentrations with respect to folding endurance and percentage drug release. The optimized patches showed smooth texture, uniform thickness, good flexibility, near-neutral surface pH, acceptable moisture content, and adequate mechanical strength. In vitro drug release studies using Franz diffusion cells showed cumulative release of 93.36% over seven hours, indicating efficient permeation through the membrane and sustained delivery. Incorporating RP into transferosome-based patches enhanced its stability and skin penetration compared to conventional formulations. This approach offers a patient-friendly, advanced platform for skincare applications targeting aging, acne, and hyperpigmentation, while reducing adverse effects commonly linked with topical retinoid therapy. The findings support further development of transferosome-based transdermal systems for cosmetic and therapeutic uses.

**Keywords**: Transdermal patch, Transferosome, Retinyl Palmitate, Skin care, In-vitro drug release.

**FORMULATION AND EVALUATION OF PULS IN CAP DRUG DELIVERY SYSTEM OF VALSARTAN**

Adduri Saranya Veera Gangotri, P.Phaneendra
Department of Pharmaceutical Sciences, Vikas institute of Pharmaceutical Sciences, Near Air Port, Rajahmundry,East Godavari District, Andhra Pradesh, India-533102.
saranyaveeragangotri@gmail.com

This study presents the development of a Pulsincap drug delivery system for valsartan, aimed at the chronotherapeutic management of hypertension by targeting the early morning blood pressure surge. The system consists of a water-insoluble capsule sealed by a swellable hydrogel plug, designed to provide a predetermined "lag time." In-vitro evaluation confirmed the formulation's quality, with tests on the powder, hydrogel plug, and final capsule. Dissolution studies were crucial, successfully demonstrating the intended lag time followed by a

ISBN: 978-81-980623-8-3

rapid, pulsatile drug release. In-vivo pharmacokinetic studies in a crossover design showed a delayed Tmax for the Pulsincap compared to a standard tablet, validating the lag time. Finally, chronotherapeutic efficacy was confirmed through 24-hour ambulatory blood pressure monitoring, which demonstrated the Pulsincap's superior ability to control high morning blood pressure, thereby enhancing patient outcomes.

**Keywords**: puls in cap drug delivery system, valsartan, chronotherapeutic, Swellable hydrogen plug, lag time, ambulatory blood pressure monitoring

## FORMULATION DEVELOPMENT AND EVALUATION OF 3D PRINTED BI-LAYER FLOATING TABLETS OF ANTI-PSYCHOTIC DRUG UTILIZING FUSED DEPOSITION MODELLING TECHNIQUES

Abhiram Patil, Mayank Sharma
Department of Pharmaceutics, School of Pharmacy & Technology Management, SVKM'S NMIMS Deemed-to-be University, Shirpur, Maharashtra 425405.
abhiramp2104@gmail.com

Three-dimensional (3D) printing, also referred to as additive manufacturing, is considered a game-changing technology in pharmaceuticals. 3D printing (3DP) offers the possibility of manufacturing individually dosed solid oral dosage forms flexibly and on demand with a high level of precision and accuracy in the doses. Lurasidone Hydrochloride, classified under BCS class II with low solubility, was chosen. The objective behind developing a modified release 3D printed tablet was to improve solubility, bioavailability, and decrease dosing frequencies. This study aimed to develop 3D printed drug-loaded bilayer floating tablets for immediate release and sustained release action. The tablet was printed 3 Dimensionally by using the fused deposition modelling printing process with the aid of Kollidon VA64, Kollidon 30, Kollidon SR, Eudragit S100 as polymer, and Triacetin as plasticizer. The infrared analysis showed no interaction between the drug and other polymers. With the diameter of the extruder set to 1.5 mm, the filament required for printing the tablet was prepared by processing the blend mixture at 160 °C at a speed of 50 rotations per minute using a twin screw lab scale extruder, Haake Minilab. The optimization of filament for both release patterns was carried out, and the most optimized batch was selected for printing through the fused deposition modelling process. The immediate release tablet showed 97.5 % drug release, while the sustained release tablet showed 67.5 % drug release. Floating of a 3D printed tablet was observed when 90 % of the immediate layer had fully dissolved.

## FORMULATION AND EVALUATION OF CHITOSAN BASED POLYMERIC NANOPARTICLES OF AN ANTI - ALZHEIMER'S DRUG MEMANTINE HYDROCHLORIDE

Tanniru Sirisha, Sadhu Venkateswara Rao
Department of Pharmaceutics,
Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
sirishasirishat6@gmail.com

The aim of the study was to develop Memantine HCl loaded chitosan - sodium tripolyphosphate (STPP) nanoparticles using Ionic gelation method and evaluates their physicochemical properties and in-vitro release studies for possible targeted delivery to the brain. The objective was to fabricate polymeric nanoparticles for better controlled and targeting action of drug, which also overcome the problems associated with conventional formulations like multidose therapy, poor patient compliance and high cost. Memantine HCl loaded chitosan nanoparticles (F1 to F6) were prepared by Ionotropic gelation method. The formulated nanoparticles were evaluated for external morphological characters, determination of particle size analysis, zeta potential, drug content, entrapment efficiency and in-vitro release studies. The particle size varied from 148 to 317 nm and zeta potential was in negative and its value found to be - 46.4 mV. The drug content for the Memantine HCl loaded chitosan nanoparticles varied from 69.5 ± 7.2% to 87.9 ± 1.2%. The entrapment efficiencies were found to be minimum and maximum of 55.50 ± 2.4% and 86.30 ± 3.6%. The percentage yields of all formulations were in the range of 48.24 ± 1.24 to 86.13 ± 1.37%. In-vitro release of drug follows zero order and showed sustained release behaviour for a period of 24 hr. The optimized formulation contains 3:1 ratio of chitosan & STTP and demonstrated successful sustained release. Memantine HCl loaded chitosan nanoparticle is a potential new delivery system for treatment of Alzheimer's disease.

**Keywords**: Alzheimer's disease, Polymeric nanoparticles and Ionotropic gelation.

## FORMULATION AND EVALUATION OF HERBAL SKIN CREAM FOR WOUND HEALING

Sindhuja Balaji[1], Poovizhi Poongavanam[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4]
Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai

Wound healing is a normal physiological process, but delayed recovery often leads to complications. In this context, herbal formulations have gained attention because of their safety profile and therapeutic effectiveness. The present investigation focused on the development and evaluation of a herbal skin cream formulated with selected medicinal plant extracts recognized for their antimicrobial, anti-inflammatory, and healing properties. The cream was prepared using a suitable base and assessed for various physical parameters including color, consistency, spreadability, pH, homogeneity, and stability. Herbal actives were incorporated at appropriate concentrations, and the resulting formulation exhibited desirable texture and easy removability. The evaluation confirmed acceptable pH values within the normal skin range, absence of phase separation, and stability under storage conditions. Preliminary wound healing studies indicated that the herbal cream accelerated epithelialization and reduced inflammation compared to control samples. The product was non-irritant, smooth in application, and provided a soothing effect on the skin. Utilizing natural ingredients ensures better biocompatibility and minimizes side effects often associated with synthetic formulations. Overall, the study suggests that the developed herbal skin cream could be a safe, effective, and cost-friendly option for wound care. However, further pharmacological and clinical investigations are necessary to validate its therapeutic activity and elucidate its mechanism of action.

**Keywords**: Herbal cream, Wound healing, Formulation, Evaluation, Antimicrobial, Stability

## NOVEL CONTROLLED RELEASE VALPROIC ACID LOADED NANOPARTICLES: AS HDAC INHIBITOR DRUG DELIVERY TO COLON CANCER ASSOCIATED WITH DIABETES MELLITUS

Shivraj Popat Jadhav1, Deepak Devidas Sonawane1, Sunil Kashinath Mahajan1
1Shreeshakti Shaikshanik Sanstha's Divine College of Pharmacy, Satana, Nashik, Maharashtra, India, 423301.
Shivraj Popat Jadhav, Shreeshakti Shaikshanik Sanstha's Divine College of Pharmacy, Satana, Nashik, Maharashtra, India, 423301.

Diabetes mellitus is strongly linked to colorectal cancer, with hyperinsulinemia and epigenetic dysregulation as key contributors. Histone deacetylase (HDAC) enzymes represent common therapeutic targets in both conditions. Valproic acid, a well-known HDAC inhibitor, improves insulin sensitivity, preserves β-cell function, and exhibits anticancer activity. However, conventional delivery suffers from poor colon specificity, systemic toxicity, and limited efficacy. This study focused on developing colon-targeted, controlled-release valproic acid nanoparticles using pH-sensitive polymers (Eudragit L100, Eudragit RS100, and chitosan) via solvent evaporation, nanoprecipitation, and probe sonication. Eighteen formulations (F1–F18) were prepared and systematically evaluated. The optimized formulations, F6 (Eudragit L100) and F12 (Eudragit RS100), demonstrated particle sizes of 265–290 nm, polydispersity index <0.3, zeta potential around −22 mV, and high entrapment efficiency (96.46% and 96.54%). Chitosan-based formulations (F15, F16) also showed good entrapment (79.5% and 72.7%). In vitro studies confirmed sustained drug release of 67.6% (F6) and 75.2% (F12) over 12 hours at pH 6.8, validating colon-targeted delivery. FTIR and DSC analyses revealed no drug–polymer interactions,

ISBN: 978-81-980623-8-3

while SEM confirmed spherical nanoparticle morphology. Stability testing at 40 °C/75% RH for three months indicated no significant change in particle size or entrapment. The developed nanoparticles showed improved bioavailability and prolonged activity compared to plain valproic acid. This novel colon-targeted system reduces dose frequency, minimizes systemic side effects, and enhances patient compliance, offering dual therapeutic potential for type 2 diabetes mellitus and colorectal cancer.

**Keywords**: Valproic acid, HDAC inhibitor, Colon-targeted nanoparticles, Eudragit, Controlled release, Colorectal cancer.

**PC-806**

**EFFECT OF VARIABLES ON FORMULATION OF DICLOFENAC POTASSIUM-LOADED ALBUMIN MICROSPHERES**

Husna Fahmi Kanhirappalli, Lidiya V S
College of Pharmaceutical Sciences, Govt. Medical College,
Kannur, Kerala, India-670503
husnafahmikp@gmail.com

This study investigated the influence of formulation variables such as surfactant concentration, speed of rotation, and processing temperature on the preparation of diclofenac potassium-loaded albumin microspheres. Microspheres were prepared by a simple emulsification method followed by heat denaturation, using egg albumin as the polymer and glutaraldehyde as the crosslinking agent. Three formulations (F1, F2, and F3) were developed under varied conditions, with the drug–polymer mixture dispersed in liquid paraffin containing Tween 80 and stabilized before recovery by decantation and drying. The microspheres were characterized for percentage yield, entrapment efficiency, and in vitro release. Among the formulations, F2 prepared at 0.01% surfactant concentration, 800 ± 10 rpm, and 90 ± 10 °C showed satisfactory performance, achieving an entrapment efficiency of 56.37%, indicating partial but stable encapsulation within the albumin matrix. In vitro release was assessed in phosphate buffer saline (pH 7.4) using both the diffusion membrane technique and USP dissolution apparatus II. The diffusion membrane method demonstrated gradual and sustained release over 300 minutes, while dissolution studies with microspheres encapsulated in hard gelatin capsules revealed a cumulative release of 107.25% in the same period, reflecting nearly complete release with minor experimental variation. Comparative evaluation of F1, F2, and F3 highlighted the significance of formulation variables in modulating release profile. Overall, the findings confirm that diclofenac potassium-loaded albumin microspheres can be successfully prepared with satisfactory yield and encapsulation, presenting a promising approach for sustained drug delivery. The formulation variables must be optimized to develop successful microspheres.

**MULTICOMPONENT COCRYSTALS OF ATORVASTATIN CALCIUM: FORMULATION, CHARACTERIZATION, SEDEM ANALYSIS AND PHARMACOKINETIC EVALUATION**

Deepak Kulkarni, Sanjay Pekamwar
School of Pharmacy SRTM University, Nanded, Maharashtra, India, 431606.
deepakkulkarni68@gmail.com

Atorvastatin calcium (ASC) is promising lipid lowering agent and well explored in global pharmaceutical market. Atorvastatin calcium is struggles with poor solubility and associated bioavailability limitations. Due to poor solubility, there is unnecessary dose increment is required to achieve required therapeutic concentration which may result in increased hepatic and nephrotic load. To overcome these limitations, an attempt was made to fabricate multicomponent cocrystals of ASC with ten different cocrystal formers using microwave assisted solvent evaporation technique. After solubility analysis it was observed that, the Atorvastatin Calcium-Oxalic acid (ASC-OA) cocrystals has highest solubility. These cocrystals were subjected to various analysis like FTIR, DSC and XRD to confirm the formation of cocrystals. These cocrystals showed improved flow properties and stability as compare to pure drug. The SeDeM analysis was implemented to see the comparative flow and compressibility behavior of pure ASC and ASC-OA cocrystals. The cocrystals were formulated into tablet using experimental design and optimization and further subjected to comparative dissolution study. ASC-OA cocrystal tablet showed improved dissolution in comparison with pure ASC tablet. In vivo pharmacokinetic study demonstrated the improved systemic availability of ASC when administered in the form of cocrystal. All the pharmacokinetic parameters like Cmax, AUC0-t, AUC0-∞ and MRT were found to be improved when administered as a cocrystals. The stability and shelf analysis demonstrated the comparatively better stability cocrystal tablets. Overall, this crystallographic modification resulted in improved solubility, dissolution and bioavailability.

**Keywords**: Atorvastatin calcium, cocrystals, solubility, dissolution, bioavailability

**PC-808**

**FUSIDIC ACID NANOSPONGE GEL: A NOVEL APPROACH TO ENCHANCING SKIN BACTERIAL INFECTION TREATMENT**

Sunkara Jyothi Sree, Sadhu Venkateswara Rao
Department of Pharmaceutics,
Vijaya Institute of Pharmaceutical Sciences for Women
Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
srij3460@gmail.com

The present study focuses on the development and evaluation of a Fusidic Acid-loaded nanosponge-based gel as an innovative topical formulation for improving the treatment of bacterial skin infections. Nanosponges were prepared using the emulsion solvent diffusion method, with a $2^3$ factorial design incorporating Ethyl Cellulose (EC), Eudragit, and β-Cyclodextrin (βCD). Among the formulations, F4 (high βCD and Eudragit) exhibited the best production yield and solubility enhancement, making it ideal for further gel formulation. Nanosponge-based gels were formulated using Carbopol 934P, HPMC K100, and CMC and evaluated for homogeneity, pH, viscosity, drug content, and in vitro drug release. All formulations were smooth, white, and uniform, with pH values suitable for topical application. HPMC-based gel (F2) demonstrated the most sustained drug release (81.46%), ensuring longer drug retention at the infection site, while CMC-based gel (F3) exhibited the highest drug release (97.28%). The study confirms that nanosponge-based gels enhance solubility, provide controlled and sustained drug release, and improve patient compliance by reducing dosing frequency. These findings suggest that nanosponge-based gels offer a promising approach for topical Fusidic Acid delivery, improving therapeutic efficacy in bacterial skin infections.

**Keywords**: Fusidic Acid, Nanosponge, Emulsion Solvent Diffusion, Topical Gel and Sustained Drug Release.

**SOLID DOSAGE FORMULATION OF ANTHOCYANIN AND SHORT TERM STABILITY**

Vidhya V Devan, S. Mahendran
Department of Pharmaceutics, Nehru College of Pharmacy, Pampady, Thrissur, Kerala-680588.
sreethusukesh3@gmail.com

Anthocyanin is the principal flavonoid present in Garcinia indica fruit rind, mainly as cyanidin-3-glucoside (C3G) and cyanidin-3-sambubioside (C3S). These water-soluble pigments are highly sensitive to physicochemical factors such as pH, temperature, light, and interactions with matrix components, which affect their stability and limit applications. The present study aimed to enhance anthocyanin stability through microencapsulation using different gum combinations, including gum arabic, guar gum, pectin, and inulin. Microcapsules were prepared by spray drying and freeze drying in four gum combinations. Results revealed that spray drying retained comparatively lower anthocyanin content, while freeze-dried formulations showed significantly better retention. Among the tested formulations, the gum arabic–guar gum combination exhibited the highest encapsulation efficiency. Characterization of microcapsules by drug content, micromeritic properties, SEM, and FTIR confirmed desirable physicochemical attributes. Stability studies under accelerated and ambient conditions demonstrated that microencapsulation improved anthocyanin stability compared to the pure extract. The optimized formulation was successfully developed into size-0 capsules and tablets via direct compression, with both dosage forms showing satisfactory evaluation results. Overall, microencapsulation with gum-based carriers,

ISBN: 978-81-980623-8-3

particularly gum arabic–guar gum, proved effective in improving anthocyanin stability and demonstrated potential for nutraceutical and pharmaceutical applications.

**Keywords**:Anthocyanins, Microencapsulation, Freeze drying, Gum Arabic, Stability studies

**DEVELOPMENT AND INVITRO VALIDATION OF SUSTAINED RELEASE MATRIX TABLETS OF LORNOXICAM USING NATURAL POLYMERS**

Susheel Pawar, Maka Vishwanath, Vineet Ambure, Soumya
Department Of Pharmaceutics, Sri Siddhalingeshwar College Of Pharmacy Bidar-585404 Karnataka India

Lornoxicam is a NSAIDS having rare side effects. It is used in the treatment of osteoarthritis, ankylosing spondylitis, rheumatoid arthritis etc. It has a short biological half- life of 4 hrs and eliminated rapidly. Therefore, sustained release formulation is required, which have distinct advantages when compared to conventional dosage. Present work, studies were carried on the development and in vitro validation of sustained release matrix tablets of lornoxicam using natural polymers (Pectin & Xanthan gum) with a view to obtain controlled release characteristic to achieve prolonged therapeutic effect by continuously releasing medication over a extended period of time after administration of single dose. Lornoxicam matrix tablets were formulated employing xanthan gum and Pectin in different concentrations and the tablets were evaluated for various tablet characters including drug release kinetics and mechanism. Lornoxicam matrix tablets formulated employing xanthan gum (30% w/w) provided slow and controlled release of lornoxicam over a period of 24 h. Drug release from the matrix tablets formulation containing pectin and xanthan gum follows zero order drug release with non fickian diffusion mechanism. All the tablet formulation showed compliance with pharmacopoeial standard. As the time increases, the swelling index was increased; later on, it decreases gradually due to dissolution of outermost–gelled layer of tablet into dissolution medium. Comparison between xanthan gum and pectin, it has been observed that swelling index of pectin was significantly more compared to xanthan gum. The dissolution result shows that an increased amount of polymer resulted in reduced drug release. A concentration dependent drug release is evident in case of the polymer i.e., lower concentration of polymers, release is marginally retarded at higher concentration is considerable. Prepared matrix formulation containing xanthan gum 30% is probably showing better release of 99 % drug release within 24 hours.

**Keywords**: sustained release, xanthan gum, pectin, lornoxicam.

**NANOEMULGEL AS AN ADVANCED TOPICAL CARRIER FOR CLOTRIMAZOLE; ENHANCING SOLUBILITY PERMEATION AND ANTIFUNGAL EFFICACY**

Barath Nithish Kumar[1], Senthilkumar Krishnan2, Kannabirran Vaikundam3
[123]Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai, Tamilnadu

Superficial fungal infections represent one of the most prevalent dermatological conditions, often associated with itching, discomfort, and recurrence. Despite the broad antifungal spectrum of clotrimazole, its poor aqueous solubility, limited skin penetration, and short residence time restrict its therapeutic performance in conventional topical formulations. To address these challenges, the present study focuses on the formulation and evaluation of a clotrimazole-loaded nanoemulgel as an innovative drug delivery approach. Nanoemulsions were prepared using pharmaceutically acceptable oils, surfactants, and co-surfactants, and further incorporated into a carbopol gel base to enhance spreadability, patient compliance, and retention at the site of infection. The optimized nanoemulgel exhibited a nanometric droplet size (~350 nm), narrow polydispersity index, favorable zeta potential, high drug content (> 90%), and desirable rheological properties, confirming its suitability for topical use. In vitro diffusion studies performed using Franz diffusion cells demonstrated a significant improvement in permeation and release kinetics compared to a marketed clotrimazole cream, with a permeation enhancement ratio greater than two. Antifungal assays against Candida albicans and Aspergillus niger revealed enhanced zone of inhibition, validating improved therapeutic efficacy. Skin irritation studies indicated the formulation was non-irritant and well tolerated. Collectively, these findings highlight the nanoemulgel system as a patient-friendly, efficacious, and stable platform for topical clotrimazole delivery, offering promise for superior management of fungal skin infections.

**Keywords**: Clotrimazol, Nanoemulgel, Antifungal therapy, Topical drug delivery, Permeation enhancement Novel drug delivery systems.

**OPTIMISATION OF RASAGILINE MESYLATE ENCAPSULATED PLGA NANOPARTICLES USING TAGUCHI SCREENING METHOD AND DESIGN OF EXPERIMENTS (DOE)**

Yashvita Chhabada, Khushwant S. Yadav
Shobhaben Pratapbhai Patel School of Pharmacy & Technology Management, SVKM's NMIMS (Deemed to be University), Mumbai, India
yashvitavc@gmail.com

Parkinson's diseaso (PD) manogement is challenged by progressive neurodegeneration and limited drug delivery to the brain. Rasagiline is a selective MAO-B inhibitor with potential disease-modifying effects, whose therapeutic efficiency gets restricted due to short half-life and extensive first-pass metabolism. Looking into these drawbacks this study was focused on optimizing PLGA-encapsulated Rasagiline mesylate nanoparticles (RSM-NPs) to have a prolonged drug release. A powerful dual-stage statistical optimization strategy, combining Taguchi screening with a Box-Behnken-based Design of Experiments (DoE) approach, was used to establish the design space. Nanoparticles were prepared using solvent evaporation double emulsion method using seven formulation and process parameters (polymer & stabilizer concentration, organic:aqueous ratio, temperature, volume of external phase and sonication time of primary and secondary emulsion). The optimized formulation achieved a mean particle size of 190 nm, a narrow polydispersity index of 0.22 and entrapment efficiency of 62.9%. The RSM-loaded PLGA nanoparticles (RSM-NPs) demonstrated a sustained release profile at pH 5.5 conditions over a 24-hour period. The drug release kinetics adhered to a zero-order release model, with an n-value of 0.45, indicative of Fickian diffusion. In conclusion, the successful formulation of RSM-loaded PLGA nanoparticles highlights the effective application of DoE to optimize the encapsulation of a hydrophilic drug, achieving a higher entrapment efficiency (EE) and sustained release for up to 24 hours.

**Keywords**: Rasagiline mesylate, Parkinson's disease, Taguchi design, DoE, neurotherapeutics

**PHARMACOTHERAPEUTIC POTENTIAL OF NATURAL BIOACTIVE NANOPARTICLES FOR MANAGEMENT OF NEURODEGENERATIVE DISEASE**

Roshan Sonwani
Shri Rawatpura Sarkar University, Raipur, (C.G.)
roshansonwani8@gmail.com

Neurodegenerative diseases (NDDs), including Alzheimer's (AD), Parkinson's (PD), and Huntington's (HD), are characterized by progressive neuronal loss, leading to cognitive and motor dysfunction. The limitations of current therapies such as symptomatic relief and adverse effects have spurred interest in natural bioactive compounds for their multi-target neuroprotective potential. NDDs involve protein misfolding (amyloid-β, α-synuclein) oxidative stress, mitochondrial dysfunction, and chronic neuroinflammation, contributing to neuronal death. These pathological hallmarks present targets for therapeutic intervention. Compounds like Curcumin and Resveratrol, modulate key pathways, including NF-κB (anti-inflammatory), Nrf2/ARE (antioxidant), and autophagy (clearance of toxic aggregates). Their pleiotropic effects address multiple disease mechanisms simultaneously. To overcome poor bioavailability and blood-brain barrier (BBB) penetration, advanced systems such as nanoparticles nano liposomes are being explored. These enhance stability, targeted delivery, and sustained release of bioactive compounds. Preclinical studies demonstrate significant neuroprotection, reduced oxidative damage, and improved cognitive function with natural bioactives. Clinical trials, though limited, show promise but highlight challenges like dosing variability and bioavailability. Natural bioactive compounds represent a promising

ISBN: 978-81-980623-8-3

therapeutic avenue for NDDs, offering multi-faceted neuroprotection. Future research should focus on bioavailability enhancement, standardized formulations, and robust clinical validation to integrate these agents into mainstream treatment paradigms.

**Keywords**: Neurodegeneration, Natural Compounds, Drug delivery, Nanoparticles, Clinical Translation.

**PC-814**

**FABRICATION OF SOLID LIPID NANOPARTICLES FOR RAMIPRIL: A PROMISING STRATEGY FOR BIOAVAILABILITY ENHANCEMENT**

Allimalarkodi S, Revathi S, Sundharavel M
Department of Pharmaceutics, The Erode College of Pharmacy, Erode, Tamilnadu

Ramipril, a powerful antihypertensive medication is used to treat hypertension diseases. It has a poor bioavailability of 28-35% and a short biological half-life (2-4 hours). Thus, this work seeks to investigate Ramipril loaded solid lipid nanoparticles as a novel drug delivery system for Ramipril to improve oral bioavailability. SLN were prepared by Emulsification solvent evaporation method using Glyceryl monostearate as a lipid with Tween 80 and Span 60 as a stabilizer. The generated formulations were tested for drug content, entrapment efficiency, in-vitro drug release, particle size analysis, scanning electron microscopy, Fourier transform- infrared studies. The prepared formulations were in the nano size of about 925 nm with spherical morphology. The drug content and entrapment efficiency were found to be 9.63 mg and 91.64 % respectively. The zeta potential of formulation was found to be – 9.05 mV. The in-vitro drug release profile showed sustained release of prolonged drug release. Kinetic modelling revealed that the in-vitro drug release followed non-fickian diffusion.

**Keywords**: Ramipril, Emulsification solvent evaporation, Bioavailability, Solid lipid nanoparticles

**FORMULATION AND EVALUATION OF PRAZOSIN-LOADED FLOATING MICROSPHERES**

Dumpala Abhinaya, Anita Raj Panigrahi, Kottapalli Sai Kruthi
Department of Pharmaceutics, Raghu College of Pharmacy, Dakamarri, Visakhapatnam, Andhra Pradesh, India.

Prazosin hydrochloride, an antihypertensive drug, has a short half-life requiring frequent dosing. This study aimed to develop a gastro-retentive sustained-release system to prolong gastric residence and enhance therapeutic efficacy. Floating microspheres of prazosin were prepared using the ionotropic emulsion-gelation method with sodium alginate as the primary polymer, ethylcellulose as a stabilizer, and olive oil to aid buoyancy. The prepared microspheres (F1–F4) were dried and evaluated for percentage yield, micrometric properties, buoyancy, and in vitro drug release in simulated gastric fluid (pH 1.7, 0.1N HCl). All formulations demonstrated good flow properties and buoyancy. Among them, formulation F2 showed optimal results, with a sustained drug release of 74% over 12 hours. Drug release kinetics followed zero-order patterns and were governed by Fickian diffusion, as confirmed by the Korsmeyer–Peppas model. F2 exhibited superior sustained-release performance compared to other formulations. Alginate-based floating microspheres represent a promising gastro-retentive system for prazosin hydrochloride. Their ability to sustain drug release may reduce dosing frequency, improve patient compliance, and minimize fluctuations in blood pressure. Given the biocompatibility of sodium alginate, this delivery system is safe and well-suited for long-term antihypertensive therapy.

**PC-816**

**FORMULATION AND EVALUATION OF CURCUMIN TRANSDERMAL PATCHES FOR WOUND HEALING**

K.P.R Bavana, L.Ramanamma

The present study focused on the formulation and evaluation of curcumin-loaded transdermal patches aimed at wound healing and anti-inflammatory applications. Curcumin, a bioactive compound of turmeric, suffers from poor oral bioavailability due to low solubility and extensive first-pass metabolism. Hence, its delivery through the transdermal route offers an effective alternative by bypassing gastrointestinal degradation and providing sustained release. The patches were prepared using the solvent casting method, employing polymers such as polyvinyl pyrrolidone (PVP) and methyl cellulose, along with plasticisers and penetration enhancers.The prepared patches were evaluated for physicochemical and mechanical properties, including thickness, weight variation, folding endurance, moisture absorption/loss, surface pH, and drug content uniformity. The results revealed that the patches were smooth, uniform, yellow in colour, and free from cracks. The average weight of patches was 209.66 mg, with excellent folding endurance, showing cracks only after 356 folds. Moisture absorption was recorded at 4.16%, while surface pH remained close to neutral, ensuring skin compatibility. In vitro dissolution and ex vivo permeation studies demonstrated sustained release of curcumin, following first-order kinetics ($R^2$ = 0.9549). FTIR analysis confirmed no significant chemical interaction between curcumin and polymers, indicating stability of the formulation.Overall, the optimized formulation provided controlled release with desirable physicochemical properties and effective drug-polymer compatibility. These findings suggest that curcumin transdermal patches can be a promising therapeutic system for wound healing, pain relief, and inflammation management, thereby improving patient compliance and clinical outcomes.

**Keywords**: Curcumin, Transdermal Patches, Solvent Casting, Wound Healing, First-order Kinetics.

**FORMULATION AND EVALUATION OF FLOATING TABLETS FOR THE MANAGEMENT OF GASTRIC REFLUX**

Kamisetty Chaitanya, Putta Sanjay Kumar
Department of Pharmaceutics, VJ's College of Pharmacy, Diwancheruvu, 533296, Rajahmundry, East Godavari, AP, India.
chaitanya11365@gmail.com

The study aims to formulate the floating tablets for the management of gastric reflux from the Desmostachya bipinnata extract. The polymers HPMC K4M and Carbopol 940 are selected as the matrix forming agents. The $NaHCO_3$ was used as an effervescent agent, and magnesium stearate was used as a lubricant. The flow properties of the mixture were shown satisfactory. The tablet was prepared by direct compression method.The parameters evaluated with the results are as follows: The hardness of the tablet was 4 kg , the floating lag time is 56 seconds and the tablet's total floating time is 7 hours. The tablet followed Korsmeyer–Peppas release kinetics and the drug release was 90% within 8 hours.

**Keywords**: Reflux, Desmostachya bipinnata, Floating tablets, Korsmeyer–Peppas

**DECIPHERING THE IMPACT OF HYALURONIC ACID GRAFTING DENSITY AND MOLECULAR WEIGHT ON PACLITAXEL LIPOSOME IN CD-44 RECEPTOR TARGETING.**

Shreyas Babu BV, Mahendra Prajapati.
Department of Pharmaceutical Technology, SVKMS NMIMS, Shirpur, Maharashtra, India - 425405.
shreyasbabu002@gmail.com

The biggest challenge in developing efficacious anticancer formulations is to improve their targeting specificity and reducing toxicity. For this purpose, HA anchored paclitaxel liposomes (HA-PTX-LIP) were fabricated using synthesized conjugate HA-DSPE (HA Molecular Weight- 12, 76, and 160–200 kDa). Maximum in vitro cell targeting was observed with 160–200 kDa HA-PTX-LIP compared to 11 and 76 kDa HA PTX-LIP, indicating HA's MW-dependent HA-CD44 binding and internalization. Further, the effect of grafting density (HA/L ratio- µg HA-DSPE/µmol Lipid) of 160–200 kDa HA-DSPE on tumor targeting was evaluated in vitro at three dif ferent levels (low-20 µg/µmol, mid-50 µg/µmol, and high- 100 µg/µmol). HA/L -100 exerted the highest in vitro tumor-targeting potential. Upon in vivo evaluation, 160–200 kDa HA-PTX LIP (HA/L-100) exhibited 18.11 and 27.4-fold improved AUC and MRT, respectively, compared to the marketed formula tion. Moreover, it showed improved biodistribution with less organ AUC (liver, spleen, and kidney) when compared with the marketed formulation. A significant reduction in ROS generation suggested decreased tumor incidence. Compared to the control and marketed formulations, the modified liposome showed increased targeting potential in the in vivo antitumor efficacy on the ovarian tumor model, resulting in a 4.88 and 2.81-fold reduction in tumor volume.

ISBN: 978-81-980623-8-3

Compared to the control and commercial formulations, tumor weight was also reduced by 1.48 and 1.11-fold. Animal survival was 100 percent with 160–200 kDa HA-PTX-LIP (HA/L-100) without significant weight loss. The findings suggest the possibility of rationalizing HA's molecular weight and grafting density for efficient in vivo ovarian tumor targeting.

**Keywords**: Paclitaxel, HÀ-DSPE, Liposome, CD-44 receptor targeting, Ovarian cancer.

## FORMULATION, DEVELOPMENT AND EVALUATION OF FILM FORMING SPRAY FOR PSORIASIS

Khushi Raikwad, Rutuja Tijare, Jayshree Taksande, Nishant Awandekar, Milind Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur (MH) – 442001

Film-forming sprays (FFS) are an innovative transdermal drug delivery system that enhance patient compliance and provide sustained drug release. In this study, a film-forming spray of Curcuma longa was developed using Ethyl Cellulose and Eudragit polymers by the solvent evaporation technique. The formulations were evaluated for drug content, pH, viscosity, drying time, spray angle, stickiness, water washability, and spray volume per actuation, along with in-vitro drug diffusion and ex-vivo permeation studies. Drug release was assessed using a modified Franz diffusion cell, showing satisfactory performance in all parameters. Among the tested formulations, the Ethyl Cellulose and Eudragit (1:1) combination demonstrated the highest drug release and optimal drug content. The results indicate that Curcuma longa film-forming spray is a promising sustained release transdermal system with potential application in the treatment of psoriasis.

**Keywords**: Curcuma longa, Film-forming spray, Transdermal delivery, Solvent evaporation, Psoriasis

## STUDIES ON ENHANCEMENT OF BIOAVAILABILITY OF HIGH-POTENCY STATINS THROUGH NOVEL FORMULATION APPROACH

M.S.N. Sandhya, Jayapal Reddy Gangadi, Varun Dasari
Research Scholar, Faculty of Pharmaceutical Sciences, Motherhood University, Roorkee-Dehradun Road, Post Bhagwanpur, Roorkee, Uttarakhand-247661
sandhyamaradapu@gmail.com

High-potency statins (HPS), particularly Rosuvastatin, are potent lipid-lowering agents but suffer from poor oral bioavailability due to low aqueous solubility, extensive first-pass metabolism, and efflux transport. This study investigates whether advanced formulation strategies—specifically gastroretentive drug delivery systems (GRDDS), solid dispersions, nanoparticles, and lipid-based carriers can significantly enhance solubility, dissolution, and pharmacokinetics of HPS. Given their BCS Class II classification, dissolution rate is the primary limitation for absorption. By combining prolonged gastric retention with nanoscale engineering, these approaches are expected to improve permeability and bioavailability, thus enhancing therapeutic efficacy while minimizing dosing frequency. Formulations developed include GRDDS (floating tablets, mucoadhesive microspheres, in situ gels), solid dispersions with hydrophilic polymers (PVP, PEG, HPMC), and nanoparticles prepared by solvent evaporation and precipitation methods. Characterization was carried out through solubility and dissolution studies (USP-II), particle size and zeta potential analysis, and drug–excipient compatibility using FTIR, DSC, and PXRD. In vivo pharmacokinetic evaluations were conducted in suitable animal models to determine Cmax, Tmax, AUC, and relative bioavailability. Notably, the optimized solid dispersion formulation (SD-F6) demonstrated a 2.38-fold improvement in bioavailability compared to the marketed product and a 3.42-fold increase relative to pure drug suspension. Preliminary outcomes indicate that GRDDS provided sustained gastric retention and controlled release, while Nano systems and lipid-based carriers significantly enhanced dissolution and absorption. Optimized formulations are expected to offer improved stability, scalability, and therapeutic outcomes. These results highlight the potential of novel formulation platforms to overcome biopharmaceutical barriers of statins and translate into clinically superior, patient-friendly therapies for cardiovascular disease management.

**Keywords**: High-potency statins, Gastroretentive drug delivery systems, Nanoparticles, Solid dispersions, Bioavailability enhancement.

## DEVELOPMENT AND EVALUATION OF A MUCOADHESIVE NANOPARTICULATE DRUG DELIVERY SYSTEM FOR BRAIN TARGETING THROUGH NASAL ROUTE

Vidhya Pravin Thorat, Avinash Ramrao Tekade
Marathwada Mitra Mandal's College of Pharmacy, Thergaon (Kalewadi), Pune-411033 (M.S.), India (Affiliated to Savitribai Phule Pune University, Pune)
thorat.vidhya@gmail.com, avitekade@gmail.com

This study aims to develop and optimize Pramipexole-loaded nanostructured lipid carriers (NLCs) for effective management of Parkinson's disease via intranasal administration. Caesalpinia crista seed extract was incorporated as a natural mucoadhesive agent to enhance nasal residence time and facilitate direct nose-to-brain drug delivery, bypassing the blood-brain barrier (BBB). NLCs were formulated using solvent diffusion method, with glycerol monostearate and triglycerides as lipid matrices, and Tween 40 and Poloxamer 188 as surfactant and co-surfactant. A Box–Behnken Design was employed to optimize key formulation parameters—lipid content, surfactant concentration, and stirring speed—based on critical quality attributes such as drug content, entrapment efficiency, particle size, polydispersity index (PDI), zeta potential, and drug release. The optimized formulation (NF10) showed a drug content of 98.84 ± 0.82%, entrapment efficiency of 96.02 ± 1.38%, particle size of 215.6 ± 1.9 nm, PDI of 0.271 ± 0.92, and zeta potential of −28 ± 1.25 mV. In vitro studies demonstrated sustained drug release (94.71 ± 0.065% over 6 h). Ex vivo studies showed 91.51 ± 1.08% nasal mucosal permeation and mucoadhesive strength of 7357.5 dyne/cm². In vivo pharmacokinetic studies in rats revealed brain and plasma Cmax value 1.27289 µg/ml and 1.05289 µg/ml at Tmax of 1 and 2 h , respectively, after intranasal administration. These findings confirm enhanced brain targeting and bioavailability of Pramipexole, highlighting the potential of this mucoadhesive NLC system as a promising non-invasive therapeutic strategy for Parkinson's disease.

## DESIGN AND DEVELOPMENT OF MUCOADHESIVE BUCCAL TABLETS OF PRAVASTATIN SODIUM USING A DOE APPROACH

Arpna Indurkhya, Prashant Sharma
Sri Aurobindo Institute of Pharmacy, Indore (M. P.), India, 453555
arpna.indurkhya@saip.ac.in

This study aimed to develop mucoadhesive buccal tablets of Pravastatin Sodium using a Quality by Design (QbD) framework with a Box-Behnken Design. Pravastatin Sodium, limited by poor bioavailability from first-pass metabolism, was formulated for buccal delivery to improve absorption and provide sustained release. Chitosan, HPMC K4M, and Xanthan Gum were selected as key polymers, with mucoadhesive strength and 12-hour cumulative drug release as the primary response parameters. Thirteen formulations were prepared by direct compression and evaluated for pre- and post-compression parameters, all within pharmacopoeial limits. Polymer concentrations significantly affected swelling, adhesion, and release. In vitro studies showed that Chitosan increased drug release, while HPMC prolonged it. The optimized formulation containing Chitosan (37 mg), HPMC K4M (15 mg), and Xanthan Gum (22 mg) released ~85% of the drug over 12 h with good mucoadhesive properties. Release followed first-order kinetics ($r^2$ = 0.992) and Korsmeyer-Peppas model ($r^2$ = 0.983), indicating non-Fickian transport. Response surface methodology confirmed the significant influence of polymers, with close agreement between predicted and observed results. FTIR and DSC confirmed drug–polymer compatibility, while ICH stability studies showed six-month robustness. The findings highlight buccal mucoadhesive delivery of Pravastatin Sodium as a viable alternative to oral therapy, ensuring sustained release, reduced dosing frequency, and improved patient compliance.

**Keywords**: Mucoadhesive buccal tablet, Pravastatin Sodium, DoE, Box-Behnken Design (BBD), Antihyperlipidemic.

**FORMULATION AND EVALUATION OF ECONAZOLE NITRATE NANOEMULGEL: AN INNOVATIVE STRATEGY FOR IMPROVED TOPICAL ANTIFUNGAL DELIVERY**

Sowmya.S, Selvaraju

Econazole nitrate is a broad-spectrum antifungal drug used in the treatment of superficial fungal infections. However, its therapeutic efficacy is limited by poor aqueous solubility and reduced skin penetration. This study aims to design, optimize, and evaluate an econazole nitrate-loaded nanoemulgel formulation to enhance solubility, skin permeation, and antifungal effectiveness. Econazole-loaded nanoemulsions were prepared using the aqueous titration method with Oleic acid as the oil phase, Tween 80 as surfactant, and PEG 400 as co-surfactant, followed by ultrasonication. Different Smix ratios were employed to construct a pseudo-ternary phase diagram and identify the nanoemulsion region. The optimized nanoemulsion was incorporated into a Carbopol 934 gel base to form a nanoemulgel. The formulations were evaluated for globule size, polydispersity index (PDI), zeta potential, entrapment efficiency, pH, viscosity, spreadability, in vitro drug release, ex-vivo diffusion, and antifungal activity. FTIR analysis confirmed no significant drug–excipient interactions. The optimized formulation exhibited small globule size, narrow PDI, and stable zeta potential, indicating stability. Incorporation into the gel base resulted in desirable viscosity, pH, and spreadability for topical application. In vitro and ex vivo studies revealed enhanced drug release and skin permeation compared to plain econazole gel. Kinetic modeling indicated non-Fickian diffusion as the release mechanism. Antifungal studies confirmed improved efficacy against Candida albicans. The developed econazole nitrate nanoemulgel demonstrated improved solubility, skin penetration, and antifungal activity, offering a promising alternative to conventional topical formulations. The nanoemulgel system can enhance patient compliance and therapeutic effectiveness by providing sustained drug release and superior permeation characteristics.

**Keywords**: Econazole nitrate; Nanoemulgel; Pseudo-ternary phase diagram; Ultrasonication; Antifungal therapy; Drug release; Permeation.

**DEVELOPMENT AND EVALUATION OF DIPHENHYDRAMINE HCL TRANSDERMAL PATCH USING FACTORIAL DESIGN APPROACH**

Desai Avni P, Himanshu Solanki
Department of Pharmaceutics, SSR College of Pharmacy, Sayli, Silvassa, Dadra & Nagar Haveli, India - 369230.
Avnidesai1308@gmail.com

This study presents the development of a novel transdermal patch of Diphenhydramine HCl using hydroxypropyl methylcellulose (HPMC K100M) as the matrix polymer to address limitations of conventional oral formulations such as first-pass metabolism, frequent dosing, and variable patient compliance. Transdermal delivery was selected as a patient-friendly approach to achieve sustained and controlled release. A Quality by Design (QbD) strategy was employed to define the Quality Target Product Profile (QTPP), identify critical formulation variables, and establish a robust design space, ensuring product quality is built into the process rather than tested at the end. Patches were fabricated by solvent casting, with HPMC K100M as film former and PEG 400 as plasticizer. Preliminary trials aided in identifying key formulation parameters, which were subsequently optimized using a three-level factorial design. The developed patches were evaluated for thickness, weight uniformity, surface pH, drug content, mechanical integrity, in vitro diffusion profile, and stability under storage conditions. The optimized formulation demonstrated desirable mechanical strength, uniform drug distribution, and a controlled release profile over an extended duration, highlighting its potential as a safe and effective alternative to oral Diphenhydramine therapy. This work not only establishes a promising transdermal platform for Diphenhydramine delivery but also illustrates the value of QbD-driven formulation development in advancing next-generation drug delivery systems.

**RECENT ADVANCEMENTS AND FUTURE DIRECTIONS OF NANOCOSMETICS**

Sakshi Raut, Domeshwari Rahangdale, Shyam W. Rangari, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy Kamptee, Nagpur, Maharashtra-441002

The convergence of nanotechnology and the clean beauty movement has catalyzed the development of sustainable nanocosmetics that maintain efficacy while addressing environmental and safety concerns. This paradigm shift represents a fundamental transformation from first-generation persistent nanomaterials to biodegradable, bio-based systems integrated with circular economy principles. This comprehensive review examines the molecular timeline of nanocosmetics evolution, focusing on sustainable synthesis methods, environmental fate, regulatory frameworks, and emerging technologies that define the future of clean beauty nanotechnology. A systematic analysis of peer-reviewed literature from 2010-2024 was conducted, encompassing sustainable nanomaterial synthesis, environmental impact assessment, regulatory developments, and market trends in clean beauty applications. The transition toward sustainable nano-cosmetics demonstrates significant progress in green synthesis methods, with bio-based nanomaterials showing comparable or superior performance to conventional alternatives while offering enhanced biodegradability and reduced environmental impact. Advanced characterization techniques and predictive modeling enable comprehensive safety assessment, while regulatory frameworks increasingly accommodate sustainable nanotechnology innovations. The future of nano-cosmetics lies in biomimetic design, circular economy integration, and personalized formulations that leverage artificial intelligence and biotechnology advances while maintaining absolute commitment to environmental stewardship and consumer safety.

**Keywords**: Sustainable nanotechnology, clean beauty, green synthesis, biodegradable nanomaterials, circular economy, environmental safety.

**TACROLIMUS-LOADED POLYMERIC MICRONEEDLES: DESIGN, FABRICATION, AND CHARACTERIZATION**

Rachitha S V, Preeti Karwa, Ayesha Syed
Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bangalore, Karnataka, India - 560027
rachithasv04reddy@gmail.com

Tacrolimus, a BCS class II immunosuppressive drug, is characterized by a narrow therapeutic index and poor oral bioavailability due to P-glycoprotein efflux and extensive pre-systemic metabolism, which further contributes to neurotoxicity and nephrotoxicity when administered orally. To address these limitations, the current study focus on the design and development of a polymeric microneedle (PMN) system for transdermal delivery of Tacrolimus, aiming to bypass first-pass metabolism, provide painless administration, and achieve controlled release for improved patient compliance. The PMNs were fabricated using solvent casting method by in house prepared bees wax mold rather than conventional polydimethylsiloxane (PDMS) mold, and a Central Composite Design was employed to optimize the concentrations of Polyvinylpyrrolidone (PVP) K90 and Eudragit RS100 (independent variables), evaluating their influence on mechanical strength and tensile strength (dependent variables). The optimized formulation exhibited superior mechanical strength (8.07 N) and tensile strength (1.484 MPa). Characterization studies, including weight variation, swelling index, optical and scanning electron microscopy, FTIR, DSC, drug content, in-vitro diffusion, release kinetics, and stability analysis, confirmed the robustness of the formulation. Microscopy revealed well-formed microneedles with an average length of 470.79 µm, base width of 156.33 µm, and pitch distance of 709.33 µm. The optimized PMN patch demonstrated a drug content of 97.49 ± 0.55% and sustained release of 79.79 ± 0.10% over 30 hours, following zero-order diffusion-controlled kinetics. These findings indicate that polymeric microneedles of Tacrolimus can effectively enhance bioavailability, maintain therapeutic drug levels, minimize oral delivery-related toxicities, establishing PMNs as a promising patient-centric strategy for immunosuppressive therapy.

**DESIGN, DEVELOPMENT AND CHARACTERISATION OF SPRAY-DRIED POWDER OF POMEGRANATE FOR NUTRITIONAL BENEFITS**

Mitesh P. Sonawane, Avish D. Maru
Department of Pharmaceutics, SNJB's SSDJ College of Pharmacy, Chandwad, Nashik, Maharashtra, India – 423101
sonawanemitesh1919@gmail.com

It has been noted that certain natural compounds have a vast array of nutritional benefits; however, many of these values may be lost or destroyed because they are not transformed into a product that contains all of the nutritional and therapeutic benefits that were initially contained in the raw plant material. Pomegranate spray-dried powder was created in order to solve this issue in the current study. The goal of the study is to create a spray-dried pomegranate powder, analyze spray-drying parameters such air inlet temperature and maltodextrin concentration, and track variables like yield, moisture content, hygroscopicity, bulk density, and solubility time. The current investigation used temperature conditions between 130 and 150 °C with polymer concentrations of 5%, 15%, and 25% w/v. It was found that the maximum yield (57%), lower moisture content (1.8%), lower hygroscopicity (i.e., 0.72 gm of water absorb / 100 gm of powder), higher bulk density (0.64 gm/ml), and longer solubility time (132 sec) are achieved at an air inlet temperature of 150 °C and a polymer concentration of 25%. Since there are no significant changes in the IR graphs of the medication and mixture with polymer, the IR analysis provides insight into the compatibility of both materials. The material's particle size was determined to be 5.7 +0.159 µm. Pomegranate powder's SEM revealed that its particles range in size from 4.5 to 6.0 µm and have an uneven shape. To sum up, research helps to enhance the nutritional and therapeutic advantages.

**Keywords**: Pomegranate, Spray drying, Maltodextrin, Nutritional value, Air inlet temperature.

**OPTIMIZATION OF ANTIOXIDANT, ANTIMICROBIAL AND TOTAL PHENOLS OF DRIED ROOTS OF LEEA MACROPHYLA ROXB. USING RESPONSE SURFACE METHODOLOGY**

KOTA PADMAJA

This article demonstrates the statistical optimization of extract of tuberous traditional roots of Leea macrophyla (family: Leeaceae) using four different variables including time, temperature, solvent and solvent solid ratio in three levels and 29 runs were designed using Box Behnken experimental design to identify the significant variables effecting DPPH Scavenging capacity, antimicrobial and total phenolic content. Response surface methodology (RSM) was used to optimize the conditions for the above-mentioned activities using four independent variables: time (20, 40, 60 min), temperature (40, 60, 80°C), solvent (ethanol, methanol and water), solvent solid ratio (10, 20, 30gm). The collective effect of different factors of these three variables shows optimum conditions for the most critical variables that exhibits significant variation in the response of interest were identified with a target to achieve maximum extraction yield at specific time, temperature, type of solvent, and ratio of the drug powder taken, shows maximum DPPH Scavenging capacity, total phenolic content (TPC) and antimicrobial activity. The result showed that at 60 min, 80°C, in water and 30gm of solid shows maximum antioxidant potential ranging from 43.52- 94.25%, TPC 44.07-104.47-9.24-12.21 mg GAE/g, the zone of inhibition 10-22.66 mm. These optimized conditions can be applied for quick extraction and efficient results of various activities, represents an improvement over existing methods.

**Keywords**: Leea macrophyla; optimization; Box Behnken method; Response surface methodology; DPPH Scavenging capacity, total phenolic content, antimicrobial activity.

**A STUDY ON COMPARATIVE PHARMACOPEIAL EVALUATION OF GENERIC AND BRANDED PARACETAMOL 500 MG TABLETS IN THE PAMPADY REGION, THRISSUR, KERALA**

Rohini T G, Deepa T Vasudevan
Department of Pharmaceutics, Nehru College of Pharmacy, Thrissur, Kerala, India-680588
rohinigopi18@gmail.com

Paracetamol (acetaminophen) is a widely used analgesic and antipyretic agent, available in both branded and generic formulations. Concerns regarding the quality, safety, and interchangeability of these formulations often arise. This study aimed to comparatively evaluate the pharmacopeial quality of branded and generic paracetamol 500 mg tablets available in the Pampady region, Thrissur, Kerala, according to Indian Pharmacopoeia (IP) specifications. Six different brands, comprising both generic and branded formulations, were collected from local pharmacies and analyzed. Quality control parameters assessed included weight variation, hardness, friability, disintegration time, dissolution profile, and assay of active pharmaceutical ingredient (API). All brands complied with IP requirements for weight variation, friability, and hardness, indicating satisfactory physical and mechanical properties. Disintegration times were within 15 minutes for all samples, confirming rapid disintegration. Dissolution testing showed more than 80% drug release within 30 minutes, meeting pharmacopeial standards. Assay results confirmed API content ranged between 96% and 103% of the labeled claim, within the acceptable range of 95–105%. Minor variations in hardness and dissolution were observed but were not statistically significant. Cost comparison revealed that a branded paracetamol strip (30 tablets) costs ₹30, while the generic version costs ₹21, reflecting a 30% cost saving. The study concludes that both branded and generic paracetamol 500 mg tablets in the Pampady region meet pharmacopeial quality standards and are therapeutically equivalent. These findings support the rational use of generic formulations as cost-effective alternatives without compromising efficacy or safety. Continuous post-marketing surveillance is recommended to maintain consistent quality.

**PC-830**

**QUALITY BY DESIGN-BASED DEVELOPMENT AND OPTIMIZATION OF VALSARTAN SUBLINGUAL TABLETS FOR ENHANCED THERAPEUTIC PERFORMANCE IN HEART FAILURE**

Naveen K Choudhary, Deepak Joshi
Professor, Mandsaur Institute of Pharmacy, Mandsaur University

Heart failure management often requires rapid therapeutic intervention, and Valsartan, an angiotensin II receptor blocker, plays a vital role in reducing cardiovascular risks. However, conventional oral administration suffers from delayed onset and reduced bioavailability due to first-pass metabolism. Sublingual delivery provides a promising alternative, ensuring faster absorption and improved patient outcomes. The present research aimed to formulate and optimize a fast-dissolving sublingual tablet of Valsartan using the Quality by Design (QbD) framework. A Box–Behnken Design (17 runs) was applied to systematically study the influence of superdisintegrants—Sodium Starch Glycolate (SSG), Crospovidone (CP), and Crosscarmellose Sodium (CCS)—on critical quality attributes, namely disintegration time and drug release. The optimized formulation (OVSF-18) demonstrated excellent pre-compression and post-compression properties, including good flowability, uniformity of weight, acceptable hardness, and low friability. In vitro evaluation revealed rapid disintegration with a cumulative drug release of 93% within 15 minutes, significantly higher than conventional formulations. Stability studies further confirmed the robustness of the optimized batch without notable degradation. This study highlights the successful application of QbD in designing a stable, effective, and patient-compliant Valsartan sublingual formulation. The developed dosage form holds strong potential to enhance therapeutic efficiency, reduce hospitalization risks, and improve overall quality of life in hypertensive and heart failure patients.

**Keywords**: Valsartan, Sublingual Tablet, Quality by Design, Box-Behnken Design, Drug Release, Hypertension, Heart Failure

**FORMULATION AND EVALUATION OF DOMPERIDONE SUSPENSION USING ITS HYDROTROPIC DISPERSIONS**

Thotapalli Koushik, K. Ramadevi
Department of Pharmaceutics, Raghu College of Pharmacy, Dakamarri, Visakhapatnam, Andhra Pradesh, India.

Domperidone is a dopamine D2 receptor antagonist widely prescribed for the management of nausea, vomiting, and gastrointestinal disorders. Despite its therapeutic benefits, Domperidone suffers from very low

ISBN: 978-81-980623-8-3

aqueous solubility, which results in poor dissolution and variable bioavailability. Conventional suspension formulations often fail to provide consistent drug release, thereby affecting clinical outcomes. To address this limitation, hydrotropic solubilization has emerged as a novel and cost-effective strategy to enhance the solubility of poorly water-soluble drugs. The present study was designed to formulate and evaluate Domperidone suspension using its hydrotropic dispersions. Hydrotropic agents such as citric acid, sodium salicylate, urea, PABA, caffeine, and resorcinol were carefully screened, and optimized dispersions of Domperidone were prepared using the solvent evaporation method. These dispersions were incorporated into suspension formulations and evaluated for various physicochemical and performance parameters, including appearance, pH, sedimentation volume, viscosity, redispersibility, drug content uniformity, FTIR, and DSC. Comparative in vitro dissolution studies were conducted between the hydrotropic suspension and a conventional Domperidone suspension. The application of hydrotropic solubilization in suspension formulation provides a simple, safe, and economical approach for improving the solubility, dissolution, and ultimately the therapeutic performance of Domperidone. This approach holds potential for extending to other Biopharmaceutics Classification System (BCS) class II drugs with poor water solubility.

**Keywords**: Domperidone, Suspension, Hydrotropic Dispersions

## GLABRIDIN-ENCAPSULATED LIPOSOME INCORPORATED HYDROGEL FOR DIABETIC WOUND HEALING

M. Gover Antoniraj, Swati Yadav, Anirban Pal
CSIR-Central Institute of Medicinal and Aromatic Plants, Lucknow, UP, 226015
gover.anto@gmail.com

In this research, glabridin-encapsulated liposome was formulated to improve the physicochemical properties of the phytomolecule for enhanced diabetic wound healing activity. The formulated liposome was incorporated into hydrogel, which was synthesised using O-carboxy methyl chitosan and oxidized alginate by imine bond formation. The polymeric intermediate and conjugated polymer were characterised by FTIR and 1H NMR analysis, which confirmed the conjugation of both polymers by specific peaks related to each polymer backbone and substituted functional group protons. The dynamic light scattering analysis revealed a particle size of liposome less than 200 nm, zeta potential greater than -25 mV, and polydispersity index 0.35, indicating the stability of the liposome. Additionally, the stability of the liposome was assessed over 90 days by measuring its size, and the results indicated that slight change in size, confirming the liposome's stability. In-vitro release study demonstrated sustained release of the phytomolecule, which releases 78% of molecules at 48 h. Cell viability of liposome-incorporated hydrogel was studied in HaCaT and L929 cell lines, and the result indicates the compatibility of the delivery system. Antimicrobial assay exhibited that the liposome inhibited S. aureus and E.coli significantly. The formulation showed inhibition of inflammatory mediators, TFN-α and IL-6. Diabetic wound was created on Swiss albino mice, which were then treated with liposome-incorporated hydrogel. The study showed that glabridin liposome was more effective in healing diabetic wounds compared to clinically available antimicrobial ointment and hydrogel formulation without phytomolecule. This research aims to further investigate the delivery system in other animal models to confirm its effectiveness in treating diabetic wounds.

**Keywords**: Glabridin, liposome, diabetic wound, hydrogel, antimicrobial

## POLYMERIC NANOPARTICLES: A MODERN APPROACH TO SKIN BRIGHTENING

Sakshi A. Sambhare, Swati N. Lade, Milind J. Umekar
Smt. Kishoritai Bhoyar college of Pharmacy, Kamptee, Nagpur, Maharashtra, India- 441002
Sakshisambhare@gmail.com

Nanotechnology contributes significantly to the advancement of cosmeceutical formulation by enhancing the active compounds' solubility, stability, safety, loading efficiency, and skin permeability. Often empolyed brightening agents like vitamin C, arbutin, and kojic acid are unstable, degrade quickly, and have limited topical efficacy.The primary benefit of using polymeric nanoparticles lies in their ability to entrap active agents regardless of their solubility whether hydrophilic or lipophilic. Polymeric nanoparticles are small, solid particles composed of synthetic or natural polymers that serve as delivery systems for bioactive compounds, medications, and cosmetics. Modern delivery methods such as polymeric nanoparticles have become popular because they provide skin-brightening agents with controlled release, increased stability, and improved dermal penetration. To create nanoparticles, biodegradable polymers like chitosan, PLGA, and alginate are used in solvent evaporation, ionic gelation, and nanoprecipitation processes. Polymeric nanoparticles offer a revolutionary method of skin brightening by fusing safety and effectiveness.

**Keywords**: Polymeric nanoparticles, Chitosan, cosmeceutical

## GREEN APPROACHES TO NANOCOSMECEUTICALS: AN OVERVIEW

Mahima S. Chaudhari, Swati N. Lade, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, India- 441002

Eco-friendly green nanoformulations provide a safer and more biocompatible option compared to chemical-based nanoformulations in the cosmetics industry. In contrast to traditional cosmetic formulations, this overview highlights how cosmeceuticals that investigate nanotechnology-based systems for the delivery of natural polymers can enhance product performance.The active ingredients in traditional cosmeceuticals frequently have low bioavailability, poor stability, and restricted penetration. Therefore shortcomings of conventional dosage systems, addressed by natural polymer-based biocompatible nanocarriers.Incorporating natural polymers like chitosan, alginate, cellulose, and silk fibroin into nanocarrier development offers safe, renewable, and biodegradable platforms.They also improve functionality of nanocarriers by using environmentally friendly techniques like emulsification, ionic gelation.For instance, ionic crosslinked chitosan nanoparticles with tripolyphosphate provide mucoadhesion and controlled release of bioactive substances, while calcium-ion-crosslinked alginate nanocapsules protect hydrophobic materials within an oil core.Active cosmeticeutical ingredients can be delivered more precisely, penetrate the skin more effectively, enable targeted and sustained release and have better bioavailability. Nanocarriers such as nanoparticles, nanogels, and nanoemulsions make it possible to effectively encapsulate both hydrophilic and hydrophobic bioactive compounds.This encapsulation extends the shelf life of the active ingredients by shielding them from oxidation, heat, and light.Therefore, natural polymer-based nanocarriers in cosmeceuticals, highlight the potential of green nanotechnology in future cosmetic science by providing a promising balance between safety, efficacy, and environmental stewardship.

**Keywords**: Nanocosmeceuticals, Natural polymers, Nanocarrier.

## SMART CONTACT LENSES: A NOVAL PLATFORM FOR SUSTAIN SMART CONTACT LENSES OPHTHALAMIC DRUG DELIVERY SYSTEM AND OCULAR MONITORING

M.Sai kumari, M.Divya, M.Gnaneswari, K.Atchuta kumar
Bhaskara Institute of Pharmacy, Komatipalli village, Bobbili, Affiliated by Andhra University, Visakhapatnam India - 535558.

Conventional ophthalmic drug delivery system such as eye drops and ointments are limited by poor bioavailability, rapid tear clearance, and low patient compliance, resulting in therapeutic in efficiency. To overcome these challenges, smart contact lenses have emerged as a novel platform for sustained and control ocular drug delivery. These lenses are fabricated from hydro gel polymers are silicon material and can be engineered to incorporate drugs through methods such as soaking, nanoparticle embedding, micro- reservoir integration, and layer by layer coating. Recent advancement have introduced stimuli-responsive systems in which drug release can be triggered by external cues including light, heat or electrical signals. Smart lenses can deliver a wide range of therapeutic agent including, anti-glaucoma medication ( timolol , letanoprost), a anti inflammatory agents(dexamethasone, keterolac), antibiotic and anti allergic drugs ,there by enhancing treatment outcomes in various ocular diseases. Compared to conventional methods, these devices provide prolonged residence time,

ISBN: 978-81-980623-8-3

improved bioavailability reduce dosing frequency and added benefit of simultaneous vision correction. Furthermore, integration of biosensors enables real time monitoring of intraocular pressure, glucose levels or other ocular biomarkers, expanding their role in personalized medicine. Despite significant advantages, challenges remain in terms of biocompatibility, oxygen permeability, risk of burst release and regulatory approval.

**Keywords**: Smart contact lenses, Ocular drug delivery, Glaucoma, Sustained release, Biosensors.

**PC-836**

**FORMULATION AND EVALUATION OF TOLNAFTATE LOADED CHITOSAN NANOPARTICLE EMULGEL**

Aiswarya K, S. Mahendran
Department of Pharmaceutics, Nehru College of Pharmacy, Thrissur, Kerala, India-680588
aiswaryamanoharan89@gmail.com

Tolnaftate is a synthetic thiocarbamate drug used as an antifungal agent that acts by inhibiting fungal squalene epoxidase. The drug alters hyphae and inhibits mycelial growth in fungi. This medication is used topically to treat fungal infections such as jock itch, athlete's foot, tinea cruris, and tinea corporis. Tolnaftate comes under the BCS IV class of drugs, which possess poor water solubility and high hydrophobicity, leading to low permeability and side effects such as itching, dryness, or peeling of the treated skin. Hence, for the enhancement of solubility and to reduce the local side effects, tolnaftate loaded with chitosan nanoparticles appeared to be a viable approach. Chitosan is a polysaccharide derived from the deacetylation of naturally occurring chitin. It is biocompatible, biodegradable, nontoxic, water soluble and requires very less use of solvents for preparation. Emulgel for topical use overcomes the delivery of hydrophobic drugs and offers dual controlled release effect. Thus, tolnaftate-loaded chitosan nanoparticles emulgel with penetration enhancers by ionic gelation method increases the solubility, permeability and reduces side effects of drug. Nanoparticles were prepared, and their preformulation study was conducted. The optimized nanoparticles were characterised by FTIR, SEM, entrapment efficiency, and drug release study. The anti-fungal activity of tolnaftate-loaded chitosan nanoparticles was evaluated for 4 formulations, which all showed good results. Further, by using formulation 3, the nanoparticle emulgel was formulated and evaluated for appearance, viscosity, pH, spreadability, in vitro release, and antifungal activity. The formulated emulgel showed better antifungal activity than the marketed formulation.

**PC-837**

**MANGIFERIN NANOEMULGEL: A NOVEL PHYTOPHARMACEUTICAL APPROACH FOR ENHANCED DERMAL DELIVERY**

Shashank R, Ayesha Syed, Preeti Karwa
Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bengaluru
rajushashank2002@gmail.com

Mangiferin is a potent bioactive antioxidant and has been demonstrated to possess numerous biological activities including anti-inflammatory, antidiabetic, anticancer, antimicrobial, analgesic, and immunomodulatory properties. However, its clinical translation is restricted due to poor solubility, limited mucosal permeability, and low bioavailability. To address these challenges, a nanoemulsion-based formulation of Mangiferin was developed to enhance solubility and permeability, followed by incorporation into a nanoemulgel for sustained topical delivery. Nanoemulsions were prepared using oleic acid, Tween 80, and Transcutol P (Smix ratio) by the classical titration method, with pseudoternary phase diagrams constructed for optimization. Response Surface Methodology (RSM) was applied to optimize the formulation based on particle size and polydispersity index (PDI). Among the tested formulations, F2 demonstrated optimum characteristics with particle size 354.0 nm and PDI 0.285, and was further evaluated for pH, viscosity, and in vitro drug release. F2 was incorporated into a Carbopol-based hydrogel (0.5–2%) to produce the optimized Mangiferin nanoemulgel (F2G). The developed nanoemulgel showed desirable physicochemical properties including appropriate pH, excellent spreadability, and extrudability, with a cumulative drug release of 85.52% at 24 hours, indicating sustained release. Mangiferin-loaded nanoemulgel shows great potential as a topical system by enhancing solubility, permeability, and therapeutic effectiveness, while providing sustained release for better patient compliance.

**Keywords**: Mangiferin, nanoemulsion, nanoemulgel, pseudoternary phase diagram.

**PC-838**

**INTEGRATION OF DIOVAN WITH PROTEUS CHIP TECHNOLOGY:A NOVEL APPROACH IN CARDIOVASCULAR THERAPY**

Niya Catherine Binoy, Arshita Kumari, Swarangi Karangale, Sunil Kumar Dwivedi
Department of Pharmacology, Sri Aurobindo Institue of Pharmacy, Indore, MP-453555
niyacatherine.binoy@saip.ac.in

The combination of pharmaceuticals with innovative digital technologies has heralded a new era in healthcare, offering unprecedented opportunities for personalized medicine and improved patient outcomes. In this context, the integration of Diovan (Valsartan), an angiotensin II receptor blocker commonly used in the management of hypertension and heart failure, with Proteus Chip Technology represents a groundbreaking advancement. The Proteus Chip, a miniaturized ingestible sensor, is designed to be embedded within pharmaceutical formulations, enabling real-time monitoring of medication adherence and physiological responses within the body. The data from the study conducted by Novartis using Proteus' "chip in the pill" technology to monitor patient compliance with Diovan, a blood pressure medication, showed a notable increase in compliance rates. Before using the technology, patient compliance was at 30%, but after six months of utilizing the technology, compliance increased more than two-fold to 80%. This suggests that this technology can significantly improve patient medication adherence for controlling blood pressure. It utilizes an alkaline charge generated by the gastric juices to activate a chip embedded in the medication, which is detected by a receiver, then transmits the data to a sensing patch worn on the patient's skin. Additionally, the technology provides data on physiological parameters such as heart rate, activity levels, medication effectiveness, and respiration patterns, which can be accessed and analysed by caregivers to optimize treatment outcomes.

**Keywords**: Diovan, Proteus Chip Technology, Medication Adherence.

**PC-839**

**BIOANALYTICAL METHOD DEVELOPMENT AND VALIDATION FOR ESTIMATION OF DIMENHYDRINATE IN HUMAN PLASMA**

Prajakta D. Gaikwad, Samruddhi T. Torane, G. K. Dyade
Dept of Postgraduate Studies in Pharmacy, SVPM'S College of Pharmacy, Malegaon (BKII)
Baramati Dist Pune 413115 India

Objective of regulatory guidelines viz. US FDA and ICH M 10 are intended to provide recommendations for the validation of bio analytical assays for chemical and biological drug quantification and their application in the analysis of study samples. Bio analytical method was developed for estimation of dimenhydrinate in human plasma by chromatographic technique. Bio analytical method was developed for estimation of dimenhydrinate DMH, with RP-HPLC, using RP-C18 column equipped with UV detector. The mobile phase [methanol: acetate buffer pH 4.0 (pH adjusted with acetic acid)] was pumped at a flow rate of 0.8 ml/min in the ratio of 76:24 % v/v and the eluent was monitored at wavelength 276 nm. The method was studied for quantitative estimation of drug from human plasma. The drug dimenhydrinate was shown linear response in conc range (1000-7000 ng/ml) in plasma. Accuracy and precision study shown that % CV was varied in the range (3.541-6.942) for DMH at all conc. levels and; the data of % nominal conc. was varied between (94.15-92.17) for DMH at all conc. levels. Guideline elaborated that the results of pivotal nonclinical toxicokinetic (TK)/pharmacokinetic (PK) studies and of clinical trials, including comparative bioavailability / bioequivalence (BA/BE) studies, are used to make regulatory decisions regarding the safety and efficacy of drug products. The developed method can be applied for relative bioavailability and bioequivalence study of drug or/and dosage form.

**DESIGN AND IN-VITRO EVALUATION OF GASTRO RETENTIVE MICRO-BALLOONS OF ACYCLOVIR BY USING COMBINATION OF HYDROPHILIC AND HYDROPHOBIC POLYMERS**

Prathibha CV, Shivanand K Mutta, Manjula R
Department of Pharmaceutics, Oxbridge College of Pharmacy, Bangalore, India 560091
Prathibhacv7@gmail.com

The present research focused on formulating Acyclovir loaded gastro-retentive micro-balloons to prolong the drug's gastric residence and enable controlled release. The floating microspheres were produced via a non-aqueous solvent evaporation method, using Hydroxypropyl Methylcellulose (HPMC K4M) and Ethyl Cellulose (EC) in varying ratios across nine different formulations. These micro-balloons were systematically evaluated for particle size, surface characteristics through scanning electron microscopy (SEM), and additional physical properties such as morphology and flow behavior. Key parameters including percentage production yield, entrapment efficiency, floatation time, and in vitro release performance were also assessed. The micro-balloons were found to be spherical and exhibited consistent particle sizes ranging between 167.5 and 180.8 µm, making them well-suited for oral delivery. Drug entrapment efficiency was observed in the range of 75.37% to 89.24%, depending on polymer composition. SEM analysis and size distribution data highlighted noticeable differences among batches. Formulations F2, F3, and F6 those with a higher content of EC showed prolonged buoyancy over 12 hours and were effective in extending drug release. These outcomes emphasize the importance of optimizing polymer blends to achieve desirable floating behavior and sustained-release profiles for Acyclovir.

**Keywords**: Gastro retentive drug delivery system, Acyclovir micro balloons, non-aqueous solvent evaporation, Particle Size, Buoyancy, HPMC K4M, EC.

**FORMULATION AND EVALUATION OF NADIFLOXCIN TOPICAL GEL USING MIXED SOLVENCY CONCEPT**

Shubhangi Gupta, Ritika Chhajed, Shreya Katara, Mahendra Patel, Arpna Indurkhya
Sri Aurobindo Institute of Pharmacy, Indore (M. P.), India, 453555
shubhangi.guptaphd2024@saip.ac.in

The present study explored the application of the mixed solvency technique for the formulation of aqueous topical gels of poorly water-soluble drugs, with Nadifloxacin selected as the model drug. Mixed solvency reduces the required concentration of individual solubilizers, thereby minimizing toxicity while achieving significant solubility enhancement. Nadifloxacin samples were characterized by physical appearance, melting point, FTIR, and UV spectroscopy, confirming purity and suitability for formulation development. Spectrophotometric studies revealed no interference of the selected solubilizers in the estimation of Nadifloxacin. Among various solubilizing blends, on the basis of solubility enhancement more than 70 times in Blend B containing Sodium benzoate 20%, sodium caprylate 20%, propylene glycol 10% was chosen for gel formulation. Gels were prepared using Carbopol 934 as the gelling agent, which demonstrated good clarity, homogeneity, and favorable organoleptic properties. Formulated gels were evaluated for viscosity, spreadability, washability, skin irritation, pH, content uniformity, and in vitro release. The optimized batch (F2) showed content uniformity of 98.8±0.21% and drug release of 94.84% within 420 minutes. Stability studies confirmed retention of more than 98% drug content after one month, indicating good chemical stability. The findings demonstrate that Nadifloxacin topical gels prepared by mixed solvency are stable, effective, and safe for acne treatment. This approach provides an economical and scalable strategy for developing aqueous formulations of poorly water-soluble drugs using physiologically compatible solubilizers, thereby enhancing therapeutic outcomes and patient compliance.

**Keywords**: Mixed solvency, Nadifloxacin, Poorly water-soluble drugs, Topical gel

**PC-842**

**A COMPREHENSIVE EVALUATION OF ADVERSE DRUG REACTIONS LINKED TO AMINO ACID PRESCRIPTIONS IN A TERTIARY CARE HOSPITAL**

Megha Tiwari, Anu Hardenia, Seemu Singh, Nafia Rahman, Sourabh Gour
Sri Aurobindo Institute of Pharmacy, Indore, Madhya Pradesh
megha.tiwariphd2023@saip.ac.in

Adverse drug reactions (ADRs) pose significant challenges in patient care, particularly in tertiary care settings where complex treatments are administered. Amino acid prescriptions are common in such settings, yet their potential for adverse reactions is not extensively studied. This research aims to comprehensively investigate ADRs associated with amino acid prescriptions in a tertiary care hospital. A retrospective analysis of patient records was conducted to identify cases where amino acid prescriptions were implicated in adverse reactions. Data regarding the types of reactions, severity, patient demographics, and concurrent medications were collected and analysed. The investigation spanned a defined period within the hospital's database. The analysis revealed a spectrum of adverse reactions linked to amino acid prescriptions. These reactions varied in severity, ranging from mild to severe. The most commonly reported reactions included gastrointestinal disturbances, allergic reactions, and metabolic imbalances. Certain patient demographics and concurrent medication use were found to influence the likelihood and severity of ADRs. This study underscores the importance of vigilance in monitoring and managing adverse reactions associated with amino acid prescriptions in tertiary care settings. The findings highlight the need for further research and strategies to mitigate the risks of ADRs while optimizing patient care and treatment outcomes in this specific context. Such insights can inform healthcare professionals in their decision-making processes and contribute to enhancing the safety and effectiveness of amino acid therapy in clinical practice.

**Keywords**: ADR's, Amino Acid, Vigilance, Patient care, Safety & efficacy

**NEXT-GENERATION DRUG DELIVERY: THE ROLE OF ARTIFICIAL INTELLIGENCE**

CHAITANYA BOBDE

The integration of Artificial Intelligence (AI) into drug delivery research is rapidly transforming the landscape of pharmaceutical science and personalized medicine. This emerging synergy enables the development of highly precise, efficient, and targeted therapeutic systems, ushering in a new era of next-generation drug delivery. AI algorithms, particularly machine learning and deep learning, are being utilized to optimize drug formulation, predict pharmacokinetic and pharmacodynamic behaviors, and design intelligent delivery platforms such as responsive nanocarriers and implantable devices. Moreover, AI facilitates the real-time analysis of vast biomedical datasets, enabling researchers to tailor treatments based on patient-specific parameters and disease profiles. From improving drug solubility and stability to enhancing site-specific targeting, the application of AI is significantly accelerating the development pipeline while reducing time and cost. This presentation will explore the current advancements, challenges, and future directions of AI-assisted drug delivery, highlighting real-world applications and ongoing research efforts.

**PREBIOTIC JELLIES: An INNOVATIVE APPROACH TO FUNCTIONAL FOOD DEVELOPMENT**

T. Sravya, M sathi Paul.
Department of pharmacology, Raghu college of pharmacy, Vishakhapatnam, Andhra Pradesh , India.
thotapallisravya@gmail.com

Prebiotics are non-digestible food ingredients that selectively stimulate the growth and activity of beneficial gut microbiota, thereby contributing to improved gastrointestinal health and overall well-being. The incorporation of prebiotics into functional foods has gained increasing attention in recent years, with jelly-based formulations emerging as an innovative and consumer-friendly approach. Prebiotic jellies combine the palatability and convenience of traditional jelly products with the health-promoting properties of prebiotic fibers such as inulin, fructooligosaccharides (FOS), galactooligosaccharides (GOS), resistant starch, and pectin. These compounds not only serve as

ISBN: 978-81-980623-8-3

substrates for beneficial bacteria like Bifidbacterium and Lactobacillus but also improve jelly texture, sweetness, and stability. The preparation of prebiotic jelly involves dissolving fruit juice and sugar, followed by the addition of prebiotics, citric acid for flavor and pH adjustment, and a gelling agent such as gelatin, agar, or carrageenan. The mixture is thoroughly blended, poured into molds, and cooled to set into a functional jelly product. Such formulations are particularly valuable for children and the elderly, offering a tasty and easy-to-consume alternative to conventional prebiotic supplements. Moreover, the potential development of synbiotic jellies, combining both probiotics and prebiotics, further enhances their therapeutic relevance.

**Keywords**: Prebiotics; Functional foods; Jellies; Gut microbiota; Inulin.

**FORMULATION AND IN VIVO EVALUATION OF PARACETAMOL 1000 MG SUSTAINED RELEASE TABLETS PREPARED BY BANANA STARCH FOR DUAL-ACTION CONTROL**

Chirravuri S Phani Kumar
School of Pharmacy, Aditya University, Surampalem-533437, India.
chsphanikumar@gmail.com

This study aims to evaluate the dual functionality of banana strarch (BS) as a disintegrant in the immediate release (IR) and as polymer for controlled release (CR) in the sustained release (SR) paracetamol tablet formulation. Additionally, the study investigates the in vivo performance of the optimized formulation to ensure reliable predictive performance. The overarching goal is to develop a formulation that optimizes drug release for 12 houres, reducing dosing frequency, and minimize flushing and hepatotoxicity for better therapeutic outcomes.The IR layer was formulated using BS as a disintegrant to ensure rapid onset of action, while the CR layer employed BS as a release rate retardant for prolonged drug release. The optimized SR tablet (SR1) was developed by selecting best performing IR and CR formulations based on in vitro studies. The formulation was further evaluated in vivo using rabbits, with SR tablets adjusted to the rabbit dose (SR1-R). The optimized SR1tablet demonstrated a steady, zero-order drug release profile with enhanced pharmacokinetics. The formulation showed a high similarity between the human (SR1) and rabbit (SR1-R) equivalents, with dissimilarity (f1) and similarity factors (f2) 2.60% & 86.60%. An in vitro-in vivo correlation (R2= 0.9816) indicated reliable predictive performance, validating the effectiveness of the formulation. The SR1 tablet exhibited improved safety, efficacy, and patient compliance, making it a promising option for managing high fever conditions, including COVID-19. The combination of IR and CR layers with banana starch effectively optimizes optimizes drug release, enhance therapeutic performance, and reduces dosing frequency.

**Keywords**: Paracetamol, Immediate release layer (IR, )Controlled release layer (CR), Sustained-Release (SR), In vivo studies.

**DESIGN, OPTIMIZATION AND CHARACTERIZATION OF VITAMIN D3 LOADED PLGA NANOPARTICLES FOR INTRANASAL DELIVERY.**

Anu Hardenia, Gaurav Kant Saraogi, Ruchi Jain
Sri Aurobindo Institute of Pharmacy, Indore, Madhya Pradesh, 453555.
anuhardenia7@gmail.com

Vitamin D3 deficiency is a global health issue. Intranasal delivery offers a promising non-invasive route to improve Vitamin D3 bioavailability and patient compliance. This study aimed to develop and optimize Vitamin D3-loaded PLGA nanoparticles incorporated into a thermoreversible in-situ gel for enhanced nasal absorption and sustained release. Vitamin D3 nanoparticles were prepared using emulsification-solvent evaporation and optimized with a $3^2$ factorial design by varying PLGA and surfactant levels. Particle size, polydispersity index (PDI), and encapsulation efficiency (EE) were measured. Optimized nanoparticles were incorporated into a poloxamer-based gel. Compatibility was confirmed by FTIR and DSC, morphology by SEM, and gel properties such as gelation temperature, rheology, and mucoadhesion were assessed. In vitro release of the nanoparticle gel was compared to a conventional gel. Optimized nanoparticles showed an average size of 180 ± 7 nm, PDI of 0.16 ± 0.02, and EE of 86.2 ± 3.0%. FTIR and DSC confirmed no interaction between drug and excipients. SEM displayed spherical, smooth nanoparticles. The gel had a gelation temperature of 31 ± 1°C and mucoadhesive strength of 78 ± 6 dyne/cm². Rheological analysis showed shear-thinning behavior, ideal for nasal use. In vitro release demonstrated sustained Vitamin D3 release of 70% over 24 hours from the nanoparticle gel, versus 46% from conventional gel. The developed Vitamin D3-loaded PLGA nanoparticle gel exhibits favorable characteristics for intranasal delivery, promising improved absorption and sustained drug release.

**Keywords**: Vitamin D3, PLGA nanoparticles, Intranasal delivery, In-situ gel, Sustained release.

**DEVELOPMENT AND CHARACTERIZATION OF PROLIPOSOMES FOR SAFER ORAL DELIVERY OF DICLOFENAC (NSAIDS)**

Borade T1, 2, Pandey S.P.2, Saini T. R.2
1Indore Institute of Pharmacy, Rau, Indore, Madhya Pradesh
2Department of Pharmacy, Shri G.S Institute of Technology and Science, Indore, Madhya Pradesh, India
boradetamanna@gmail.com

Non-steroidal anti-inflammatory drugs (NSAIDs) are frequently ingested by a substantial fraction of the population for its analgesic, antipyretic, and anti-inflammatory actions and are the second leading cause of GI ulceration, affecting between 15 and 40% of people who regularly take NSAIDs. The link between NSAIDs use and the occurrence of stomach bleeding and ulceration has been established, and it has been linked to life-threatening consequences such as ulcer perforation caused by oral administration. To overcome the disadvantages of oral delivery of NSAIDs, in the present study diclofenac-loaded proliposomes were prepared and evaluated to explore the feasibility of proliposomes as a drug carrier which would generate diclofenac sodium-bearing liposomes soon after they come in contact with body fluid. The proliposomes were prepared by film deposition on carrier method by rotatory evaporator. Optimization studies were performed with the help of Design expert software using Box-Behnken model. The prepared optimized proliposomes were evaluated through vesicle size, PDI, entrapment efficiency, TEM and in-vitro drug release. The vesicle size and PDI were 162.5 nm and 0.291 respectively. The morphological evaluation was done by optical microscopy and TEM. Drug entrapment efficiency (EE%) was found to be 67.56%±0.4. An in-vitro drug release was carried out using the dialysis bag method as it has shown cumulative release of 44.64%±1.74 in 30 mins. and 98.64%±1.44 in 2 hours. This demonstrated an enhancement in the drug diffusion and thereby, absorption of the drug through the membrane. The analysis indicates that proliposomes could be utilized as drug delivery for NSAIDs.

**Keywords**: Proliposomes, Nonsteroidal anti-inflammatory drugs, oral delivery, optimization, diclofenac sodium

**ADVANCED FORMULATION DESIGNED FOR EFFECTIVE MANAGEMENT OF DYSMENORRHEA**

Suruchi Sahu, Harish Bharadwaj
Faculty of Pharmacy, Shri Rawatpura Sarkar University, Raipur, Chhattisgarh, India 493661.
suruchisahu65@gmail.com

Dysmenorrhea is characterized by painful menstrual cramps, significantly impairs the quality of life in reproductive-age women. Conventional pharmacological interventions, such as NSAIDs and hormonal therapies, provide symptomatic relief but are often limited by side effects, tolerance, and lack of patient-specific optimization. To overcome these limitations, recent research is shifting toward the development of novel formulations incorporating advanced drug delivery systems and artificial intelligence (AI)-based optimization strategies. Advances in nanotechnology and polymeric drug delivery platforms have enabled the development of stimuli-responsive systems that release drugs in response to physiological triggers, providing on-demand pain relief. These emerging formulation strategies aim to overcome the limitations of conventional therapies by offering targeted, sustained, and patient-friendly drug delivery options. Continued research and clinical evaluation of these novel systems are essential to establish their therapeutic efficacy, safety, and acceptability ultimately improving dysmenorrhea management and enhancing women's reproductive health care. Additionally, AI-driven predictive modeling, molecular docking, and machine learning algorithms are being employed to optimize excipient selection, dosage design, and

ISBN: 978-81-980623-8-3

personalized treatment protocols. This synergy between pharmaceutical innovation and computational intelligence holds the potential to revolutionize dysmenorrhea management by delivering targeted, efficient, and patient-centric therapies. Future directions emphasize integrating AI-enabled formulation design with clinical validation to develop sustainable and precision-based therapeutics for dysmenorrhea.

**THERMORESPONSIVE HYDROGEL FOR CO-DELIVERY OF NITROGLYCERIN AND AGMATINE SULFATE ENHANCES REGENERATION IN VOLUMETRIC MUSCLE LOSS**

Amol Tatode a, Milind Umekar a, Jayshree Taksande a, Tanvi Premchandani a Mohammad Qutub a
A Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, INDIA.

Volumetric muscle loss (VML) is a debilitating condition characterized by significant tissue loss and functional impairment with limited intrinsic regenerative potential. This study focuses on the development and evaluation of an injectable, thermoresponsive hydrogel for the sustained co-delivery of Nitroglycerin (NTG) and Agmatine Sulfate (AGS) to promote muscle regeneration. A hydrogel composed of Poloxamer 407 and HPMC was formulated, optimized, and extensively characterized for its physicochemical properties, including gelation kinetics, rheology, morphology, and drug release profiles. The therapeutic efficacy of the hydrogel was subsequently assessed in a rat VML model through comprehensive behavioral tests (grip strength, gait analysis), biochemical analysis of key inflammatory cytokines (IL-6, TNF-α, IL-10), and detailed histopathological examination. The optimized formulation exhibited ideal thermoresponsive behavior, with a rapid sol-to-gel transition at physiological temperature, shear-thinning properties for easy injection, and sustained co-release of both bioactive agents. In the VML model, the combination hydrogel resulted in significant improvements in functional recovery, evidenced by enhanced grip strength and normalized gait patterns. Furthermore, the dual-drug treatment effectively modulated the local inflammatory response and histopathology confirmed superior muscle regeneration, characterized by well-aligned muscle fibers and reduced fibrosis. This thermoresponsive hydrogel co-delivering NTG and AGS represents a highly promising therapeutic strategy for treating VML.

**Keywords**: Volumetric Muscle Loss, Thermoresponsive Hydrogel, Muscle Regeneration, Nitroglycerin, Agmatine Sulfate, Co-delivery

**INJECTABLE POLOXAMER-BASED THERMOGEL AS A DELIVERY PLATFORM FOR AGMATINE AND HYALURONIC ACID IN MUSCLE TISSUE ENGINEERING.**

Mohammad Qutub a, Amol Tatode a, Milind Umekar a, Jayshree Taksande a, Tanvi Premchandani
A Department of Pharmaceutics,
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur, Maharashtra, INDIA.

Volumetric muscle loss (VML) results in permanent functional deficits for which current therapeutic strategies are insufficient. We hypothesized that an injectable, thermoresponsive hydrogel enabling localized, sustained co-delivery of agmatine sulfate (AgS) and hyaluronic acid (HA) could synergistically promote robust neuromuscular regeneration. Here, a poloxamer-based thermogel was systematically optimized using a $3^2$ full factorial design. The lead formulation's efficacy was subsequently evaluated in a rat tibialis anterior VML model. The optimized hydrogel exhibited a physiologically advantageous gelation temperature (27 ± 1.03°C) and time (42 ± 1.4 s), with sustained bioactive release exceeding 28 days. In vivo, the AgS-HA combination therapy demonstrated profound synergistic effects, restoring grip strength and normalizing complex gait parameters to near-control levels ($P < 0.001$ vs. placebo). This functional recovery was corroborated by significantly reduced serum creatine kinase, a key marker of muscle damage. Histopathological analysis revealed near-complete restitution of mature, organized myofiber architecture with minimal fibrosis, contrasting with the extensive scar tissue in control groups. These findings demonstrate that a thermoresponsive hydrogel platform for sustained AgS and HA co-delivery effectively promotes comprehensive structural and functional recovery, representing a potent and clinically translatable strategy for VML.

**Keywords**: Volumetric muscle loss, Thermoresponsive hydrogel, Agmatine sulfate, Hyaluronic acid, Muscle regeneration, Functional recovery

**PC-851**

**NANOGEL REVOLUTION: LIPID-BASED CARRIERS FOR SMARTER TOPICAL DRUG DELIVERY**

Khomeshwari Dhawle 1, Kamalpuria Neha2, Nadeem Farooqui3, Nimita Manocha4
Indore Institute of pharmacy, Indore.

Conventional topical products like creams and ointments are commonly utilized but frequently hindered by low solubility, insufficient skin absorption, instability, and challenges with patient adherence. In order to tackle these challenges, lipid-based nanocarriers have attracted interest as viable options for delivering antifungal drugs such as terbinafine hydrochloride (TBH). These systems—comprising solid lipid nanoparticles (SLNs), nanostructured lipid carriers (NLCs), nanogels, and invasomes—provide benefits like increased drug loading, stability, controlled release, and better therapeutic results. Recent studies have used statistical optimization methods, such as factorial design, Box-Behnken design, and Central Composite Design (CCD), to improve TBH formulations. NLCs made from solid and liquid lipids, when incorporated into Carbopol-based gels, showed nanoscale particle sizes (about 111 nm), high entrapment efficiency (over 85%), longer drug release, and better skin permeation compared to traditional gels. Similarly, pH-sensitive nanogels made with natural polymers and acrylic acid provided prolonged release, stronger antifungal activity against Candida albicans, and improved skin retention compared to the commercial Lamisil cream. Invasomal gels made from phosphatidylcholine, ethanol, and terpenes like d-limonene and citral formed flexible vesicles with better skin absorption and natural antimicrobial and antifungal effects. Assessment studies validated positive gel properties, such as ideal pH, viscosity, spreadability, stability, and low irritation. In vitro and in vivo models consistently showed enhanced antifungal effectiveness and safety of optimized TBH-loaded nanocarrier gels over traditional topical products.In summary, lipid-based nanocarrier gels offer a viable approach for the topical administration of terbinafine, delivering patient-friendly, effective, and safer options for treating superficial fungal infections

**Keywords**: Lipid-based nanogels, nanostructured lipid carriers, solid lipid nanoparticles, invasomes, topical drug delivery, antifungal therapy, sustained release, skin permeation, biocompatibility, chronic wound healing, nanoformulations.

**HEPATOCYTE TARGETED ANTIVIRAL DELIVERY VIA L-HSA CONJUGATED PLGA NANOPARTICLES**

Dipali M. Dhoke, P. B. Khedekar
School of Pharmaceutical Sciences, JSPM University, Wagholi, Pune-412207, Maharashtra, India.
dhokedipali21@gmail.com

Poly(D,L-lactide-co-glycolide) (PLGA) nanoparticles (NPs) are widely explored for targeted delivery but lack sufficient surface functional groups for ligand attachment. This study employed the Interfacial Activity Assisted Surface Functionalization (IAASF) technique to introduce maleimide groups onto PLGA NPs, enabling conjugation with lactosaminated human serum albumin (L-HSA), a ligand recognizing the asialoglycoprotein receptor (ASGPR) abundantly expressed on hepatocytes. The antiretroviral drug Tenofovir Disoproxil Fumarate was encapsulated using a double emulsion solvent evaporation method and optimized via Central Composite Design. The optimized formulation consisted of 30% PLGA, 7% PLA-PEG-Maleimide, and 2.5% PVA. L-HSA was synthesized at a lactose-to-albumin molar ratio of 26–30, known to favor hepatocyte uptake. Conjugation was confirmed through SDS-PAGE and 1H-NMR, with disappearance of the maleimide aromatic proton peak indicating successful linkage. Particle sizes of unconjugated and L-HSA-conjugated NPs were 258.9 ± 2.1 nm and 262.4 ± 4.1 nm, respectively, with a slight zeta potential shift from −28.50 to −27.29 mV,

ISBN: 978-81-980623-8-3

supporting peptide attachment. DSC and XRD analyses revealed conversion of crystalline components to amorphous form without incompatibility. Drug release followed Korsmeyer–Peppas kinetics via anomalous diffusion. Cytotoxicity studies in HepG2 cells confirmed biocompatibility. In vivo biodistribution in mice demonstrated significantly higher hepatic accumulation of L-HSA-functionalized NPs at 4 h compared to other organs, confirming ASGPR-mediated targeting. Overall, L-HSA conjugation enhanced liver specificity without altering nanoparticle integrity, demonstrating its potential for targeted antiviral therapy.

**ASSESSMENT AND EVALUATION OF PRESCRIBING PATTERN OF ANTIMICROBIAL AGENTS IN INTENSIVE CARE UNIT OF TERTIARY CARE HOSPITAL**

Keyaa Savalia, Vishwa Patel, Tarachand Lalwani, Shrikalp Deshpande
Department of Pharmacy Practice, KB Institute of Pharmaceutical Education and Research, Gandhinagar, Gujarat, India - 382023
keyaas02@gmail.com

The evaluation of antimicrobial prescribing patterns and microbial sensitivity in Intensive Care Units (ICUs) is critical for optimizing infection control and combating antimicrobial resistance. Inappropriate use facilitates resistance and cross-transmission, particularly during inter-ward transfers. This prospective observational study, conducted over six months in a tertiary care hospital, investigated antimicrobial utilization and sensitivity trends among critically ill patients. A total of 250 ICU patients receiving antimicrobials were enrolled (58% male, 42% female), with the highest representation in the 61–70 year age group (27.6%). Patients were admitted across multiple ICU types, predominantly the General ICU (36%) and Medical ICU (30%). Overall, 644 antimicrobial agents were prescribed, with cephalosporins, carbapenems, antiprotozoals, and azole derivatives being most common. Cefoperazone-sulbactam was the predominant cephalosporin, while meropenem was the leading carbapenem. Culture investigations were performed in 191 patients (76%), yielding positive results in 62.3%. Respiratory samples were the most frequent (31.56%). Gram-negative organisms accounted for 85.34% of isolates, with gram-positive bacteria representing 14.66%. Gram-negative isolates demonstrated high sensitivity to colistin and tigecycline, whereas amphotericin B, caspofungin, and flucytosine exhibited complete efficacy against Candida species. Resistance was most prominent with second-generation cephalosporins and penicillins. The findings indicate that antimicrobial prescribing was largely rational; however, variable resistance patterns emphasize the need for robust antimicrobial stewardship.

**Keywords**: Antimicrobial agents, prescription pattern, sensitivity, ICU.

**PC-854**

**DESIGN AND CHARACTERIZATION OF PHYTOHORMONE ORAL DISSOLVABLE FILMS AS A NOVEL DRUG DELIVERY SYSTEM FOR WOMEN'S HEALTH**

R.pratheesha , S. Swetha, T. Shri Vijaya Kirubha
Department of Pharmacognosy,
Mother Terasa College of Pharmacy, Illuppur, Pudukkottai 622 102, Tamil Nadu.
pratheesharavichadran@gmail.com

Hormonal imbalances in women, particularly during premenstrual, perimenopausal, and postmenopausal stages, are associated with physiological and psychological challenges including menstrual irregularities, hot flashes, osteoporosis, and mood disturbances. Conventional hormone replacement therapy (HRT), though effective, carries long-term risks such as cardiovascular complications and hormone-sensitive cancers. Hence, there is growing interest in phytohormones-plant-derived compounds with estrogenic, progestogenic, and adaptogenic properties-as safer alternatives.The present work aims to develop and evaluate a novel oral dissolvable film (ODF) incorporating standardized extracts of soy isoflavones, red clover, flaxseed lignans, and Shatavari as a phytohormone supplement for women's health. The ODF was prepared using the solvent casting method with hydroxypropyl methylcellulose (HPMC E15) as the polymer and glycerol as the plasticizer. The films demonstrated uniform thickness (0.182 ± 0.015 mm), rapid disintegration (28.4 ± 3.1 seconds), and acceptable folding endurance (>250 folds). Drug content uniformity was maintained at 96.8 ± 2.1%, while in vitro release studies showed 84.7 ± 3.4% phytohormone release within 20 minutes. Sensory evaluation confirmed good palatability and patient acceptability.The results indicate that oral dissolvable films loaded with phytohormones represent a novel, patient-compliant dosage form, particularly advantageous for women with swallowing difficulties and those seeking a natural, side-effect-minimized alternative to HRT. This innovative delivery system holds potential for improved bioavailability, enhanced compliance, and holistic management of menopausal and menstrual health.

**Keywords**: Phytohormones, Phytoestrogens, Oral dissolvable films (ODFs), women's health

**FORMULATION AND EVALUATION OF FENUGREEK TABLETS**

[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4].
[1234]Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai, Tamilnadu.
indiakbv@gmail.com

Fenugreek (Trigonella foenum-graecum) is a well-recognized medicinal plant valued for its hypoglycemic, hypolipidemic, antioxidant, and anti-inflammatory activities. Its seeds contain a diverse phytochemical profile—saponins, alkaloids (notably trigonelline), flavonoids, mucilage, and dietary fiber—making them a promising candidate for herbal dosage forms. In the present work, fenugreek seed powder was carefully cleaned, dried, milled, and sieved to achieve uniform particle size. Tablets were then prepared using the direct compression method with suitable pharmaceutical excipients such as fillers, binders, lubricants, and disintegrants. Pre-compression parameters, including angle of repose, bulk density, tapped density, and Carr's index, were evaluated to ensure acceptable flow properties. Post-compression studies—weight variation, hardness, friability, thickness, disintegration time, and in vitro dissolution—were carried out in accordance with pharmacopeial standards. The optimized tablets displayed uniformity of weight, adequate hardness, low friability, and acceptable disintegration time. Dissolution studies indicated a satisfactory release of active constituents, confirming the feasibility of fenugreek in a solid oral dosage form. Beyond therapeutic activity, the tablet format offers additional benefits such as improved stability, accurate dosing, ease of administration, and better patient compliance.

**Keywords**: Fenugreek tablet, Direct compression, Disintegration , dissolution, Hypoglycemic herbal formulation.

**PC-856**

**DESIGN AND CHARACTERIZATION OF CURCUMIN-LOADED MSN@GO FOR WOUND MANAGEMENT**

P N Ingale, B. R. Dravyakar
SVKM's Institute of Pharmacy, Dhule, Maharashtra

Curcumin (CU) is a polyphenolic natural compound having beneficial effect in the management of wound used from historic times in India. In the contemporary investigation, an attempt has made to fabricate novel mesoporous graphene oxide nanocomposite comprised of curcumin for management of wound healing. The one-pot oil-in-water, biphasic stratification method used to synthesize mesoporous silica graphene oxide nanocomposite (GO@MSN). Passive loading approach used for fabrication of CU-GO@MSN nanocomposite. The preliminary characterization of GO, CU and CU-GO@MSN was done using UV-visible spectroscopy and Fourier Transform Infra-Red Spectroscopy. The In-vitro HET-CAM assay proved the wound healing potential of prepared composite with comparative high antimicrobial efficiency against Escherichia Coli and Staphylococcus Aureus. The BET analysis reveals that the mesoporous structure formed successfully and having larger surface area and pore volume. For enhancing the effectiveness and delivery, nanocomposite dispersed into film forming gel. The film characterized for texture, thickness, folding endurance, percent moisture and solubility.

**DEVELOPMENT AND EVALUATION OF HERBAL FOOT SPRAY FOR ODOR CONTROL AND ANTIMICROBIAL ACTIVITY**

Nikita Navsare [1], Vaishali Pardesi [1]
[1]Department of Pharmaceutical Quality Assurance, Alard School of Pharmacy, Pune – 411057, India

An antibacterial foot spray is a convenient and effective solution designed to promote foot hygiene, combat odours, and prevent bacterial and fungal infections. One part of the body that is very important for humans is the feet, both for women and for men, therefore feet need to be kept clean but sometimes they are often ignored, resulting in the appearance of odour problems on the feet. Foot odour is caused by the metabolic activities of normal bacterial inhabitants of feet. The main objective of using foot spray is to mask odour and inhibit bacterial growth. Foot spray also helps in prevention of infection. The different herbal powder used are exacted using Soxhlet apparatus using ethanol as solvent. The ethanol is used because it more effective in extraction of Eugenol as it acts as antibacterial component. On the basis of comparative study and evaluation it was found that F3 was more effective than F1 and F2 as the concentration of Betel Leaf extract was more. The pH of F3 was more equivalent to the pH of skin.

**Keywords**: Antimicrobial, Herbal, Beetal leaf, Soxhlet extraction, Foot care

**BANANA POWDER: A POTENTIAL SUPER-DISINTEGRATING AGENT IN FAST DISSOLVING TABLET**

Chaitrali Bidikar1, Juvatkar PV1, Sunaina Ghodse1, Ashwini Bharati1, Aditi Mhatre1, Vanita Kanase1
1. AIMS College of Pharmacy, AIMS Foundation, Vadavali, Dombivali (E)

The purpose of this research was to introduce and evaluate natural excipient that has versatile property in the oral disintegrant and immediate release formulations. This natural excipient was used as disintegrant in the formulation of orodispersible tablets of some model drugs such as lisinopril. Orodispersible tablets are useful in patients, such as pediatric, geriatric, bedridden or developmentally disabled, who may face difficulty in swallowing conventional tablets or capsules and liquids orals or syrup, leading to ineffective therapy, with persistent nausea, sudden episodes of allergic attack or coughing for those who have an active life style. Fast onset of action-dispersible tablet has major advantage that the drug product is already in solution at that time it is consumed. Thus, the absorption will be faster and more complete than with conventional tablet. Lisinopril is a lysine analog of enalapril at, the active metabolite of enalapril. It is a long-acting, non-sulfhydryl angiotensin-converting enzyme (ACE) inhibitor that is used for the treatment of hypertension and congestive heart failure in daily dosages of 10-80 mg. The aim of this study is to formulate various batches of oral disintegrating tablets of lisinopril by using Banana powder with different concentrations 5%, 10%, 15%, individually by using different diluents like Mannitol and Lactose by wet granulation method. The tablets will be evaluated for the precompression parameters such as bulk density, compressibility, angle of repose etc. and post compression parameters like hardness, weight variation, friability, disintegration time and in-vitro dissolution profiles. Tablets containing banana powder as disintegrating agent will disperse rapidly and can be an alternative for present disintegrating agent and will be more economical.

**Keywords**: Orodispersible tablets, disintegration time, banana powder, Super disintegrant.

**DESIGN AND OPTIMIZATION OF LIQUISOLID COMPACTS FOR IMPROVED SOLUBILITY OF BCS CLASS II DRUGS**

Rekha Salve, Jayendrasing Bayas
School of Pharmaceutical Sciences, JSPM University, Wagholi, Pune, Maharashtra, India - 412207.
rvs.ccopr@gmail.com

The objective of this research was to formulate liquisolid compacts of Azilsartan Medoxomil that improve the solubility. Azilsartan Medoxomil, is a potent angiotensin II receptor blocker, is use for the management of hypertension. Thes compact were prepared by varying ratio of PEG 400, avicel pH 102 and aerosil as vehicle, carrier, and coating material respectively, these batches further formulated as tablet by direct compression method. Different formulations were prepared produced high dissolution profile and they showed significant higher drug release rates than conventional tablets due to increase in wetting properties and surface of drug available for dissolution. The prepared batches of tablets were evaluated by using FTIR, DSC, studies revealed that there was no chemical interaction between the drug and the excipients, hardness 4-5 kg/cm2, thickness 1-2 mm, friability 0.1-0.5 %, weight variation 100 mg, drug content was 99.1-102 %, in vitro disintegration time 5-6 min. And in vitro dissolution studies showed enhance drug solubility as compared to marketed formulation. The results of stability studies indicated no significant changes with respect to physicochemical properties, in vitro disintegration time, and in vitro drug release. This formulation represents valuable strategy in overcoming dissolution challenges, ultimately contributing to the development of effective and patient-friendly drug delivery system.

**Keywords**: liquisolid compacts, Azilsartan Medoxomil, solubility, dissolution rate.

**DEVELOPMENT AND CHARACTERIZATION OF A NOVEL MUCOADHESIVE FILM FOR THE LOCALIZED MANAGEMENT OF PERIODONTITIS USING HERBAL ESSENTIAL OIL**

Mahhak Khan
Department of Pharmaceutics, HK College of Pharmacy, Mumbai, Maharashtra, India-400102
mahhakkhan184@gmail.com

A novel mucoadhesive film was developed for the localized management of periodontitis, a chronic inflammatory disease initiated by a polymicrobial biofilm. The film was fabricated by the solvent casting method and incorporated a synergistic blend of herbal essential oils with proven antibacterial and anti-inflammatory potential. The formulation was optimized for mechanical strength, folding endurance, thickness uniformity, and surface pH, ensuring safety and comfort during insertion into periodontal pockets (~5 mm), the primary site of disease pathology. Texture analysis confirmed the presence of strong mucoadhesive properties, enabling reliable retention at the site of application. In vitro release studies demonstrated a controlled, prolonged release profile of the active constituents. Antimicrobial testing, conducted through MIC and MBC assays, showed significant inhibition of major periodontal pathogens, with superior efficacy compared to a marketed reference product. An integrated handle strip was incorporated into the film design, enabling precise and convenient self-placement by the patient, thus enhancing compliance and localized delivery. Stability studies further confirmed the physical and chemical integrity of the formulation. This innovative mucoadhesive film provides sustained antimicrobial action directly within periodontal pockets, thereby extending residence time and reducing the need for frequent dosing. By combining herbal essential oils, the system holds strong potential as an adjunctive therapy to mechanical plaque removal, addressing the underlying microbial and inflammatory pathology and improving patient outcomes in periodontitis management.

**Keywords**: Periodontitis, Mucoadhesive film, Herbal actives, Essential oils, MIC, MBC, Local drug delivery, Antimicrobial efficacy, Sustained release.

**SMART FILM-FORMING SPRAY OF MICONAZOLE NITRATE: A NOVEL APPROACH FOR TOPICAL FUNGAL INFECTIONS**

Anbarasu Murugan[1], Kamal Karunanithi[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4].
[1234]Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai, Tamilnadu.
indiakbv@gmail.com

The study aimed to formulate, optimize, and characterize a novel Miconazole nitrate film-forming spray for the effective treatment of topical fungal infections. The main objective was to develop a 1% Miconazole nitrate spray formulation with enhanced skin permeation, sustained drug release, and improved patient compliance using Central Composite Design (CCD).The film-forming spray was prepared by the solvent evaporation technique. Central Composite Design with three independent variables (Eudragit RSPO, Ethyl cellulose, and camphor–menthol eutectic mixture) and two dependent responses (viscosity and drug permeation) was employed for optimization. Formulations were

ISBN: 978-81-980623-8-3

evaluated for pH, viscosity, spray angle, spray pattern, evaporation time, in-vitro permeation, and antifungal activity. Stability studies were conducted at 25±2°C and 60±5% RH for two months. The optimized formulation containing 5% Eudragit RSPO, 2.5% Ethyl cellulose, and 12.5% camphor–menthol eutectic mixture exhibited desirable physicochemical and functional characteristics. The viscosity was ~12 cps, spray angle ~58°, pH 5.1, and in-vitro drug permeation reached ~95% within 7 hours. The formulation showed strong antifungal activity against dermatophytes and yeasts, with improved stability and no significant changes in appearance or pH during storage. The developed Miconazole nitrate film-forming spray is stable, effective, and superior to conventional topical dosage forms. It represents a patient-friendly, innovative drug delivery system for treating fungal infections.

**Keywords**: Miconazole nitrate, Antifungal, Film-forming spray, Optimisation.

**TOPICAL DELIVERY ENHANCEMENT OF LULICONAZOLE VIA LIPOSOMAL GEL: DESIGN, CHARACTERIZATION AND FOR SKIN FUNGAL INFECTION**

Divya Shree V, Padmasree M, Vishwanath B A
Department of Pharmaceutics, Aditya Bangalore Institute of Pharmacy Education and Research, Yelahanka, Bangalore, Karnataka, India-560064
divyashree.lokesh54@gmail.com

The study focuses on the formulation and optimization of a Luliconazole-loaded liposomal gel to overcome limitations of conventional topical therapy and achieve improved retention, penetration, and sustained antifungal activity. Pre-formulation studies, including solubility, FTIR, and UV analysis, confirmed drug–excipient compatibility. Liposomes were prepared by the thin-film hydration method and incorporated into a 1% Carbopol 934 gel. Nine formulations (F1–F9) were systematically optimized by varying lipid ratios, cholesterol content, and hydration time to obtain desirable particle size, entrapment efficiency, and stability.Comparative studies with a marketed Luliconazole gel confirmed that both formulations exhibited comparable drug content, validating the accuracy and efficiency of drug loading into the liposomal system. In-vitro release studies using Franz diffusion cells revealed a distinct difference in release profiles between the two formulations. The marketed gel displayed a rapid drug release pattern, whereas the liposomal gel demonstrated a slower, sustained release over an extended period. This sustained release behavior of the liposomal gel suggests a prolonged therapeutic effect, which may reduce dosing frequency and improve patient compliance. The optimized liposomal gel showed a drug content of 98.8%, In-vitro drug release of 92% and follows zero order, first order, Higuchi plot & Kors-peppas. The present research work emphasize the potential of Luliconazole liposomal gel as an effective topical delivery system for enhanced management of dermal fungal infections.

**Keywords**: Luliconazole, Liposomal gel, Topical antifungal, Thin film hydration method

**FORMULATION AND EVALUATION OF VITAMIN D3 CHEWABLE TABLET AS ANTIHYPERTENSIVE AGENT**

Kalane Dnyaneshwari Suresh, Khedkar Amol Navnath
Student, Shantiniketan College of Pharmacy, Dhotre BK 414304
dkalane2003@Gmail.com

The purpose of this study was to use excipients in a wet granulation process to create vitamin D3 chewable tablets for Hypertension. A range of tests, including weight variation, thickness, hardness, and disintegration, were performed on the tablets, and the results met pharmacopeial specifications. Every physical property that was examined indicated that every excipient was appropriate for use in tablets. Since a chemical is broken down into particles in the oral cavity to make swallowing easier, water is not required for administration. This effort aimed to reduce formulation complexity, create a cost-effective solution, and deliver vitamin D3 in granular and tablet form with enhanced dispensability.

**Keywords**: Vitamin D3, Gingerol, wet granulation, Chewable Tablet, antihypertension.

**PC-864**

**FORMULATION AND EVALUATION OF ALVERINE CITRATE-LOADED POLYMERIC NANOPARTICLES FOR ORAL DELIVERY**

Avhad Varsharani, Randhawan Bhagyashri
Department of Pharmaceutical Sciences, Arihant College of Pharmacy, Kedgaon, Ahilyanagar, Maharashtra, India - 414005.
varsharkarad30@gmail.com
bhagyashrirandhawan@gmail.com

The present study aimed to formulate and evaluate polymeric nanoparticles of Alverine Citrate for oral administration. Alverine Citrate was selected as a suitable drug for polymeric nanoparticles due to its low solubility, low bioavailability, and high frequency of administration. The nano-precipitation method was used to prepare nanoparticles so as to avoid both chlorinated solvents and surfactants to prevent their toxic effect on the body. Polymeric nanoparticles of Alverine Citrate were prepared by using hydrophilic polymers such as chitosan and HPMC K100M. The prepared formulations were then characterized for particle size, polydispersity index, zeta potential, loading efficiency, encapsulation efficiency, and drug-excipient compatibility. The average particle size is 114.8 nm, PDI of 0.366, zeta potential is in the range of -2.4 mV, drug content is in the range of 96.87%, entrapment efficiency of 85.78%, and loading efficiency is in the range of 40.15%. Transmission Electron Microscopy (TEM) analysis of the polymeric nanoparticles showed the spherical shape of the nanoparticles. The Differential Scanning Calorimetry (DSC) study confirmed that there was no intermolecular interaction between the drug and polymer. FTIR study concluded that no major interaction occurred between the drug and polymers used in the present study.

**Keywords**: Alverine Citrate, Chitosan, Nano precipitation, Entrapment efficiency.

**PC-865**

**INNOVATIVE ORAL DOSAGE FORM: DICLOFENAC SODIUM INCORPORATED MEDICATED CHOCOLATES**

Sanapala Usharani, R. Sailaja
Department of Pharmaceutics, Raghu College of Pharmacy, Dakamarri, Visakhapatnam, Andhra Pradesh, India.

Patient compliance remains a major challenge in oral drug delivery, particularly among paediatric and geriatric groups. The present study aims to formulate and evaluate medicated chocolates of Diclofenac using synthetic and natural excipients. Diclofenac is a phenyl acetic acid derivative and a non-steroidal anti-inflammatory drug, shown to act by inhibiting prostaglandin synthesis by inhibiting cyclooxygenase-1 and cyclooxygenase-2. Diclofenac belongs to the BCS class II and has poor solubility and a bitter taste. The main aim of the present research work is to formulate medicated chocolates containing Diclofenac sodium, a widely prescribed NSAID, through the incorporation of solid dispersions prepared by the solvent evaporation method. Solid dispersions of Diclofenac sodium were prepared using hydrophilic carriers such as Polyethylene glycol (PEG 4000/6000), Eudragit, and Carbopol to improve solubility and dissolution. The drug-carrier mixtures were dissolved in suitable solvents, evaporated under controlled conditions, and the dried solid dispersions were incorporated into Cocoa butter, cocoa powder, and also using natural excipients. The chocolate was evaluated for various parameters, including hardness, appearance, thickness, weight variation, assay, disintegration, dissolution, blooming, stability test, drug content uniformity, and melting point. Medicated chocolates formulated with Diclofenac sodium solid dispersions by moulding technique present a novel, palatable, and patient-friendly delivery system with improved solubility, dissolution rate, and potential bioavailability, and also achieved taste masking.

**Keywords**: Diclofenac sodium, Medicated Chocolates, Solvent evaporation, Solid dispersions.

ISBN: 978-81-980623-8-3

Garlic peel which is a significant agro industrial waste, is a valuable source of nutrient version into powder used to enrich food and is ash content, which provide insights into its mineral profile. Research shows garlic peel powder is rich in crude fibre, carbohydrates, proteins and significant such of total phenolic and flavonoid compounds which provide strong anti-oxidant activity which can combat few radicals and reduce oxidative stress. Garlic peel powder have health promoting compounds phenyl propanoids like N-Trans- coumaroyl octopamine and N-Transferuloyl octopamine, as well as phenolic acid like caffeic acid and ferric acids. These compounds showed anti-inflammatory, anti-microbial and potential anti-cancer. Ash content refers to inorganic mineral matter that remains after organic material has been burned and ash content provides metric for its total mineral composition (16.35%) high content of minerals. Ongoing research to develop function foods and exploring application in medicine and sustainable agriculture.

**Keywords**: Hair loss, Hair strengthening, Anti-inflammatory, Anti-microbial.

**PC-867**

## SOLUBILITY ENHANCEMENT OF POORLY SOLUBLE DRUG BY CO CRYSTALLIZATION AND FORMULATE INTO FILMS

J. Meghana, A. Lakshmi usha

Poor aqueous solubility remains a major challenge in the development of oral dosage forms, particularly for Biopharmaceutics Classification System (BCS) class II drugs, where dissolution is the rate-limiting step for absorption. Itraconazole, an antifungal agent with low solubility and high permeability, was selected for this study. The aim was to enhance its solubility and therapeutic efficacy through co-crystallization and subsequent formulation into mucoadhesive buccal films. Co-crystals of itraconazole were prepared using benzoic acid and salicylic acid as co-formers via the solvent evaporation method. These co-crystals were incorporated into films using hydroxypropyl methylcellulose (HPMC K15M) as a polymer through the solvent casting technique. The prepared films were evaluated for physical parameters, drug content, and in-vitro drug release. Among the formulations, those containing benzoic acid co-crystals exhibited superior solubility enhancement and improved drug release compared to pure itraconazole.From the above formulations F1 shows 96% drug release.The study concludes that co-crystallization coupled with buccal film formulation is an effective strategy to enhance solubility, dissolution, and potential bioavailability of poorly soluble drugs like itraconazole, thereby improving their therapeutic performance.

**PC-868**

## NANOTOXICOLOGY: ENSURING THE SAFE TRANSLATION OF NANOMEDICINE FROM BENCH TO BEDSIDE

Bhoomika, Vineela haasiny
Department of Pharmacy Practice, Annamacharya college of pharmacy(autonomous), Rajampeta, Andrapradesh, India-516115.
bhoomikabhoomi5757@gmail.com

Nanomedicine has significantly changed diagnosis and therapeutics with the development of new drug delivery, controlled release and sustained release systems as well as modified pharmacokinetics using nanoscale materials. Yet, these intriguing features as a result of their reduced size, large surface-to- volume ratio and capability to cross biological barriers have latterly cast apprehensions for their toxic potential leading to an entirely new scientific field called "nanotoxicology". Nanotoxicology is intended to systematically analyze the interactions of nanomaterials with biological systems in health and disease, highlighting parameters including particle size, shape, surface charge, chemical composition as well as dose-dependent effects controlling biodistribution diagnostic use, accumulation and clearance from organism and immune system reactions. Primary modes of toxicity are thought to involve oxidative stress, genotoxicity, inflammation and protein corona formation that changes biological identity and cell uptake. Current evaluation methods include in vitro cytotoxicity and genotoxicity testing, in vivo biodistribution and organ toxicity research, and safety potential in modeling. There remain, however, gaps in both knowledge and methods that make this application challenging: there is no standard protocol for testing; very limited long-term exposure data exists and the rigorousness of correlating animal studies or in vitro results with human impacts is daunting. To minimize the risks safety-by-design paradigm, biocompatible coatings, bio degradable nanomaterials and AI-driven predictive models are advocated. To ensure the safe transition of nanomedicine from bench to bedside with minimum environmental and occupational risk, it will be essential for there to be an increased focus on regulatory development, harmonization of international guidance and academia- industry public health liaison.

**Keywords**: Nanotoxicology, Nanomedicine, Safety-by-Design, Biodistribution, Risk Assessment.

## DESIGN AND EVALUATION OF A MULTI-UNIT PARTICULATE SYSTEM FOR CONTROLLED DELIVERY OF ANTIDIABETIC AND ANTIHYPERTENSIVE DRUGS USING EXTRUSION–SPHERONIZATION.

Vipul Arun Mujage, K. R. Jadhav, Dhanashree P. Sanap.
Bharati Vidyapeeth's College of Pharmacy, Sector 8, C.B.D Belapur, Navi Mumbai- 400614.

The present study focuses on the formulation and evaluation of a Multi-Unit Particulate System (MUPS) containing anti-diabetic and anti-hypertensive drugs, specifically gliclazide, sitagliptin, and diltiazem. Oral solid dosage forms, particularly MUPS, offer significant advantages over conventional systems by enhancing drug stability, bioavailability, and patient compliance while minimizing dose dumping and variability in absorption. MUPS comprises multiple pellets that allow for controlled and immediate drug release patterns, thereby optimizing therapeutic outcomes for chronic conditions such as diabetes mellitus and hypertension. The research explores extrusion-spheronization as an effective technique for pellet preparation, ensuring uniformity, sustained release, and improved pharmacokinetic profiles. Additionally, fixed-dose combinations (FDCs) are employed to reduce medication burden, enhance adherence, and lower healthcare costs. This study highlights the potential of MUPS in overcoming challenges associated with multi-drug regimens and provides a promising approach for better management of coexisting diabetes and hypertension.

**Keywords**: Multi-Unit Particulate System, Fixed-Dose Combination, Gliclazide, Sitagliptin, Diltiazem, Extrusion-Spheronization, Diabetes Mellitus, Hypertension.

## TO PREPARE AND EVALUATE A HYDROGEL CONTAINING DICLOFENAC SODIUM USING BIONANOCOMPOSITE

B. Arthi Saranya, A. Lakshmi Usha

Topical drug delivery involves applying medications directly to the skin or mucous membranes to treat localized conditions or achieve systemic absorption . Nonsteroidal anti-inflammatory drugs (NSAIDs) are a FDA-approved agents widely used for their antipyretic, anti-inflammatory, and analgesic properties. Diclofenac sodium was selected as the drug of choice for this study. Hydrogels were prepared using physical and chemical cross-linking methods, employing natural polymers such as Gond Kataria and Acacia arabica. Different concentrations (0.3g,0.4g, and 0.5 g) of Gond Kataria and Acacia arabica, individually and in combination, were dispersed in distilled water and allowed to swell in the dark for 24hours. The swollen dispersions were mixed under magnetic stirring (500rpm), followed by the addition of 0.1ml isopropyl alcohol and Tween 80, and the final volume was adjusted with distilled water to obtain a homogeneous gel. The formulations were evaluated for drug content, pH determination, and viscosity. The results indicated that the solubility of diclofenac sodium was enhanced by the bionanocomposite technique .Among all formulations ,F2 showed optimal performance ,with 99%drug release over 8hours and superior overall characteristics . FTIR analysis confirmed no significant interaction between the drug and the polymers.

## ANTIOXIDANT LOADED IN-SITU GEL FOR THE TREATMENT OF DRY EYE SYNDROME IN SJOGRENE'S DISEASE.

Shantaram Khanage, Pradnya Shinde
Department of Pharmaceutics, Loknete Appasaheb Rajale college of Pharmacy, Adinathnagar, Pathardi, Ahilyanagar, Maharashtra, India

Sjogren's disease is an autoimmune disorder characterized by chronic inflammation of the lacrimal and salivary glands, leading to aqueous-deficient dry eye syndrome. Oxidative stress contribute to ocular surface

ISBN: 978-81-980623-8-3

damage and tear film instability. This study aimed to develop and evaluate a zeaxanthin-loaded in situ gel for sustained ocular delivery and enhanced management of dry eye in Sjögren's disease. A thermo sensitive in situ gel was prepared using poloxamer 407 combined with mucoadhesive polymers to enhance precorneal residence. Zeaxanthin was incorporated as the therapeutic antioxidant. The formulation was assessed for clarity, pH, viscosity, gelation temperature, and drug content. Antioxidant activity was confirmed by DPPH radical scavenging and lipid peroxidation inhibition assays. In vitro release and ex vivo corneal permeation studies were performed. In vivo efficacy was evaluated in an experimental dry eye model mimicking Sjögren's disease through tear film break-up time (TBUT) and oxidative stress biomarkers. The optimized antioxidant loaded gel showed rapid sol-to-gel transition at physiological temperature (34–36 °C), suitable viscosity for ocular retention, and sustained drug release over 24 h. In vivo studies demonstrated significant improvements in tear secretion and TBUT, reduced corneal staining. The formulation was well tolerated with no ocular irritation. Zeaxanthin-loaded in situ gel presents a novel and innovative strategy for treating Sjögren's-related dry eye. By combining potent antioxidant activity with prolonged ocular residence, it offers potential advantages in efficacy, safety, and patient compliance.

## DEVELOPMENT OF GASTRO-RETENTIVE RAFT FORMING SYSTEM OF METFORMIN HYDROCHLORIDE

Mahendra Patel, Anjali Solanki
Department of Pharmaceutics, Sri Aurobindo Institute of Pharmacy, Indore, Madhya Pradesh, India 453555.
mahendra.patel@saip.ac.in

The present study focuses on the development of a gastro-retentive raft-forming system for Metformin Hydrochloride (MH) with the aim of enhancing therapeutic efficacy, improving oral bioavailability, and minimizing patient concerns associated with its rapid release. MH has limited absorption due to its narrow absorption window in the upper gastrointestinal tract and short gastric residence time. To overcome these limitations, a floating drug delivery system was designed using the raft-forming approach. Drug–polymer compatibility was assessed through physical observation and FTIR analysis, which confirmed no significant interactions between MH and the selected polymers. The calibration curve exhibited linearity at 232 nm, ensuring accurate analytical evaluation. Nine formulations were prepared by varying the ratios of sodium alginate, carbopol, and guar gum. Sodium bicarbonate was used as a gas-generating agent to impart buoyancy, while microcrystalline cellulose acted as a binder, talc as a diluent, and magnesium stearate as a lubricant. The prepared tablets were evaluated for weight variation, hardness, thickness, friability, drug content uniformity, buoyancy, and in-vitro drug release. All parameters were within pharmacopeial limits. Among the nine formulations, F2 showed the most promising results, releasing 99.48% of the drug within 12 hours with excellent floating ability and sustained release. In conclusion, the raft-forming gastro-retentive system proved effective in prolonging gastric retention, controlling drug release, and offering potential for improved patient compliance in diabetes management.

**Keywords**: Metformin Hydrochloride, Gastro-retentive drug delivery, Raft-forming system, Sustained release, Bioavailability

## FORMULATION AND CHARACTERIZATION OF THERMO-RESPONSIVE IN SITU GEL SYSTEM LOADED WITH TRANSFEROSOMES FOR NOSE TO BRAIN DELIVERY OF SILYMARIN

Ashly Merin George, Raja. N ,Abdul Rahman. M, Blessy. M. R.
Department of Pharmaceutics, Crescent School of Pharmacy, B.S. Abdur Rahman Crescent Institute of Science and Technology, Chennai, Tamil Nadu, India-600048
ashlymerin@gmail.com

Neurodegenerative diseases like Alzheimer's and Parkinson's affect millions globally and are characterized by the gradual loss of brain cells. Treating these conditions is difficult because many drugs can't effectively reach the brain due to natural barriers like the blood-brain barrier. This study developed a silymarin-loaded transferosomal in situ gel to enhance the nose-to-brain delivery of the poorly bioavailable neuroprotective drug. Optimized transferosomes (STs), prepared using a thin-film hydration technique, were characterized for key physicochemical properties. The vesicles demonstrated a nanoscale size range of 144.3–173.8 nm, polydispersity index (PDI) values from 0.532 to 0.628 and a zeta potential between -18.53 and -22.79 mV, indicating good colloidal stability imparted by an anionic surfactant. Entrapment efficiency was high, ranging from 76.54% to 90.15%, with formulation F4 showing the highest value. TEM analysis visually confirmed the formation of spherical, multi-lamellar vesicles. These STs were incorporated into a thermosensitive in situ gel composed of Poloxamer 127 and gellan gum, which exhibited a suitable gelation temperature (29.4–34.2°C) and pH for nasal administration, transitioning to a gel at body temperature to prolong nasal residence. In vitro drug release studies revealed a sustained release profile over 180 minutes, with the release rate modulated by the gelling agent ratio; F1 showed the most rapid and complete release (98.5%). FTIR and EDS analyses confirmed the compatibility of components and successful vesicle formation. Crucially, the optimized formulations maintained their particle size, entrapment efficiency and drug release characteristics over a three-month stability period, confirming the system as a stable and promising platform for effective nose-to-brain delivery.

**Keywords**: Neurodegenerative diseases, Alzheimer's, Parkinson's, Transferosomes, silymarin.

## PROPOLIS-BASED NANOCOMPOSITE FOR NOSE-TO-BRAIN DELIVERY

Janhavi Borkar, Dhrubojyoti Mukherjee
Department of Pharmaceutics, School of Pharmacy and Technology Management, Mukesh Patel Technology Park, SVKM's NMIMS, Shirpur Campus 425405, India
janhaviborkaro4@gmail.com

The research addresses the challenge of delivering drugs effectively to the brain, which is hindered by the blood-brain barrier (BBB) that restricts many therapeutic agents from reaching the central nervous system (CNS). Traditional drug delivery methods face limitations such as low bioavailability and non-specific distribution, causing side effects. The study proposes using intranasal (nose-to-brain) delivery as a promising alternative, leveraging the nasal mucosa's direct neural pathways (olfactory and trigeminal nerves) to bypass the BBB and achieve rapid, targeted brain drug delivery with minimized systemic side effects. Nanocomposites are explored as advanced drug carriers that enhance drug stability, solubility, controlled release, and targeting capabilities. Functionalized nanocomposites with mucoadhesive properties improve drug retention and permeation through the nasal mucosa, potentially increasing therapeutic efficacy for CNS diseases. Propolis, a natural resin with neuroprotective and pharmacological properties, is incorporated into the nanocomposite formulation to exploit its therapeutic potential against neurological disorders such as Parkinson's, epilepsy, and Alzheimer's diseases. The research involves designing a polymer hybrid nanocomposite composed of propolis, polyethylene glycol (PEG), and polyacrylamide (PAM) for intranasal administration. The formulation undergoes extensive physicochemical characterization, including particle size, zeta potential, gel fraction, swelling behaviour, porosity, and surface morphology via scanning electron microscopy (SEM). The study also includes biodistribution and biological efficacy evaluations to confirm the nanocomposite's ability to cross the BBB and deliver therapeutic agents effectively to the brain.

**Keywords**: Intranasal drug delivery, Blood-brain barrier, Nanocomposite, Propolis, CNS disorders

Fosfestrol, a nonsteroidal estrogen used in prostate cancer treatment, requires precise and reliable analytical methods for quantification in pharmaceutical formulations. This study aimed to develop and validate

ISBN: 978-81-980623-8-3

a rapid, precise, and stability-indicating Reverse Phase High-Performance Liquid Chromatography (RP-HPLC) method for the estimation of Fosfestrol in bulk and marketed dosage forms. The method was optimized using a Hypersil BDS C18 column (250 mm × 4.6 mm, 5 µm) with an isocratic mobile phase of $KH_2PO_4$: ACN: TBAH (70:30:1) at a 1.5 mL/min flow rate and detection at 240 nm. The developed method exhibited a sharp and well-resolved peak at a retention time of 12.922 min. The validation, conducted as per ICH Q2 (R1) guidelines, confirmed specificity, system suitability, precision, accuracy, linearity, robustness, and forced degradation studies. The method demonstrated excellent linearity (30–90 µg/mL, $r^2$ = 0.998), high accuracy (98–102%), and precision (%RSD < 2). Forced degradation studies confirmed the stability-indicating capability of the method. The developed RP-HPLC method is sensitive, reproducible, and suitable for routine quality control analysis of Fosfestrol in pharmaceutical formulations.

## MODELING AND PREDICTING TABLETABILITY OF GINGEROL IN 3D-PRINTED ANTIHYPERTENSIVE TABLET

Ankita Satpathi1, Subhashree Sahoo1, Rashmi Prakash Palai2
1Department of Pharmaceutics, Kanak Manjari Institute of Pharmaceutical Sciences, Rourkela, Odisha
2All India Institute of Medical Sciences, Raipur, Chhattisgarh
ankitasatpathi15@gmail.com

This research work aims to prove the presence of Gingerol in ginger and to transform this biochemical as an active pharmaceutical ingredient in 3D-printed antihypertensive tablet. Hypertension, a vital global health concern involving physiological dysregulations, notably sympathetic nervous system over-activity, renin-angiotensin-aldosterone system (RAAS) imbalance, and renal dysfunction. The ethanolic extract of Gingerol from 100gm of Zingiber officinale (ginger) rhizome is characterized by using HPLC and FTIR spectroscopy to confirm its purity. HPLC was used to analyze 6-gingerols using C-8 reversed phase column eluted using mobile phase methanol: water (65:35, v/v) and UV detector at 282 nm. The recoveries of 6-gingerol was at 95.7 % from ginger with coefficient of variation 2.56 indicating reproducible result. This gingerol is converted to 3D-printed antihypertensive tablet applying wet granulation process, using excipients like gelatin, stearic acid, mannitol and sodium starch. Resulted in successful conversion of ginger powder into granules exhibiting excellent flow properties with Angle of Repose 29.67° and Carr Index 6.17%. The formation of a white colored, round shaped tablet met all the pharmacopoeial specifications, showing a mass of 301.06 mg, diameter of 10.15 mm, thickness of 3.27 mm. hardness of 5.5± 0.3 kg/cm2 and friability 0.48%, water absorption 16.23%, disintegration time 150 seconds and in vitro [6]-Gingerol release within 45 minutes suggesting high potential for quick absorption. The signature peaks of both free gingerol and additives were also observed in tablets. Hence, above designed tablets may render an optimal clinical solution to hypertension therapy in a patient-centric healthcare service.

**Keywords**: Gingerol, Antihypertensive, HPLC, FTIR, 3D-printed tablet.

## FORMULATION AND EVALUATION OF ORO-DISPERSIBLE TABLETS OF TENOFOVIR DISOPROXIL FUMARATE USING BANANA PEEL POWDER AS A NATURAL SUPERDISINTEGRANT

Ahmed Taha Ahmed Al-daghan, Preeti Karwa, Ayesha Syed,
Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bangalore – 560027.
A7795240464@gmail.com

The management of Human Immunodeficiency Virus (HIV) infection relies heavily on lifelong antiretroviral therapy; however, patients with dysphagia might find it challenging to take standard solid oral dosage forms, which may result in poor adherence.. This study aimed to develop and optimize oro-dispersible tablets (ODTs) of Tenofovir Disoproxil Fumarate (TDF) using eco-friendly banana peel powder as a natural superdisintegrant. ODTs were prepared by direct compression and optimized using a $3^2$ factorial design with two independent variables: mannitol concentration and banana peel powder concentration (three levels each), producing nine batches (F1–F9). Powder blends were characterized for flow and compressibility (angle of repose, Carr's index, Hausner ratio, porosity) and compressed tablets were evaluated for weight variation, hardness, friability, wetting time, disintegration time, water absorption ratio, and in vitro drug release (30 min). Design-Expert® software selected formulation F5 as optimal. F5 exhibited rapid disintegration (16 s), short wetting time (12 s), high water uptake, and achieved 89% cumulative drug release within 30 minutes. All evaluated pre- and post-compression parameters were within acceptable pharmacopeial limits. Short-term stability studies at room temperature for one month revealed no significant changes in physical appearance, drug content, disintegration time, or dissolution profile. These results indicate that banana peel powder is an effective, sustainable natural superdisintegrant for TDF ODTs, offering a patient-friendly dosage form to improve administration and adherence in dysphagic HIV patients.

**Keywords**: Tenofovir Disoproxil Fumarate, Oro-dispersible tablets, Banana peel powder, Natural superdisintegrant, Factorial design, Direct compression

## PREPARATION, CHARACTERIZATION OF MESOPOROUS POLYDOPAMINE NANOPARTICLES LOADED WITH PIPERONYLIC ACID AND EVALUATING INVITRO HEPATOPROTECTIVE EFFECT USING HEP G 2 CELL LINE

Venumadhuri R a, Dr.Juturu Mastanaiah b
aDepartment of Pharmacology,
Creative Educational Society's College of Pharmacy, Affiliated to Jawaharlal Nehru Technological University Anantapur, Kurnool and Research scholar, Department of Pharmaceutical sciences, Jawaharlal Nehru Technological University, Anantapur, Ananthapuramu, Andhra Pradesh, India
Department of Pharmacology, Balaji College of Pharmacy, Anantapuramu, Affiliated to Jawaharlal Nehru Technological University, Anantapur, Ananthapuramu, Andhra Pradesh, India.

Bioactive compounds derived from plants that have a vast of health-promoting properties are termed to as phytochemicals. In contrast, owing to their poor solubility, stability, bioavailability, and target selectivity, these compounds are of uncertain therapeutic use. The solubility, bioavailability, and pharmacokinetics of phytochemicals can all be improved by nano formulations in a number of ways (e.g., by reducing particle size). Targeted and regulated medication release can be achieved by modifying nanocarriers, especially mesoporous carriers. This study employed mesoporous polydopamine (MPDA) as a vehicle for the hepatoprotective potential evaluation of piperonylic acid. Mesoporous polydopamine nanoparticles loaded with piperonylic acid were prepared and characterized for its particles size, zeta potential, PDI, FTIR and SEM. Its effects on HepG2 proliferation inhibition were assessed using the MTT test. The results indicated that mesoporous polydopamine nanoparticles loaded with piperonylic acid inhibited the proliferation of HepG2 cells in a dose dependent manner.

**Keywords**: Mesoporous polydopamine nanoparticles, piperonylic acid, Hep G2 cell line

**PC-879**

## EFAVIRENZ AND LAMIVUDINE COFORMULATED IN BILAYERED TABLETS: A NOVEL APPROACH FOR DAILY HIV TREATMENT

Sri Sai Vasanthi Siriki, Satyalakshmi Siragam, Srinivasa Rao Yarraguntla
Department of Pharmaceutics, Vignan Institute of Pharmaceutical Technology, Duvvada, Beside VSEZ, Visakhapatnam-530049, Andhra Pradesh, India.

This investigation aimed to design and assess bilayered tablets combining Efavirenz (EFV) and Lamivudine (LMV) for daily HIV treatment, balancing swift onset with prolonged drug release. EFV was incorporated into the immediate-release layer using superdisintegrants; LMV, meanwhile, was formulated into the controlled-release layer using hydrophilic polymers, specifically HPMC K100M and Carbopol 934P, to sustain prolonged plasma levels. Parameters for tablets before and after compression were assessed, encompassing hardness (5.2–5.8 kg/cm²), friability (less than 0.8%), weight deviation (±2%), and drug content (98.2–101.5%), all meeting the required pharmacopeial standards. In-vitro dissolution studies were carried out using a USP type II paddle apparatus in a phosphate buffer solution with a pH of 7.4, a temperature of 37 ± 0.5 °C, and a stirring speed of 100 rpm over a 24 hr. Within 30 min, the immediate-release layer of EFV released 97.1 ± 1.3% of its

ISBN: 978-81-980623-8-3

content, while over the course of 24 hrs, the controlled-release layer of LMV exhibited 92.6 ± 2.0% release, following the Higuchi model ($R^2$ = 0.985) with non-Fickian diffusion (n = 0.61). This formulation enables once-daily dosing, enhances patient adherence, and sustains consistent plasma drug concentrations, underscoring its potential for effective HIV management.

The development of fast-dissolving oral thin films (OTFs) offers an innovative drug delivery system for enhancing patient compliance, particularly in pediatric and geriatric populations. This study aimed to formulate and evaluate an oral thin film containing Vitamin C (ascorbic acid) as a model active ingredient. Each 2 × 2 cm film was designed to deliver 100 mg of ascorbic acid, prepared by solvent casting technique on a laboratory scale. The formulation incorporated hydroxypropyl methylcellulose (HPMC E15) as the primary film-forming polymer, propylene glycol as plasticizer, sodium citrate as buffering/stabilizing agent, and suitable sweetener and flavoring agents for palatability. The casting solution was prepared under controlled temperature and light conditions to minimize degradation of ascorbic acid, and poured onto leveled glass plates to obtain uniform films. Post-drying, films were cut into individual doses and subjected to physicochemical and mechanical evaluation. The films demonstrated smooth texture, flexibility, and uniform thickness within the acceptable range (50–150 µm). Disintegration studies in simulated saliva (pH 6.8, 37 °C) confirmed rapid disintegration within 30–60 seconds, while dissolution testing revealed ≥80% drug release within 5 minutes. Drug content analysis using UV spectrophotometry confirmed uniformity, with values within 95–105% of the label claim. The prototype films showed promising stability under short-term storage when protected from light and moisture using aluminum foil pouches. Overall, the developed Vitamin C OTFs illustrate a patient-friendly dosage form with potential application in nutritional supplementation and rapid therapeutic delivery, highlighting their suitability for exhibition and further scale-up studies.

**Keywords**: Oral thin film, Ascorbic acid, Fast-dissolving dosage form, Solvent casting, Patient compliance

**DEVELOPMENT OF FAST RELEASE FORMULATION OF FENOFIBRATE USING FLUIDIZED BED PROCESSING TECHNOLOGY**

Vipin Deshmukh, Nimita Manocha, Zahid Husain
Indore Institute of Pharmacy, Indore, Madhya Pradesh, India- 453331
vipindeshmukh87@gmail.com

Fluidized bed processing technology is a very efficient way to apply a uniform layer of shell material onto solid particles. This method utilizes airflow to suspend and process particles, enhancing efficiency in these processes. The present study was aimed to utilize Fluidized bed processing technology in manufacturing of solid dispersion of poorly water soluble drug Fenofibrate and evaluating the dissolution behaviour of pure fenofibrate and further investigating the effect of solid dispersion on its crystalline characteristics and dissolution rate. Solid dispersion of Fenofibrate prepared using Fluidized Bed Processor (Make- P+am Glatt) was compressed into tablets and subjected to dissolution testing to assess its release profile. The dissolution studies were carried out using a USP Type II (paddle) Electrolab dissolution apparatus operated at 50 rpm in 0.75% sodium lauryl sulphate (SLS) aqueous solution maintained at 37 ± 0.5 °C. The results indicated that pure fenofibrate exhibited a slow and limited dissolution rate due to its hydrophobic and crystalline nature. To understand its solid-state properties, X-ray diffraction (XRD) analysis was performed. The X-ray diffractogram of pure fenofibrate displayed intense and sharp peaks at 14°, 17°, and 22°, confirming its highly crystalline structure. However, Diffraction patterns of drug-carrier physical mixture shows lesser degree of crystallinity and lesser number of characteristic peak of fenofibrate. The pattern of solid dispersion was completely diffused indicating a new amorphous solid phase in solid dispersion, which could potentially enhance its bioavailability and therapeutic efficacy in oral dosage forms.

**Keywords**: Fenofibrate, Hydrophobic, X-ray diffraction, Fluidized bed processing, P+am Glatt, Solid dispersion

**PC-882**

**FORMULATION AND OPTIMIZATION OF OXALIPLATIN SOLID LIPID NANOPARTICLES**

G.Shanmukhi Aarthi, K.Rajyalakshmi
Department of Pharmaceutics, Bapatla college of Pharmacy, Bapatla.

The present research reports the beneficial effects of enteric coated solid lipid nanoparticles for pH sensitive colon targeted delivery of oxaliplatin (OXA) for treating colorectal cancer. OXA encapsulated SLNs (OXA-SLNs) were prepared by solvent emulsification method and optimized using box-Behnken experimental design. The optimized OXA-SLNs were used for preparation of enteric coated OXA-SLNs (E-OXASLNs).The E-OXA-SLNs were then characterized for their particle size and surface morphology. The drug release from E-OXA-SLNs was observed at the basic pH of the colon. In addition, the E-OXA-SLNs exhibited greater cytotoxicity on colorectal cancer cells in vitro when compared to naive OXA. In conclusion, the E-OXA-SLNs are efficient carriers for improved efficacy and site specificity of OXA.

**Keywords**: Oxaliplatin, colorectal cancer, pH sensitive, enteric coating, solid lipid nanoparticles.

**PHARMACEUTICAL TECHNOLOGY AND TARGETED DRUG DELIVERY SYSTEMS: ENHANCING EFFICACY AND SAFETY.**

M Sri Lakshmi pallavi .
Pharmaceutical Technology, A.S.N. pharmacy college, Burripalem, Tenali, Guntur district, Andhra Pradesh,India – 522201
srilakshmipallavimunagala@gmail.com

Pharmaceutical technology has transformed modern therapeutics through the development of targeted drug delivery systems (TDDS). Unlike conventional dosage forms, TDDS focus on delivering drugs precisely to the site of action, thereby improving therapeutic outcomes while minimizing systemic toxicity. The aim of this study is to evaluate the role of TDDS in enhancing drug therapy. The objectives include assessing novel carriers, targeting mechanisms, and comparing their advantages over conventional systems in terms of safety and efficacy. A systematic review of recent literature was carried out, focusing on nano carriers such as liposomes, polymeric nanoparticles, and dendrimers. Controlled-release formulations and ligand-mediated targeting approaches were analyzed for their pharmacokinetic benefits and therapeutic effectiveness. Findings indicate that TDDS significantly improve bioavailability, prolong circulation time, and provide controlled and site-specific drug release. Nano carriers enhance drug stability and reduce dosing frequency, while ligand-conjugated systems improve selectivity through receptor-mediated targeting. These advancements collectively reduce side effects and increase patient compliance. Targeted drug delivery systems mark a major advancement in pharmaceutical technology, offering precision therapy with higher efficacy and lower toxicity. Continued research in nanotechnology and bio molecular engineering is expected to further expand their applications, supporting the future of personalized medicine.

**Keywords**: Nano carriers, Liposomes, controlled release, Ligand targeting, personalized Medicines.

**PC-884**

**FORMULATION AND EVALUATION OF SUSTAINED RELEASE MATRIX TABLET OF VENLAFAXINE HCL USING HYDROPHILIC AND HYDROPHOBIC POLYMERS**

Kadam Arati Sambhaji, Giramkar Ankita Arjun, Khedkar Amol Navnath
Saikrupa Institute of Pharmacy, Ghargaon, Shrigonda, Ahilyanagar, Maharashtra, India 413728

The objective of this study was to develop and evaluate sustained release (SR) matrix tablets of Venlafaxine Hydrochloride, a selective serotonin and norepinephrine reuptake inhibitor (SSNRI), to reduce dosing frequency and improve therapeutic outcomes. Venlafaxine HCl has a relatively short biological half-life (approximately 5 hours), necessitating multiple daily doses. Matrix tablets were formulated using hydrophilic polymer Hydroxypropyl Methylcellulose (HPMC K100M) and

ISBN: 978-81-980623-8-3

hydrophobic polymer Ethylcellulose (EC) in varying ratios to modulate drug release. The tablets were prepared by wet granulation and evaluated for physicochemical parameters including hardness, friability, weight variation, thickness, and drug content uniformity. In vitro dissolution studies were conducted using USP Type II dissolution apparatus in pH 1.2 HCl buffer for 2 hours followed by phosphate buffer pH 6.8 for the remaining 22 hours, simulating gastrointestinal transit. Drug release kinetics were analyzed using mathematical models such as zero-order, first-order, Higuchi, and Korsmeyer-Peppas to understand the mechanism of release. Formulations containing a balanced combination of HPMC and EC demonstrated prolonged drug release up to 24 hours with initial burst minimization and controlled release thereafter. The optimized formulation followed zero-order kinetics ($R^2 > 0.99$) with anomalous (non-Fickian) diffusion mechanism, indicating a combination of diffusion and erosion processes. These findings suggest that the synergistic use of hydrophilic and hydrophobic polymers can effectively sustain the release of Venlafaxine HCl, offering a promising strategy for once-daily oral administration and enhanced patient compliance.

**Keywords**: Venlafaxine Hydrochloride, sustained release, matrix tablet.

## FORMULATION AND OPTIMIZATION OF HERBAL OINTMENT PREPARED FROM CHROMOLAENA ODORATA

Fousiya K, Harsha K and Jesna
Department of Pharmacognosy, Nehru College of Pharmacy, Thrissur, Kerala, India – 680588
fousiyak101@gmail.com

The present study focuses on the formulation and optimization of herbal ointment prepared from Chromolaena odorata (Asteraceae), a medicinal plant widely known for its antioxidant, anti-inflammatory, antimicrobial, and wound-healing properties. The plant material was collected, authenticated, and subjected to pharmacognostical, physicochemical, and phytochemical evaluations. Ethanolic extraction using Soxhlet apparatus yielded the highest percentage of bioactive constituents, confirmed through qualitative phytochemical screening and TLC profiling. Ointment formulations were prepared by fusion method using emulsifying wax, white soft paraffin, liquid paraffin, and varying concentrations of C. odorata extract. The prepared batches were evaluated for organoleptic characteristics, pH, spreadability, and stability. Among the six preliminary formulations, F4 was identified as the most suitable based on optimum pH and spreadability values. Further optimization was performed using a $2^2$ factorial design with Minitab software to study the effect of emulsifying wax and soft paraffin concentrations on formulation characteristics. The optimized formulation demonstrated desirable consistency, stability, and therapeutic potential, validating the traditional use of C. odorata for wound healing and skin infections. This study highlights the potential of Chromolaena odorata as a natural, cost-effective, and safe herbal ointment base, supporting its future development into standardized topical phytopharmaceutical products.

**Keywords**: Chromolaena odorata, antioxidant, anti-inflammatory, wound-healing

## A PERCEPTIVE STUDY ON THE IMPORTANCE OF STORING MEDICINES AT THE REQUIRED TEMPERATURE AND ITS UNDERSTANDING AMONG COMMUNITY PHARMACISTS.

Vatsala S. Sinha, Alka C. Moje, Nishant B. Awandekar, Milind J. Umekar
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee, Nagpur-441002
vatsalasinha1326@gmail.com

Community pharmacists are one of the critical link in ensuring safe and effective medicine storage and supply. They are supposed to maintain proper storage conditions required for the medicines, particularly antibiotics, vaccines, sera etc. However, extreme climatic variations, particularly summer temperatures that often exceed 40°C, pose significant challenges for medicines that require controlled storage between 15°C and 25°C. With over 70% of medicines being temperature-sensitive, improper storage may reduce potency and compromise patient health if left unnoticed. So a cross-sectional survey was conducted across 62 pharmacies, of which 53 participated actively. Analysis revealed that most pharmacies stored medicines above the recommended range. While 86.8% of respondents agreed that elevated temperatures might impact potency, a notable proportion remained uncertain or unaware of the risk. It also showed that more than 86% agreed that storing medicine constantly at an elevated temperature might definitely affect its potency. The study emphasized the need for more awareness that should be made so that the community pharmacist will serve the society in an effective manner by taking into consideration all the good storage practices. Adopting standardized storage practices will improve the reliability of medicine distribution and ultimately safeguard public health.

**Keywords**: Community Pharmacy, Storage, Medicine, Temperature, Potency.

## SYNTHESIS AND CHARACTERIZATION OF NITROFURANTOIN COCRYSTALS: IMPROVED SOLUBILITY AND DISSOLUTION PROFILE

Sandip Honmane, Omkar Gouraje
Department of Pharmaceutics, Annasaheb Dange College of B Pharmacy, Ashta, Shivaji University, Kolhapur, Maharashtra, India 416301.
sandiphonmane@gmail.com

The limited aqueous solubility of numerous active pharmaceutical ingredients, particularly those categorized under the Biopharmaceutical Classification System (BCS) Class II and IV, poses a substantial obstacle to oral drug delivery and bioavailability. This study explores the potential of pharmaceutical cocrystals to enhance the solubility and dissolution profile of nitrofurantoin (NF), a BCS Class II antibacterial agent widely used for urinary tract infections. Succinic acid (SA), a pharmaceutically acceptable co-former, was selected to prepare NF cocrystals using the solvent evaporation method at varying molar ratios (1:1, 1:2, 1:3, and 2:1). Preformulation studies, including organoleptic evaluation, melting point determination, UV analysis, and solubility testing, were conducted to assess the impact of cocrystallization. Comprehensive solid-state characterization using FTIR spectroscopy, differential scanning calorimetry (DSC), and X-ray powder diffraction (XRPD) confirmed the formation of a new crystalline phase. The NF:SA (1:2) formulation exhibited the most significant improvement, achieving a solubility of 644 µg/mL, representing a more than threefold increase over the pure drug (195 µg/mL), and 99.84% drug release within 45 minutes, compared to 51.41% for NF alone. Characterization data indicated hydrogen bonding interactions, peak shifts, and reduced crystallinity, suggesting partial amorphization and the development of a distinct solid form. These results demonstrate that cocrystallization is an effective strategy for enhancing the dissolution and solubility of poorly water-soluble drugs. The optimized NF–SA (1:2) cocrystals formulation offers a promising approach for improving the oral bioavailability of NF and may be extended to other APIs with similar biopharmaceutical limitations.

**Keywords**: Cocrystals, poorly soluble drug, nitrofurantoin, Pharmaceutical crystal engineering, solubility etc.

## FORMULATION AND CHARACTERIZATION OF HERBAL ANTI-FUNGAL CREAM OF MORINGA OLEIFERA

Reena Sheoran, Chunender
Department of Pharmaceutical Sciences, Chaudhary Bansi Lal University, Bhiwani, Haryana, India -127031
reenasinghsheoran@gmail.com

In the current research the formulation of herbal cream using Moringa oleifera leaves extract is prepared and characterized for their anti-fungal properties. Extraction of Bioactive Compounds of Moringa using ethanol solvent in a Soxhlet extractor. The extract is incorporated into a base cream containing emollients, emulsifiers, and humectants to form six formulations of Oil in water (O/W) emulsion-based cream was formulated. Evaluation of the physicochemical properties of the formulated Cream. Investigation of the In-Vitro antifungal activity of the Moringa Oleifera cream. Determination of the shelf life and stability of Moringa Oleifera cream. The cream exhibited excellent physical and chemical stability, as well as a desirable texture, viscosity, and pH suitable for topical application. The largest zone of inhibition was produced by water and ethanol extract of Moringa oleifera against Saccharomyces cerevisiae. The formulation of herbal cream using Moringa oleifera leaves extract shows great potential as a natural, effective, and safe skincare product. The optimized formulation

ISBN: 978-81-980623-8-3

demonstrated excellent stability and therapeutic activity, making it a viable alternative to synthetic skincare products. Further research should focus on refining extraction techniques, optimizing concentration levels, and evaluating long-term stability and shelf life.

**Keywords**: Herbal Cream, Anti-Fungal, Moringa oleifera, Leaves.

**PC-889**

## MULTIPARTICULATE PHYTOSOMAL CO-DELIVERY OF QUERCETIN AND VITAMIN D: A NOVEL APPROACH FOR INTESTINAL BARRIER DYSFUNCTION

Manjula R, Nirmala, Prathibha C V
Department of Pharmaceutics, Oxbridge College of Pharmacy, Bangaluru, India 560091
manjulamanjusrp@gmail.com

Intestinal barrier dysfunction is increasingly recognized as a key factor in the development of gastrointestinal and systemic disorders such as inflammatory bowel disease and metabolic syndrome. Natural bioactives like Quercetin, a flavonoid with potent antioxidant and anti-inflammatory activity. Vitamin D a Secosteroid vital for calcium homeostasis and immune modulation have shown promising effects in maintaining gut integrity. Unfortunately, both face major challenges like poor water solubility and very low absorption when taken orally, which reduces their effectiveness.The present research focuses on the development of a colon-targeted dual Phytosomal Multiparticulate system of Quercetin and Vitamin D to overcome the limitations. Phytosomes of Quercetin and Vitamin D will be prepared by a nanotechnology-based method and optimized systematically using Design of Experiment (DOE) approach. The optimized formulations will be evaluated for particle size, zeta potential, drug-loading efficiency, stability, and release profile, designed for colon-targeted delivery. By colon-targeted delivery, this project is expected to improve bioavailability, stability, and combined therapeutic effects of Quercetin and Vitamin D. The work will not only provide a novel treatment option for intestinal barrier dysfunction but also highlight the value of natural, sustainable, and patient friendly therapies.

**Keywords**: Intestinal barrier dysfunction, Quercetin, Vitamin D, Secosteroid, Phytosomes, Colon-targeted delivery, Design of experiment.

## NANOSTRUCTURED SIMVASTATIN CUBOSOMAL GELS: ENHANCED TOPICAL DELIVERY AND ACCELERATED WOUND HEALING

Kothapalli Sandeepa,b, K. Sujanab
Department of Pharmaceutics, Sarojini Naidu Vanita Pharmacy Maha Vidyalaya, Hyderabad
Acharya Nagarjuna University, University College Of Pharmaceutical Sciences

This study investigates the formulation and evaluation of simvastatin-loaded cubosomal nanoparticles designed for topical wound healing applications. Cubosomes were prepared using glyceryl monooleate and poloxamer 407 via a top-down method and characterized for particle size, entrapment efficiency, and release properties. The optimized formulation demonstrated a nanometric particle size and high drug entrapment, ensuring sustained release of simvastatin. Incorporation into cubogels using agents such as HPMC and chitosan further improved the topical applicability, with the HPMC-based cubogel showing superior rheological behavior and permeability. The average particle size of the prepared simvastatin cubosomes was approximately 114 nm, ensuring optimal integration for topical delivery. The entrapment efficiency reached about 94%, supporting sustained and effective drug release. In vitro release and permeation studies showed that cubosomal gels provided significantly enhanced drug permeation through rat skin, with a flux value of 46.18 mcg/cm²/h for the cubogel versus 25.92 mcg/cm²/h for the free drug hydrogel. In vivo testing in a rat wound model demonstrated noticeably higher wound closure percentages in the group treated with simvastatin cubosomal gel (92.3% after 11 days) compared to plain cubogel (69.2%) and free simvastatin hydrogel (77.0%). Histopathological analysis confirmed improved re-epithelialization and granulation tissue formation in wounds treated with the simvastatin cubosomal gel. These findings support the potential of cubosomal nanocarriers as effective vehicles for the topical administration of simvastatin, offering promising advances in wound management therapies.

## FORMULATION, OPTIMIZATION AND EVALUATION OF B-CYCLODEXTRIN-BASED NANOSPONGES OF DIACEREIN FOR SUSTAINED DELIVERY AND ENHANCEMENT OF ANTIDIABETIC ACTIVITY

Zahid Husain, Shivani Rai Paliwal, Nimita Manocha
Indore Institute of Pharmacy, Indore, Madhya Pradesh, India -453331
zahidansari7570@gmail.com

β-Cyclodextrin (βCD), a cyclic oligosaccharide, was employed to formulate nanosponges (NSPs) aimed at enhancing the solubility and therapeutic performance of diacerein (DCN). The clinical use of DCN by the oral route is limited because of its poor aqueous solubility, low bioavailability, and dose-dependent gastrointestinal side effects. In the present work, βCD-based nanosponges were formulated by using diphenyl carbonate (DPC) as a crosslinking agent, and the formulation process was systematically optimized through a Quality by Design (QbD) strategy employing the Box–Behnken Design (BBD). The optimized formulation showed a mean particle size of 336.6 ± 5.3 nm, zeta potential –22.4 ± 1.3 mV, polydispersity index 0.21 ± 0.03, production yield 65.31 ± 3.8%, entrapment efficiency 87.18 ± 4.1%, and drug loading 29.06 ± 3.4%. Solubilization efficiency demonstrated a ~9.9-fold enhancement in aqueous solubility of DCN. Morphological examination by SEM revealed a sponge-like porous structure, while FTIR, PXRD, and DSC studies confirmed successful entrapment of DCN without significant chemical interactions. In vitro dissolution studies indicated a controlled drug release extending up to 24 hours, and stability testing confirmed good stability under refrigerated storage. Pharmacodynamic evaluation in alloxan-induced diabetic rats exhibited a considerable decrease in blood glucose levels, and histopathological findings confirmed regeneration of pancreatic β-cells. These findings establish βCD-based nanosponges as a potential nanocarrier system for improving oral bioavailability and providing sustained antidiabetic efficacy of diacerein, suggesting significant promise for its application in diabetes management.

**Keywords**: β-Cyclodextrin, Nanosponges, Diacerein, QbD, Diabetes Mellitus

## EVALUATION OF LIPSTICKS FOR COMPLIANCE WITH BIS STANDARDS: A COMPARATIVE STUDY

Deepak sharma1, Manvi singh1, Vijay bhalla1
1Department of Pharmaceutics, SGT College of Pharmacy, SGT University-122505.
ds1971di@gmail.com

The Indian cosmetic industry is experiencing rapid growth, with the market valued at USD 8.1 billion in 2023 and projected to reach USD 18.4 billion by 2032. Among cosmetic products, lipsticks represent a significant and widely used category. This study was conducted to assess the compliance of various lipstick brands with the standards set by the Bureau of Indian Standards (BIS). A total of 102 lipstick samples were collected from 17 different brands available in the Indian market. These samples underwent rigorous physical and chemical analysis, based on the testing procedures outlined in BIS specifications. The analysis focused on key parameters such as consistency, melting point, pH, heavy metal content, and overall safety. Results revealed that the majority of tested lipstick samples met the BIS requirements, demonstrating satisfactory compliance across all tested parameters. The findings suggest that Indian lipstick manufacturers generally adhere to regulatory norms, ensuring consumer safety and product quality. However, the study emphasizes the continued need for regular quality checks and regulatory oversight due to the increasing consumer demand and diversity in product formulations. This comparative evaluation provides valuable insight into market trends and supports efforts toward standardization and safe cosmetic use.

**Keywords**: Lipsticks, BIS standards, cosmetic evaluation in India, standardisation, safe.

**DEVELOPMENT OF CUSTOMIZED 3D-PRINTED BILAYER TABLETS FOR CONTROLLED DRUG DELIVERY IN NEURODEGENERATIVE DISORDERS**

Jeevandeep Mishra, Shailendra Chouhan, Nimita Manocha
Indore Institute of Pharmacy, Indore, Madhya Pradesh, India- 453331
mishrajeevandeep03@gmail.com

Dementia affects over 55 million people worldwide, with an estimated 10 million new cases annually, posing significant challenges for effective pharmacotherapy. Conventional oral dosage forms often fail to provide sustained therapeutic levels, leading to fluctuating plasma drug concentrations and poor patient compliance. This study aims to develop customized 3D-printed bilayer tablets for controlled drug delivery in dementia, combining an immediate-release layer for rapid symptom management and a sustained-release layer to maintain stable plasma concentrations. The tablets were fabricated using fused deposition modeling (FDM) 3D printing, optimizing printing parameters such as layer height, infill density, and nozzle temperature. Two commonly prescribed anti-dementia drugs, Donepezil (10 mg) and Memantine HCl (20 mg), were incorporated into separate layers. Physicochemical characterization revealed tablets with uniform weight variation (±2.1%), hardness of 140–160 N, and friability below 0.8%, indicating robust mechanical stability. In vitro dissolution studies showed an initial 35–40% drug release within 1 hour from the immediate-release layer, followed by sustained release of 85–90% over 12 hours from the controlled-release layer, achieving biphasic drug release. Stability studies over 3 months at 40°C/75% RH demonstrated minimal drug degradation (<3%), confirming formulation stability. The results indicate that 3D-printed bilayer tablets can achieve precise, patient-specific dosing and controlled release profiles, potentially improving therapeutic efficacy and adherence in dementia patients. This approach exemplifies a step toward personalized neuropharmacotherapy, leveraging additive manufacturing to address the limitations of conventional oral dosage forms in neurodegenerative disorders.

**FORMULATION AND EVALUATION OF ATENOLOL SUCCINATE TRANSDERMAL PATCHES**

Nikhitha Mallampalli, Pisipati Aparna
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
nikhithamallampalli74@gmail.com

Use of TDDS provides a non-invasive method for drug delivery that enhances bioavailability, eliminates first-pass metabolism, and facilitates the release of controlled substances. Atenolol succinate, a cardio-selective beta-blocker, is frequently prescribed to manage hypertension and angina pectoris. The oral administration of drug results in low bioavailability (50%) due to first-pass metabolism and there by a short half-life, necessitating frequent dosing. By using a transdermal patch that contains atenolol, these limitations can be addressed by providing consistent drug delivery, better patient compliance, and reduced dosing frequency. In this work atenolol transdermal patches were prepared for long term use and controlled delivery. Objectives are, to manufacture transdermal patches of atenolol by using polymers, viz., HPMC, Eudragit as Penetrating enhancer, as plasticizer. The prepared patches were characterized for thickness, moisture content folding endurance and invitro drug release using Franz diffusion cell. The patches for evaluated for accelerated short term stability studies. The physicochemical parameters of prepared transdermal atenolol succinate patches, exhibited satisfactory properties and the invitro release was observed for 24hours. All the prepared patches demonstrated good stability, mechanical strength and drug release. These results showed a promising option for delivering atenolol in a sustained release form for an effective treatment for hypertension when compared to oral administration.

**Keywords**: Atenolol succinate, transdermal patch, TDDS, hypertension.

**PC-895**

**FORMULATION AND EVALUATION OF ASPIRIN ORODISPERSIBLE FILMS FOR POST-STROKE DYSPHAGIA: A PRELIMINARY INVESTIGATION**

Preeti Sen
University Institute of Pharmacy, Pt. Ravishankar Shukla University, Raipur, Chhattisgarh, India
preetisen613@gmail.com

Aspirin (Acetylsalicylic Acid, ASA) is a key antiplatelet agent used for immediate loading and secondary prevention of ischemic stroke. Dysphagia affects up to 50% of stroke survivors, leading to poor medication adherence and increased risk of recurrent stroke. Conventional solid oral dosage forms are often difficult to swallow in these patients, emphasizing the need for patient-friendly alternatives. This study aimed to formulate and evaluate Orodispersible Films (ODFs) of ASA for rapid, water-free administration. Films were prepared using the solvent casting method, with three formulations (F1–F3) incorporating different hydrophilic polymers, including hydroxypropyl methylcellulose (HPMC E5), polyethylene oxide (PEO), and Pullulan, and propylene glycol as a plasticizer. Taste-masking agents were included to improve palatability. The characterization included in vitro disintegration in simulated saliva, folding endurance, drug content uniformity, and preliminary stability testing. The optimal formulation was identified based on rapid disintegration, acceptable mechanical strength, uniform drug distribution, and effective taste masking. The results suggest that the optimized ODF provides a safe, convenient, and patient-centric dosage form for post-stroke patients with dysphagia. By enabling fast and reliable administration of ASA without water, this delivery system has potential to improve medication compliance and therapeutic outcomes in stroke survivors.

**DESIGN, DEVELOPMENT AND CHARACTERIZATION OF SELF-MICROEMULSIFYING DRUG DELIVERY SYSTEM CONTAINING RUPATADINE FUMARATE**

Jaydeep Patel1, Hemang Joshi2, MM Soniwala3, A V Dudhrejiya4, Sapana Patel5
1,2,3,4B K Mody Government Pharmacy College, Rajkot,Gujarat.
5Regional Food Laboratory, Food and Drug Control Administration, Gujarat.
Patel_jaydeep1@gtu.edu.in

The objective of this research work was to formulate the SMEDDS of Rupatadine fumarate, the drug with extensive metabolism and poor in-vitro dissolution. The SMEDDS formulated aimed for the enhancement of the dissolution and that may potentially improve its therapeutic efficacy. Based on the solubility and emulsification capacity, a preliminary screening was conducted to choose the best oil, surfactant, and co-surfactant. The ternary phase diagram was constructed using the best available oil, surfactant, and co-surfactant. The area with high emulsification was indicated by the ternary plot. To further understand the impact of independent factors on the answers, optimization was carried out using a simplex centroid design based on the data. There was a remarkable correlation between the globule size and the percentage CDR. The improved batch underwent additional characterisation procedures, including transmittance, dilution, cloud point detection, and self-emulsification. The SMEDDS formulation prepared using oleic acid (oil), Acrysol K160 (surfactant) and Transcutol HP (co-surfactant). The utilization of the simplex centroid design as design of experiment provided optimized constrained for batch preparation. Batch R3 have selected for further characterization has release and globules in desired range. The dispersibility and self-emulsification time was found to be efficient belonging to the grade A. The SMEDDS showed clear transparent microemulsion and its cloud point was obtained to assess the thermal stability. The in-vitro dissolution of the selected SMEDDS formulation showed increase in the dissolution in comparison with Pure drug with 10 folds increase.

**Keywords**: Self Micro Emulsifying Drug Delivery (SMEDDS), Oleic acid, Acrysol K160, TranscutolHP, Rupatadine Fumarate

**GASTRO-RETENTIVE MUCOADHESIVE MICROSPHERES OF REPAGLINIDE ENRICHED WITH CHITOSAN FOR ENHANCED ANTI-DIABETIC EFFICACY**

Neha Gode, Mrunal Deshmukh

ISBN: 978-81-980623-8-3

Datta Meghe College of Pharmacy, Salod (H), Datta Meghe Institute of Higher Education and Research (D.U), Wardha-442002
godeneha9@gmail.com

Repaglinide (RPG) exhibits rapid absorption from the gastrointestinal tract after oral administration due to its low log P value. To overcome this, mucoadhesive microspheres of RPG were developed using the ionotropic gelation method with biodegradable polymers such as guar gum, chitosan, and fenugreek seed mucilage. These microspheres were characterized and evaluated through in vitro studies, followed by an oral glucose tolerance test in animals. Scanning electron microscopy revealed that the microspheres were smooth, spherical, and pore-free. The optimized formulation showed an average particle size of 300 µm, a polydispersity index (PDI) of 0.349, and a high positive zeta potential of 38.4 mV. The formulation also demonstrated a percentage yield of 87.04% and a swelling index of 90.65%, with 95.20% drug release over 10 hours. Furthermore, the microspheres achieved an entrapment efficiency of 94.86 ± 4.25%. In vivo results indicated that the optimized RPG microspheres significantly reduced glucose-induced hyperglycemia (2 g/kg) compared to the marketed RPG formulation (0.25 mg/kg) within 2 hours of oral administration, while maintaining controlled blood glucose levels for up to 10 hours. Overall, the formulation showed improved anti-diabetic efficacy.

**Keywords**: Repaglinde, chitosan, fenugreek, guar gum, characterization

## DRUG UTILIZATION PATTERN OF NSAIDS AND TRAMADOL IN SURGICAL WARDS: A PROSPECTIVE OBSERVATIONAL STUDY

Bhumika Tomar, Akhilesh Bilaiya, Swarangi Karangale
Sri Aurobindo Institue of Pharmacy, Indore, Madhya Pradesh-453555
tomarbhumika7@gmail.com

Effective postoperative pain management is essential for optimal recovery. Non-steroidal anti-inflammatory drugs (NSAIDs) and Tramadol are commonly used analgesics in surgical settings, each with unique efficacy and safety profiles. This prospective observational study aimed to evaluate the prescribing patterns, effectiveness, and adverse effects of NSAIDs and Tramadol among 75 surgical patients at a tertiary care hospital in Indore, India. Data were collected over six months using structured case record forms and pain score questionnaires. Diclofenac was the most frequently prescribed NSAID, followed by Paracetamol and Tramadol. Tramadol provided faster initial pain relief, while NSAIDs showed consistent efficacy over 72 hours. Adverse effects such as constipation and nausea were more common with NSAIDs. The findings support rational, multimodal pain management tailored to individual patient profiles.

**Keywords**: NSAIDs, Tramadol, Pain Management, Drug Utilization, VAS, Postoperative Analgesia.

**PC-899**

## DEVELOPMENT AND EVALUATION OF GASTRO-RETENTIVE EXTENDED RELEASE FORMULATIONS OF LANSOPRAZOLE

Gangumolu Thanmaya Swathi, Pisipati Aparna
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
gangumoluswathi@gmail.com

The present study was undertaken to design and evaluate gastro-retentive and extended release formulations of Lansoprazole, a benzimidazole-based proton pump inhibitor extensively prescribed for gastric and duodenal ulcers. Since Lansoprazole is acid-labile and undergoes rapid degradation in the stomach, site-specific delivery to the intestine is essential for maintaining therapeutic efficacy. Within the gastro-retentive drug delivery system (GRDDS) framework, orally disintegrating tablets (ODTs) containing enteric-coated granules were prepared using pH-sensitive polymers such as HPMC E5, Eudragit L30 D-55. Among eight formulations, demonstrated an optimized dissolution profile with delayed release behavior, governed by zero-order kinetics and a Fickian diffusion-controlled mechanism. Extended release enteric-coated pellets of Lansoprazole were formulated via solution-suspension layering in a fluid bed processor. The process included sequential drug loading, sub-coating, enteric coating, and lubrication, yielding 5 formulations. Evaluation of physicochemical and acid resistance. Dissolution, friability, and content uniformity identified as the most suitable batch, confirming pharmaceutical equivalence, stability, and cost-effectiveness. Overall, the study highlights that optimized GRDDS-based ODTs and extended release enteric-coated pellet formulations of Lansoprazole not only improve stability and therapeutic efficacy but also enhance patient compliance, offering a cost-effective strategy for the management of gastric and duodenal ulcers.

**Keywords**: Proton pump inhibitor, Fickian diffusion, Encapsulation.

## NANO-FORMULATION AND EVALUATION OF MUCO-ADHESIVE BUCCAL PATCHES OF METRONIDAOLE FOR LOCALIZED ORAL THERAPY

Ahemad Asadulla Pathan, Md.Rayees Ahmad, Aslam Tamboli, Shaikh Gazi, Pathan Muzakkir.
Dept. of Pharmaceutical Chemistry, RP College of Pharmacy, Gadpati, Alani, Osmanabad.MH, 413501

The buccal mucosa provides an attractive and promising route for localized drug delivery due to its high vascularization, easy accessibility, and ability to bypass first-pass metabolism. Metronidazole, a widely used antimicrobial for oral infections such as gingivitis, periodontitis, and dental abscesses, requires frequent topical application in conventional forms like gels and rinses, which often leads to poor patient compliance and fluctuating drug levels. In this study, muco-adhesive buccal patches of Metronidazole were formulated using chitosan as polymeric carriers. This study demonstrates a simple and effective approach to develop Metronidazole-loaded muco-adhesive buccal patches for localized oral delivery. The formulation strategy, involving biocompatible polymers and solvent-casting techniques, ensures enhanced residence time, controlled drug release, and effective antimicrobial action, highlighting the potential of mucoadhesive buccal patches as an efficient alternative for oral infection management. Comprehensive characterization included physicochemical evaluation, thickness and weight uniformity, surface pH, swelling studies, muco-adhesive strength, and in-vitro drug release. Optimized patches demonstrated adequate muco-adhesion, Overall, research work demonstrates a simple and effective strategy to develop metronidazole-loaded muco-adhesive buccal patches for localized oral delivery. The formulation ensures enhanced residence time, controlled drug release, and effective antimicrobial action, highlighting the potential of muco-adhesive buccal patches as a viable alternative for the treatment of oral infections.

**Keywords**: Nano particle, Patches, Metronidazole, antimicrobial action.

## FORMULATION AND EVALUATION OF HERBAL SCALP SERUM CONTAINING PSIDIUM GUAJAVA LEAVES EXTRACT.

Vishal D. Lahane.

Hair plays a vital role in human aesthetics, with healthy hair defined by its shine, smoothness, volume, and the absence of scalp issues such as dandruff or thinning. Maintaining hair health requires both cosmetic and therapeutic care, with the scalp being central to this process. The scalp, anatomically bordered by the face and neck, consists of five layers: skin, connective tissue, aponeurosis (Galea aponeurotica), loose areolar tissue, and pericranium. These layers support hair growth and overall scalp health. Proper scalp care, including exfoliation, helps remove dead skin cells and supports regeneration. Herbal scalp serums have emerged as multifunctional solutions for common scalp and hair concerns. These lightweight formulations—available in oil-based, water-based, spray, and silicone-based forms—deliver active ingredients to treat conditions such as dandruff, alopecia, frizz, and heat or color damage. This study focuses on the formulation and evaluation of a herbal scalp serum using Psidium guajava (guava) leaves, recognized for their rich phytochemical composition and potential hair benefits. The research included collection, identification, and authentication of the plant, followed by preparation of its ethanolic extract. A detailed pharmacognostic profile was developed, and preliminary phytochemical screening was performed. The formulated serum was evaluated for various parameters such as pH, viscosity, spreadability, and stability. The objective of this study is to develop an effective, natural, and multifunctional herbal serum offering a holistic approach to scalp and hair care, combining cosmetic innovation with therapeutic benefits.

**Keywords**: Scalp health, herbal scalp serum, Psidium guajava, hair growth, ethanolic extract.

**NANO-FORMULATION AND EVALUATION OF A POLYHERBAL OIL FOR ANTI-INFLAMMATORY AND ANALGESIC ACTIVITY**

Hagare Yash Vijaykumar, Nirwane Aboli, Md. Rayees Ahmad, Shaikh Gazi, Pathan Muzakkir
Dept. Of Pharmacognosy, RP College of pharmacy, Ganapati, Alani, Dharashiv, MH, 413501

Inflammation and pain are among the most prevalent symptoms encountered in a range of diseases and injuries. The development of novel COX-2 inhibitors with both analgesic and anti-inflammatory efficacy, while minimizing gastrointestinal, renal, and cardiovascular toxicity, is crucial for patients suffering from chronic pain and inflammatory conditions. This research aims to develop and evaluate a polyherbal oil formulation containing Sesamum indicum (sesame oil) and Ricinus communis (castor oil), along with other traditional medicinal plants, for the treatment of osteoarthritis. The formulation comprises natural ingredients, such as Curcuma amada (mango turmeric), and base oils including sesame, castor, and mustard, with Cinnamomum camphora (Bhimseni Kapoor) serving as an aromatic component. The extraction process was optimized to preserve bioactive compounds, particularly those with anti-inflammatory and analgesic properties. Physicochemical evaluation was conducted, assessing organoleptic properties, pH, viscosity, spreadability, and nanoparticle size analysis, followed by preliminary skin irritation testing. The resultant yellowish-green oil exhibited optimal spreadability and a pH of 5–6, making it suitable for topical application. The prepared nano-formulation demonstrated good physical stability and did not cause skin irritation in preliminary tests. Phytochemical screening confirmed the presence of constituents such as flavonoids, alkaloids, and terpenes. Overall, the developed formulation presents a promising therapeutic option for the management of spondylitis and osteoarthritis, leveraging the synergistic effects of traditional medicinal plants in an optimized delivery system.

**Keywords**: Osteoarthritis, Spondylitis, Muscle strains, Patellofemoral pain syndrome, Traditional medicine, Anti-inflammatory, Arthritis.

**FORMULATION AND EVALUATION OF MELOXICAM LIQUISOLID COMPACTS**

D.DIVYA SATYA SAI VIHARI

Meloxicam, a BCS Class II drug, suffers from poor aqueous solubility, resulting in limited dissolution and variable bioavailability. The present study aimed to enhance the dissolution of meloxicam using the liquisolid compact technique, which employs a non-volatile solvent system and porous carriers to convert liquid medication into a free-flowing, compressible powder. Meloxicam (5% w/w in PEG 400) was incorporated into microcrystalline cellulose (Avicel PH 102) as carrier and Aerosil as coating material in a 15:1 ratio. Sodium starch glycolate (1% w/w) was added as superdisintegrant. The prepared liquisolid systems were compressed into tablets and evaluated for pre- and post-compression parameters including flow properties, hardness, friability, weight variation, disintegration, and in vitro dissolution. The liquisolid powder blend exhibited good flow properties (angle of repose: 15.45°). However, the compressed tablets showed suboptimal mechanical properties (hardness: 2 kg/cm$^2$; friability: 7.14%). Weight variation also failed to comply with IP standards. The average disintegration time was 12.8 minutes. Dissolution studies revealed cumulative drug release of 1.46% for liquisolid tablets compared to 16.04% for pure meloxicam, indicating that extended disintegration limited drug release. Although liquisolid compacts are a promising approach for improving dissolution of poorly soluble drugs, in this study meloxicam formulations showed inferior dissolution compared to pure drug, primarily due to prolonged disintegration time and weak mechanical strength. Optimization of carrier–coating ratio, solvent selection, and superdisintegrant level is required to achieve improved performance.

**Keywords**: Meloxicam, Liquisolid compact, Dissolution enhancement, BCS Class II drugs, PEG 400.

**PC-904**

**FORMULATION AND EVALUATION OF ATENOLOL SUCCINATE TRANSDERMAL PATCHES**

Nikhitha Mallampalli, Pisipati Aparna
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
nikhithamallampalli74@gmail.com

Use of TDDS provides a non-invasive method for drug delivery that enhances bioavailability, eliminates first-pass metabolism, and facilitates the release of controlled substances. Atenolol succinate, a cardio-selective beta-blocker, is frequently prescribed to manage hypertension and angina pectoris. The oral administration of drug results in low bioavailability (50%) due to first-pass metabolism and there by a short half-life, necessitating frequent dosing. By using a transdermal patch that contains atenolol, these limitations can be addressed by providing consistent drug delivery, better patient compliance, and reduced dosing frequency. In this work atenolol transdermal patches were prepared for long term use and controlled delivery. Objectives are, to manufacture transdermal patches of atenolol by using polymers, viz., HPMC, Eudragit as Penetrating enhancer, as plasticizer. The prepared patches were characterized for thickness, moisture content folding endurance and invitro drug release using Franz diffusion cell. The patches for evaluated for accelerated short term stability studies. The physicochemical parameters of prepared transdermal atenolol succinate patches, exhibited satisfactory properties and the invitro release was observed for 24hours. All the prepared patches demonstrated good stability, mechanical strength and drug release. These results showed a promising option for delivering atenolol in a sustained release form for an effective treatment for hypertension when compared to oral administration.

**Keywords**: Atenolol succinate, transdermal patch, TDDS, hypertension

**FORMULATION AND EVALUATION OF FLUVASTATIN FLOATING ORAL IN-SITU GEL**

Meghana, Ramya.K
Department of Pharmaceutics, Vikas Institute of Pharmaceutical Sciences, Nidagtla near airport, Rajahmundry, East Godavari district, Andhra Pradesh, India 533102
malemeghana414@gmail.com

The aim of the present study is to formulate and evaluate a floating oral in-situ gelling system of Fluvastatin to enhance gastric retention and achieve sustained drug release. In-situ gels are advantageous drug delivery systems that remain in solution form before administration and undergo sol-to-gel transition under physiological conditions, thereby improving bioavailability and patient compliance. In this study, Fluvastatin in-situ gels were prepared using polymers such as sodium alginate, guar gum, HPMC K4M, HPMC K15M, along with sodium citrate and calcium carbonate as cross-linking agents. Preformulation and drug-excipient compatibility studies confirmed no significant interactions, as evidenced by FT-IR analysis. Twelve formulations (F1–F12) were developed and evaluated for gelation capacity, floating lag time, total floating duration, viscosity, drug content, and in vitro dissolution. All formulations exhibited immediate gelation in acidic medium and satisfactory floating behavior. Among these, formulation F8 (containing guar gum) demonstrated optimum performance, with 98.08% drug release over 12 hours. The release kinetics followed zero-order ($R^2$ = 0.987) with Higuchi and super case II transport mechanisms. The study concludes that Fluvastatin floating oral in-situ gel is a promising system for achieving sustained gastric retention, improved bioavailability, and patient compliance.

**Keywords**: Fluvastatin, In-situ gel, Floating drug delivery, Sustained release, Gastroretentive system

**NANOPARTICLE-BASED DRUG DELIVERY SYSTEMS: ADVANCES, CHALLENGES, AND FUTURE PERSPECTIVES IN NANOMEDICINE: - A REVIEW ARTICLE**

Anannya Takalkhede, Amit Bhagat
Datta Meghe College of Pharmacy, Sawangi, Wardha, Maharashtra-442001
anannyatakalkhede@gmail.com

Nanoparticle drug delivery systems (NDDS) are breaking new ground for modern medicine as they combine the advantages of nanotechnology with materials science and pharmacology in order to achieve goals

ISBN: 978-81-980623-8-3

beyond traditional drug delivery methods. NDDS utilizes nanoscale carriers (liposomes, polymeric nanoparticles, dendrimers, metallic nanostructures, lipid-based) to enhance drug solubility, bioavailability, and site-specific delivery. NDDS is also active targeting based on ligand-receptor interactions - that result in reduced systemic toxicity and higher therapeutic effectiveness. NDDS could also integrate controlled and stimuli-responsive release, which would support extended therapeutic effects and improved patient compliance. It is not out of the realm of possibility to imagine multifunctional systems that simultaneously integrate diagnostic and therapeutic capabilities - otherwise known as theragnostic - that could monitor treatment outcomes in real-time. However, serious issues to be addressed looking ahead include scalability of production, long-term safety, regulatory approval, and biological barriers, such as the blood-brain barrier. Clinical formulations of NDDS (liposomal doxorubicin [Doxil®] and lipid nanoparticles used for mRNA vaccines) demonstrate both the feasibility of and the opportunity for systemic change in how drugs are delivered. Thus, NDDS offer new solutions for improved safety and efficacy in personalized therapy for a myriad of diseases and conditions that include oncology, infectious diseases, autoimmune diseases, and neurologic diseases.

**Keywords**: Nano Particle, bioavailability, nanostructure, stimuli responsive and oncology.

**PC-907**

**FORMULATION AND EVALUATION OF POLYVINYL ALCOHOL-BASED HERBAL ANTI-ACNE PAPER SOAP STRIPS**

Kadam Shreya Shankar
Swami Ramanand Teerth Marathwada University Nanded, Maharashtra 431606
shreyakadam577@gmail.com

Acne vulgaris arises from excess sebum production, follicular hyperkeratinization, and Propionibacterium acnes proliferation, leading to inflammation and lesions. Conventional treatments face limitations in portability and contamination. This study develops a polyvinyl alcohol (PVA)-based herbal anti-acne paper soap strip, incorporating neem leaf extract (antibacterial, anti-inflammatory), which extracted by aqueous maceration, green tea extract (antioxidant, sebum-regulating) extracted by hot water infusion, and tea tree oil (antimicrobial, anti-inflammatory) by steam distillation with Decyl Glucoside (mild cleansing, foam formation). Strips were cast, dried, and cut. pH, dissolution time, foam stability, and antimicrobial activity confirmed effectiveness, offering a portable, hygienic, and eco-friendly anti-acne dosage form.

**PC-908**

**FORMULATION AND EVALUATION OF BUCCO ADHESIVE ITRACONAZOLE TABLETS BY USING SOLID DISPERSION**

Vinta Katyayani, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108

In the present study mucoadhesive buccal tablet of Itraconazole was prepared. By enhance its solubility of Itraconazole was enhanced by complexing Itraconazole with β CD in 1:1 molar concentration. Six different formulations of tablets of Itraconazole containing the polymers and diluents in various combinations were prepared by direct compression method and characterized for swelling studies, surface pH, mucoadhesive properties and in-vitro release studies. All the formulations showed the satisfactory results bioadhesive performance, surface pH, physical & mechanical properties. The swelling index was proportional to content of HPMC K4M & carbopol as bioadhesive polymers. The surface pH of all tablets was found to be satisfactory, & close to neutral pH, hence, buccal cavity irritation should not occur with these tablets. Drug release and drug diffusion from the tablets were depended on the ratio of polymer and type of the diluent used in the formulation. Tablets containing Carbopol, HPMC K4M and spray dried lactose as diluent (F1 to F3) had the maximum percentage of in-vitro drug release than compared to tablets containing mannitol as diluents (F4 to F6). The formulation F1 can be considered as promising buccoadhesive tablets containing inclusion complex of Itraconazole with β-CD providing first order drug release over period of 8 hours.

**Keywords**: Mucoadhesion, Buccal tablets, In-vitro release and Sustained drug delivery.

**PREPARATION AND EVALUATION OF ATORVASTATIN CALCIUM MICROSPHERES BY EMULSION SOLVENT DIFFUSION METHOD**

Thota Kalyani, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
kalyanithota43@gmail.com

Atorvastatin, a selective competitive inhibitor of HMG CoA reductase, is effective in treating hyperlipidemia but faces challenges such as low solubility and limited bioavailability (14%).To address these issues, the researchers incorporated polymers Kolliphor P407, Gelucire 43/01, HPMCE15, and PVPK90 into the microsphere formulations. Sixteen formulations were prepared and evaluated for various parameters including flow properties, particle size, drug content, solubility, and in vitro drug release studies.Key findings of the study include-Microspheres prepared using the emulsion solvent diffusion technique significantly improved the solubility and dissolution rate of atorvastatin compared to the pure drug,Addition of polymers at 0.05% concentration further enhanced the dissolution rate, with Kolliphor P407 showing the highest impact, followed by Gelucire 43/01, HPMCE15, and PVPK90,Formulation ATR-F4 containing 0.05% Kolliphor P407 demonstrated the highest solubility (0.747 µg/ml) and dissolution rate (99.99% in 30 min) among all formulations tested.,Scanning Electron Microscopy (SEM) and Differential Scanning Calorimetry (DSC) analyses confirmed that the microspheres were porous, with a particle size of 26.75 µm, and showed no signs of chemical instability,Release kinetics analysis indicated that all formulations followed first-order kinetics.In conclusion, the study successfully optimized a formulation (ATR-F4) of atorvastatin microspheres using Kolliphor P407 to significantly enhance its solubility and dissolution rate, potentially improving its therapeutic efficacy for the treatment of hyperlipidemia.

**Keywords**: Atorvastatin, Kolliphor P407, Gelucire 43/01, HPMCE15 and PVPK90.

**FORMULATION, CHARACTERIZATION AND IN VITRO EVALUATION OF NOVEL IONICALLY CROSS-LINKED CASEIN NANOPARTICLES FOR MEMANTINE HYDROCHLORIDE DELIVERY**

Bandreddy Sravanthi Sai, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
sravanthisaibandreddy@gmail.com

The objective of the study was to fabricate protein nanoparticles for better controlled and targeting action of drug, which also overcome the problems associated with conventional formulations like multidose therapy, poor patient compliance and high cost. Memantine HCl loaded casein nanoparticles (F1 to F6) were prepared by Ionically crosslinked method. The formulated nanoparticles were evaluated for external morphological characters, determination of particle size analysis, zeta potential, drug content, entrapment efficiency and in-vitro release studies. The particle size varied from 148 to 317 nm and zeta potential was in negative and its value found to be - 46.4 mV. The drug content for the Memantine HCl loaded casein nanoparticles varied from 69.5 ± 7.2% to 87.9 ± 1.2%. The entrapment efficiencies were found to be minimum and maximum of 55.50 ± 2.4% and 86.30 ± 3.6%. The percentage yields of all formulations were in the range of 48.24 ± 1.24 to 86.13 ± 1.37%. In-vitro release of drug follows zero order and showed sustained release behaviour for a period of 24 hr. The optimized formulation contains 1:3 ratio of STTP & casein and demonstrated successful sustained release. Memantine HCl loaded casein nanoparticle is a potential new delivery system for treatment of Alzheimer's disease.

**Keywords**: Alzheimer's disease, Protein nanoparticles and ionically crosslinked method.

**DESIGN, PREPARATION, AND SOLID-STATE CHARACTERIZATION OF DACLATASVIR DIHYDROCHLORIDE POLYMORPHS FOR ENHANCED SOLUBILITY AND DISSOLUTION**

B. Sri Krishna Sravya, B. Poornima.

ISBN: 978-81-980623-8-3

Department of Pharmaceutical Analysis, Vijaya Institute of Pharmaceutical Sciences for Women (VIPW), Vijayawada.
srikrishnasravya07@gmail.com

Polymorphism plays a critical role in the development of active pharmaceutical ingredients (APIs), as different crystalline forms can significantly influence physicochemical properties, manufacturing performance, and therapeutic efficacy. Daclatasvir dihydrochloride, a direct-acting antiviral agent for the treatment of chronic hepatitis C virus (HCV) genotype 3 infection, belongs to the Biopharmaceutical Classification System (BCS) Class II, characterized by low aqueous solubility and high permeability. The present study aimed to develop and characterize novel polymorphic forms of Daclatasvir dihydrochloride to improve its solubility and dissolution profile. Various crystallization techniques, including solvent evaporation, binary solvent crystallization, anti-solvent addition, melt crystallization, and solvent-assisted grinding, were employed using different solvents and mixtures. The resulting solid forms were characterized by Fourier-transform infrared spectroscopy (FT-IR), differential scanning calorimetry (DSC), and powder X-ray diffraction (PXRD) to determine structural variations and thermal behaviour. Solubility and in vitro dissolution studies were conducted in phosphate buffer (pH 6.8). Distinct solid forms with reduced crystallinity were obtained, demonstrating significant differences in melting behaviour, diffraction patterns, and intermolecular interactions. Among the prepared forms, the ethanol–water binary solvent system (Solid Form D) exhibited the highest solubility (63.4 µg/mL) and improved dissolution (53.4% at 45 min) compared to the input material (59.06 µg/mL and 37.17% at 45 min). These findings underscore the potential of polymorphic manipulation to enhance the biopharmaceutical performance of poorly soluble antiviral agents. The study provides a foundation for selecting optimal solid forms of Daclatasvir dihydrochloride to achieve improved oral bioavailability and consistent therapeutic outcomes.

**Keywords**: Daclatasvir dihydrochloride, polymorphism, FT-IR, DSC, PXRD, solid-state characterization.

## DEVELOPMENT AND OPTIMIZATION OF SELF MICRO EMULSIFYING DRUG DELIVERY SYSTEM OF IRBESARTAN

Sk. Sabiha Taslim, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
sabihataslim04@gmail.com

The present study aimed to design, develop, and optimize a Self-Micro Emulsifying Drug Delivery System (SMEDDS) to enhance the solubility and dissolution profile of Irbesartan. SMEDDS are isotropic mixtures of oil, surfactant, and co-surfactant that spontaneously form fine oil-in-water microemulsions upon dilution in gastrointestinal fluids, thereby improving the dissolution and absorption of lipophilic drugs. Preformulation studies, including solubility testing and compatibility analysis by FTIR, confirmed the suitability of selected excipients. Pseudo-ternary phase diagrams were constructed to determine the emulsification regions and to optimize the ratios of oil (olive oil), surfactant (Tween 80), and co-surfactant (PEG 400). Various formulations (IF1–IF10) were prepared and evaluated for clarity, emulsification efficiency, and in vitro dissolution studies. Among them, formulation IF7 exhibited superior performance with rapid emulsification, stable microemulsion formation, and enhanced drug release kinetics best fitting a first-order model ($R^2 = 0.965$). Comparative studies demonstrated a significant increase in the dissolution rate of Irbesartan from optimized SMEDDS compared with pure drug. The findings highlight that SMEDDS provide a promising, simple, and industrially feasible approach to overcome solubility challenges, thereby improving oral bioavailability and therapeutic efficacy of poorly water-soluble drugs like Irbesartan.

**Keywords**: Irbesartan, SMEDDS, poorly water-soluble drugs, Oral bioavailability, Pseudo-ternary phase diagram and Drug release kinetics

## DEVELOPMENT AND OPTIMIZATION OF BENZOYL PEROXIDE LOADED ANISE OIL-BASED EMULGEL FOR EFFECTIVE MANAGEMENT OF ACNE VULGARIS USING BOX-BEHNKEN DESIGN.

1Sarthak Khamitkar, 2Sravanthi Bindla, 1Krishna Sanka
1Department of Pharmaceutics, School of Pharmacy and Technology Management (SPTM), SVKM's Narsee Monjee Institute of Management Studies (NMIMS), Deemed-to-University, Shirpur-425405, Maharashtra, India. 2School of Pharmacy, Anurag University, Ghatkesar, Hyderabad, TS-500088, India.
khamitkarsarthak@gmail.com

Emulgels are emerging as efficient delivery systems for hydrophobic drugs, combining emulsions' solubilization benefits with gels' controlled release properties. This study optimized a benzoyl peroxide-loaded emulgel for acne treatment using anise oil as the oil phase and Tween® 60/Span® 80 as emulsifiers. A Box-Behnken design evaluated the effects of Carbopol® 934P, Tween® 60, and Span® 80 on % drug permeation at 3 and 10 hours. The optimized formulation demonstrated 15.66% and 78.66% permeation, stable physicochemical properties, and superior antimicrobial efficacy over the marketed product. This patient-friendly emulgel presents a promising alternative for acne management.

**Keywords**: Acne vulgaris, Carbopol® 934P, Benzoyl peroxide, Emulgel.

**PC-914**

## FORMULATION AND EVALUATION OF MEBEVERINE HYDROCHLORIDE GASTRORETENTIVE FLOATING MICROSPHERES

D.Ramya, Sirisha Panda
Department of Pharmaceutical Sciences, Visakhapatnam, India -531162
Ramyadola004@gmail.com

Mebeverine hydrochloride (MGH) is an antispasmodic agent with a short gastric residence time and site-specific absorption, which limits its therapeutic efficacy. To overcome these drawbacks, gastroretentive floating microspheres were developed to prolong gastric retention and achieve sustained drug release. The microspheres were prepared by an oil-in-water (O/W) solvent evaporation and diffusion technique using polymer combinations such as Eudragit® RS/RL and ethylcellulose/hydroxypropyl methylcellulose (HPMC) blends. The resulting low-density, porous microspheres were evaluated for particle size distribution, surface morphology using scanning electron microscopy (SEM), production yield, entrapment efficiency (EE), in vitro buoyancy, swelling index, true density, and in vitro drug release behavior. Fourier-transform infrared spectroscopy (FTIR), differential scanning calorimetry (DSC), and X-ray diffraction (XRD) analyses were performed to assess possible drug–polymer interactions and confirm the stable incorporation of MGH. The prepared microspheres showed satisfactory yields with uniform spherical morphology. Entrapment efficiencies were high, ensuring adequate drug loading. Buoyancy studies revealed that the optimized formulations maintained more than 80% floating ability over 12 hours. The drug release studies demonstrated sustained release of MGH for up to 12 hours, following Higuchi and Korsmeyer–Peppas kinetics, indicating diffusion-controlled release with anomalous transport. Stability testing under accelerated conditions confirmed good physicochemical stability of the optimized formulations. Overall, the developed floating microspheres of MGH successfully prolonged gastric retention, improved buoyancy, and provided controlled release, offering a promising approach for enhancing therapeutic efficacy in the management of gastrointestinal spasms.

**Keywords**: mebeverine, floating microspheres, gastroretentive, Eudragit.

## FORMULATION AND EVALUATION OF PRONIOSOMAL GEL FOR TOPICAL DELIVERY OF ORNIDAZOLE

Sk. Sharmila, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
sharmilashaik444@gmail.com

Acne vulgaris is a common inflammatory skin disorder. It affects the pilosebaceous units followed by an overgrowth by Propionibacterium acne bacteria. The current work aims to develop a topical proniosomal carrier system for ornidazole to manage acne vulgaris which is capable of efficiently delivering entrapped drug over an extended period. The desired ornidazole loaded proniosomal gel was formulated by employing a slurry technique using cholesterol, Span 60, and carbopol 934. The

ISBN: 978-81-980623-8-3

formulated proniosomal gels were characterized by FTIR, drug loading, entrapment efficiency, surface morphology, particle size, zeta potential, pH, and viscosity. Further, evaluated for in vitro drug release, ex vivo permeation, and stability profile. The optimized proniosome F5 suggested that particles were spherical and near homogeneous with relatively smoother surfaces with a particle size of 20 nm. The optimized formulation F5 had shown a drug loading of 25.83% and an entrapment efficiency of 97.66%. Further, the optimized proniosomal gel G2 had shown enhanced permeation (91.12 % in 12h) and displayed sustained release when compared with plain gel (74.29 % to 78.33% over 12h). Stability studies suggested that formulated proniosomal gel was highly stable at 4-8°C. In conclusion, the formulated ornidazole loaded proniosomal gel can be used as a potential therapeutic alternative for managing acne vulgaris.

**Keywords**: Ornidazole; Acne vulgaris; Proniosome; Gel; Sustained drug delivery; Slurry technique

**MULTI-STAGE COMPUTATIONAL EVALUATION TO EXPLORE THE ANTI-TUBERCULAR POTENTIAL OF BEDAQUILINE PYRIDYL DERIVATIVES**

Anguraj Moulishankar2, T.Sundarrajan1
1 Department of Pharmaceutical Chemistry, SRM College of Pharmacy, SRM Institute of Science and Technology, Kattankulathur, Chengalpattu-603203, Tamil Nadu, India
2 Integrated Drug Discovery Centre, Department of Pharmaceutical Chemistry, Acharya & BM Reddy College of Pharmacy, Bengaluru, Karnataka, India

Tuberculosis is a major global health issue, worsened by rising drug resistance. ATP synthase, crucial for energy production, is a promising target for anti-tubercular drugs. Bedaquiline, an ATP synthase inhibitor, is effective but has limitations like high lipophilicity. This study explores Bedaquiline pyridyl derivatives using QSAR modeling, molecular docking, and ADMET analysis to develop better treatments. The study utilized QSARINS software for 2D QSAR modeling and descriptor selection, with molecular descriptors calculated using PaDEL and ChemDes. A dataset of 60 bedaquiline pyridyl derivatives with MIC90 values was split (75:25) for training and testing. Molecular docking of ligands with M. tuberculosis ATP synthase (PDB ID: 4V1H) was performed using AutoDock, followed by MD simulations with GROMACS. ADMET properties were analyzed using SWISSADME and pkCSM tools to evaluate pharmacokinetics, toxicity, and drug-likeness. This study developed and validated four QSAR models for predicting ATP synthase inhibition in Mycobacterium tuberculosis, with Model 4 showing optimal statistical performance ($R^2$ = 0.8518, $Q^2LOO$ = 0.8025). Using Model 4, novel bedaquiline derivatives were designed, exhibiting enhanced predicted pMIC90 values compared to the reference drug. Molecular docking revealed BP-2d as the top-performing compound (-8.1 kcal/mol), surpassing Bedaquiline (-6.6 kcal/mol) with key binding interactions. Molecular dynamics simulations confirmed the stability and binding consistency of BP-1d and BP-2d with ATP synthase. The QSAR analysis identified Model 4 as the most reliable for predicting the anti-tubercular activity of bedaquiline-pyridyl derivatives, with robust statistical validation ($R^2$ = 0.8518, $Q^2LOO$ = 0.8025). Key molecular descriptors influencing ATP synthase inhibition were highlighted, enabling the design of novel derivatives. Among the designed compounds, BP-1d (pMIC90 = 7.8810) and BP-2d (docking score = -8.1 kcal/mol) emerged as potent candidates. Computational studies underscore their potential as promising lead compounds for further experimental validation against Mycobacterium tuberculosis.

**Keywords**: QSAR, Bedaquiline Pyridyl derivative, Molecular docking, Molecular Dynamics, Anti-tubercular activity

**PROLIPOSOME BASED TRANSDERMAL DELIVERY OF SIMVASTATIN**

Ramshetti Rajendra Prasad1 , Uppu Pavani2
1Vaagdevi Pharmacy College, Bollikunta, Warangal, Telangana, India.
2Nethaji Institute of Pharmaceutical Sciences, Kazipet,Hanamkonda, Telangana, India.

Simvastatin is classified as a BCS–II drug and experiences considerable first-pass metabolism, which leads to low oral bioavailability in humans (5-8%). The objective of the present research was to develop and evaluate Simvastatin Proliposomes for Transdermal Delivery. Proliposomes were prepared to improve bioavailability & they were prepared by Coacervation-Phase seperation method using Cholestrol and Lecithin were used in different ratios. Average globule size and Poly Dispersity Index (PDI) were found to be in between 285.2 ± 2.8 to 452.3 ± 1.8 nm and 0.21 ± 0.03 to 0.32 ± 0.04 respectively. Zeta potential values varied from −22.0 ± 0.15 to −30.9 ± 0.20 mV. All formulations showed good entrapment efficiency ranging from 81.52 ± 1.3 to 92.35 ± 2.4%. In-vitro studies, F3 formulation showed better release (94±2.8%). Effect of Charge inducers like Stearyl amine & Sodium cholate were studied. In-vitro release kinetics follows zero order with higuchi model. Histopathological study reveals that, the surface epithelium lining and the granular cellular structure of the skin was disturbed, it indicates vesicle deposition in skin. DSC studies indicated that there are no drug-excipient interactions. From the results, it was concluded that the proliposomal gels offer good controlled delivery of Simvastatin which improves the bioavailability.

**Keywords**: Proliposomes, Bioavailability & Transdermal delivery.

AIMS College of Pharmacy, AIMS Foundation, Vadavali, Dombivali (E)

The use of more than one herb in a therapeutic preparation is known as polyherbal formulation. The idea comes from Ayurveda and other traditional therapeutic systems, which use various herbs in a specific ratio. Skin serums are light cosmetics with a high active ingredient concentration. Antiaging Serum is one of several different forms of oil and water-based serums that have varied actions. Antiaging serums are primarily concerned with minimising the signs and symptoms of ageing; they are known to absorb swiftly into the skin, delivering an intensive dose of chemicals and preventing fine lines, wrinkles, inflammation, and dark spots. Our formulation consists extracts of Camellia sinensis (Green tea) and Psidium guajava (Guava Leaves) which are known to possess antioxidant properties. The antioxidant action of guava and Tea polyphenols makes them Polyherbal formulation refers to the use of many herbs in a medicinal preparation. The prime ingredient to be used in Antiaging Formulations. Apart from these Aloe vera, Glycerine, Lavender Oil and Honey are used as excipients which enhances the action of active ingredients.

**Keywords:** Anti-ointment, Ointment mask, Guava leaf, Green Tea.

dilpreet.daman@gmail.com

This review critically evaluates the emerging role of lactoferrin, an iron-chelating glycoprotein, as a macromolecular ligand in precision cancer therapy. Lactoferrin exhibits potent anti-tumour, anti-inflammatory, and immunomodulatory properties and targets cancer cells via high-affinity binding to transferrin and LDLreceptor-related proteins, enhancing selectivity and minimizing off-target toxicity. It modulates key oncogenic pathways such as PI3K/Akt and MAPK to suppress tumour growth and metastasis. Nanoformulations—like liposomes and polymeric nanoparticles—improve pharmacokinetics, enable targeted drug delivery, and enhance therapeutic efficacy. Lactoferrin's ability to cross biological barriers, including the blood-brain barrier via receptor-mediated transcytosis, offers promise for treating difficult cancers such as glioblastoma. Additionally, it enhances anti-tumour immunity by

ISBN: 978-81-980623-8-3

activating NK cells and polarizing macrophages to the M1 phenotype. Importantly, lactoferrin helps overcome multidrug resistance by modulating efflux pumps like P-glycoprotein. Integrating molecular insights with preclinical and clinical evidence, this review underscores lactoferrin's transformative potential in precision oncology through advanced nanoformulations and synergistic immunomodulatory mechanisms.

**LULICONAZOLE - NATURAL DEEP EUTECTIC SOLVENTS PREPARATIONS: SOLUBILITY ENHANCEMENT FORMULATION AND BIOLOGICAL ACTIVITY EVALUATION.**

Dipak D Patil, Nilesh Kukde, S B Bari, Kishore S Salunkhe
Department of Pharmaceutical Chemistry, K K Wagh College of Pharmacy, Nashik – 422 003. Maharashtra, India.

Luliconazole (LCZ) a topical antifungal agent shows poor water solubility and skin permeability. The LCZ solubility was enhanced through the synthesis of Natural Deep Eutectic Solvent (NDES) preparation. The LCZ-NDES was formulated and evaluated. A total of 24 various NDES preparations consisting of choline chloride in combination with Malonic acid, Propylene glycol, glycerol, D - Sorbitol, Glucose, Sucrose, Fructose and urea were synthesized with different molar ratios. The preparations were characterized using FT-IR, DSC, Motic digital microscopy, and proton nuclear magnetic resonance and evaluated for solubility enhancement and in vitro drug release. The gel was evaluated for pH, viscosity, spreadability, texture analysis, in-vitro drug release and antifungal activity. From the synthesized NDES, the ChCl: MA combination showed the optimum solubility of LCZ with optimized pH. The solubility enhancement ratio of LCZ was about more than 150 using optimized NDES as compared to water. The crystalline transition of LCZ in NDES was confirmed through characterization studies. The NDES-LCZ gel has better texture properties like hardness, adhesiveness, cohesiveness, gumminess and viscosity and spreadability as compared to a pure drug containing LCZ gel. The % cumulative LCZ release value was higher in the case of NDES-LCZ as compared to LCZ gel. The comparatively higher antifungal activity of NDES-LCZ gel was observed. Thus, the findings of the study demonstrate NDES containing LCZ gel with improved solubility and antifungal activity.

**Keywords**: Luliconazole, Natural Deep Eutectic Solvent, solubility enhancement, choline chloride, antifungal activity.

**PC-921**

**FORMULATION, CHARACTERIZATION AND OPTIMIZATION OF VENLAFAXINE- QUETIAPINE NANOPARTICLES FOR INTRANASAL ADMINISTRATION IN TREATMENT RESISTANT DEPRESSION**

Kiran A. Tengse, Jayshree B.Taksande
Department of Pharmaceutics, Smt. Kishoritai Bhoyar College of Pharmacy Kamptee Dist. Nagpur, Maharashtra, India - 441 002
tengsekiran@gmail.com

In the present work, chitosan nanoparticles of venlafaxine (VNLFX) and quetiapine (QTP) were formulated and characterized. The objectives of the present study were to check the physicochemical compatibility among the APIs and Excipients, to formulate, evaluate and optimize venlafaxine- quetiapine chitosan nanoparticles, to perform the in-vitro and ex-vivo study. The nanoparticles were prepared by ionic gelation technique using Box-Behnken Design (BBB). The FTIR & DSC study confirmed compatibility of components for nanoparticles formulation. The prepared nanoparticles were characterized for particle size, zeta potential, polydispersity index (PDI) and % entrapment efficiency. The optimized batch with chitosan concentration 0.5% w/v, cross linker sodium tripolyphosphate 0.2% w/v and homogenization time 5 minutes shown particle size of 115.6 nm, zeta potential 51.6 mV, PDI 0.42 and % entrapment efficiency for VNLFX 86.2% and for QTP 76.3% out of all 15 formulation batches. SEM images of the optimized formulation was found roughly spherical and sub spherical in shape. In-vitro drug release from optimized formulation for both drugs shown initial burst release followed by characteristic sustained release for more than 24 hrs. Ex-vivo permeation study on goat nasal mucosa for 12 hours showed VNLFX 35.3% and QTP 26.2% release. Thus, it can be concluded that this study may be beneficial for the formulation of VNLFX-QTP nanoparticles for intranasal administration in Treatment Resistant Depression.

**Keywords**: chitosan nanoparticles, Box-Behnken Design, ionic gelation technique, intranasal, Treatment Resistant Depression.

**SMART DRUG DELIVERY SYSTEM: ADVANCING PRECISION, SAFETY AND PATIENT-CENTERED THERAPEUTIC**

D.Sarina, B.Sravanthi, D.Greeshma, G.Ramakrishna
Bhaskara Institute of Pharmacy, Komatipalli Village Bobbili Affiliated By Andhra University India -535558
Dunnasarina0@Gmail.Com

Smart drug delivery systems (SDDS) are an innovative class of therapeutic platforms designed to enhance the safety, efficacy, and patient convenience of pharmacological treatments. Unlike conventional dosage forms, which often release drugs non-selectively, SDDS employ advanced carriers and stimuli-responsive mechanisms to deliver therapeutic agents at the right site, rate, and time. Materials such as nanoparticles, liposomes, dendrimers, polymeric micelles, hydrogels, and implantable reservoirs can encapsulate or conjugate drugs, protecting them from premature degradation and improving bioavailability. A defining feature of SDDS is their ability to respond to internal or external cues—such as pH, temperature, enzymes, redox potential, ultrasound, magnetic fields, or light—to modulate drug release. This "on-demand" functionality enables precise dosing and reduces systemic toxicity, particularly in challenging conditions like cancer, infections, or inflammatory diseases. Integration with microelectronics and biosensors has also given rise to "intelligent" devices, including smart pills and wearable or implantable pumps, which can monitor patient parameters and adjust therapy in real time. Applications of SDDS span oncology, diabetes management, neurological disorders, and gene or protein delivery, supporting the shift toward personalized medicine. Additionally, sustainable manufacturing and biodegradable excipients are being explored to improve the environmental footprint of these technologies. By combining controlled release, site specificity, and patient-centric design, smart drug delivery systems offer a transformative pathway to optimize therapeutic outcomes and minimize adverse effects. Continued interdisciplinary research in materials science, biomedical engineering, and pharmacology is expected to accelerate

**Keywords**: Smart drug delivery system, nanoparticles, liposomes, hydrogels, targeted therapy.

**DEVELOPMENT AND EVALUATION OF EVEROLIMUS LOADED SOLID LIPID NANOPARTICLES GEL FOR THE TREATMENT OF ATOPIC DERMATITIS**

Abirami K, Katikala Tanvi, M P Venkatesh
Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, Mysuru, KA, India.
abikirann@gmail.com

The present work reports the successful formulation and assessment of Everolimus-loaded solid lipid nanoparticles (SLNs) embedded in a topical gel, designed for targeted management of atopic dermatitis. SLNs were prepared via hot homogenization followed by solvent evaporation, utilizing stearic acid as the lipid base and Poloxamer 188 as the surfactant. The resulting gel formulations exhibited a uniform, smooth, white appearance and maintained pH values within the optimal topical range (5.0–7.0), ensuring skin compatibility and minimizing irritation risk Rheological characterization demonstrated appropriate viscosity and spreadability, supporting effective application and skin retention. Particle size analyses indicated nanoscale SLNs ranging from 601 to 832 nm with polydispersity indices between 0.341 and 0.392, confirming relatively uniform size distribution. The optimized formulation (F3) achieved a mean particle size of 633 nm and PDI of 0.398, suitable for enhanced dermal penetration. Homogenization at 10,000 rpm for 5 minutes effectively reduced particle size and improved formulation stability. The Everolimus-loaded SLN gel showed favorable physicochemical properties, indicating promise as a topical delivery system for localized therapy in atopic dermatitis. This strategy may improve local therapeutic outcomes and minimize systemic adverse effects compared to conventional oral Everolimus administration.

Colorectal cancer (CRC) is a frequently occurring malignant disease that affects people worldwide, especially those who are 50 years old or older and have a higher chance of developing the disease. Although improvements in diagnostic techniques and early screening have led to a decrease in cancer-related deaths, there remains an urgent want for novel treatment approaches. Scientists are quickly acknowledging the importance of nanoparticles (NPs) in improving the accuracy, effectiveness, and availability of diagnostic and treatments by enhancing the precision, solubility, and accessibility of pharmaceuticals. Nanoparticles (NPs) show potential in reducing medication toxicity and specifically targeting malignant tumors, therefore decreasing adverse side effects. This study comprehensively evaluates the practicality of using various nano products to detect and treat colorectal cancer (CRC). This study adds to the paradigm change in CRC management by conducting a thorough analysis of the potential of NPs. Incorporating cutting-edge nanotechnologies into CRC treatments can bring about significant changes, providing a way to develop individualized and precise therapies. This analysis highlights the need to use new and creative methods to satisfy the ongoing requirement for advanced therapies in light of the worldwide effect of colorectal cancer (CRC). With the increasing need for effective treatments, investigating nanoproducts becomes a new area of study with significant implications for CRC management. This highlights the need for ongoing research and development in this rapidly evolving sector

## Niosomal Gel of Capsaicin: A Novel Sustained-Release Topical Approach for Rheumatoid Arthritis

Elahe Tolideh, Preeti Karwa, Ayesha Syed
Department of Pharmaceutics, Al-Ameen College of Pharmacy, Bengaluru
elahetolideh2233@gmail.com

Rheumatoid arthritis (RA) is a chronic inflammatory disorder characterized by persistent joint pain and swelling, where conventional systemic therapies often lead to adverse effects and poor patient compliance. To address this, the present study was designed to develop a novel niosomal-based topical gel of Capsaicin, a natural analgesic agent, for sustained and localized delivery in arthritis management. Capsaicin-loaded niosomes were prepared by ether injection and thin film hydration methods and optimized using a $3^2$ factorial design, considering cholesterol concentration (A) and surfactant concentration (B) as critical variables, while particle size, entrapment efficiency, and PDI served as responses. Optimized formulations demonstrated particle sizes of 640.1 nm and 728.8 nm, with entrapment efficiencies of 95.2% and 86%, and favorable PDI values (0.010 and 0.394). In-vitro release studies revealed sustained profiles with 81.27% and 98.21% release, respectively. The optimized gel, prepared by incorporating optimized niosomal dispersion into carbopol 934, exhibited ideal topical properties with pH 6.74 ± 0.04, excellent homogeneity, spreadability, and viscosity. Comparative diffusion studies confirmed that the niosomal gel (31.78%) and niosomal dispersion (40.77%) provided markedly sustained release over 8 h compared with plain drug gel (63.21%) and drug solution (85.86%). Furthermore, skin irritation testing confirmed the formulation's safety and tolerability. Overall, the study demonstrates that niosomal gel offers a promising carrier system for localized, sustained, and irritation-free delivery of Capsaicin, potentially improving therapeutic outcomes and patient adherence in arthritis therapy.

## PREPARATION OF ETRAVERINE NANOSUSPENSION WITH DIFFERENT PROPORTION OF POLYMER'S AND IT'S EVALUATION

Radhika Parasuram Rajam, Merlin Ilango, Giriprasath Shanmugam
Department Of Pharmaceutics, The Erode College Of Pharmacy Erode-638112, Tamilnadu, India
Merlinilango11@Gmail.Com

The objective of this study was to design, develop, optimize, and evaluate chitosan-based Etravirine nanosuspension to enhance solubility and drug release.Etravirine nanosuspension was prepared using a modified solvent evaporation and ionic cross-linking method, followed by optimization through a Box-Behnken design. The influence of drug, chitosan, and sodium tripolyphosphate concentrations on particle size, entrapment efficiency, and drug release was assessed. Optimized formulations were characterized using Zetasizer, transmission electron microscopy, X-ray diffraction, and saturation solubility studies. A three-level, three-factor response surface design was employed to generate regression equations for predicting responses and identifying the optimal design space. Among the prepared formulations, batch F6 demonstrated superior characteristics: particle size of 225 nm, polydispersity index of 0.2, zeta potential of +30 mV, drug release of 94%, and entrapment efficiency of 80%. The saturation solubility of batch F6 (94.6±3.1%µg/ml) was markedly improved, showing a 22-fold enhancement compared to pure crystalline Etravirine (4.02 ± 0.03 µg/ml).Etravirine, an antiretroviral drug with poor oral bioavailability due to lipophilicity, crystallinity, low permeability, and first-pass metabolism, was successfully incorporated into a chitosan-based nanosuspension. The optimized formulation significantly improved solubility and drug release, suggesting its potential to enhance absorption and bioavailability. This nanosuspension approach offers a promising strategy to overcome biopharmaceutical limitations of Etravirine and improve its therapeutic efficacy in oral administration.

**Keywords**: Etravirine, Nanosuspension, Box Behnken method, Nanoparticles

## DESIGNING THE DENDRIMER-BASED DRUG DELIVER FOR ANTINEOPLASTIC THERAPIES

Tanya Patel1,2, Mohammad Adnan Raza1, Anjila Firdous1, Umesh Gupta2, Umesh Patil3, Ambika Singh1, Ajazuddin1,4
Department of Pharmaceutics, Rungta College of Pharmaceutical Sciences and Research, Bhilai, Chhattisgarh 490024, India
Nano-polymeric Drug Delivery Lab, Department of Pharmacy, School of Chemical Sciences and Pharmacy, Central University of Rajasthan
pateltanya336@gmail.com

Dendrimers, a sophisticated nanoscale concept, are transforming cancer treatment by tackling the critical challenges plaguing conventional therapies: poor drug solubility, systemic toxicity, oral bioavailability, side effects, and drug resistance therapy. These branched molecular frameworks serve as attractive drug delivery nanocarriers, with their engineered structure enabling controlled release and targeted delivery of chemotherapeutic agents. This breakthrough promises to enhance the therapeutic index of anticancer drugs dramatically. We explore how these systems optimize crucial parameters, such as release kinetics,hydrophobic drug encapsulation, reduced toxicity, and mimic protein. Engineering these molecular carriers necessitates careful consideration ofsurface chemistry and the role of the functional group, with each feature being carefully tweaked to maximize therapeutic effectiveness. The field has observed amazing advances through the application of innovative polymeric studies, particularly poly(amidoamine),poly[lactic-co-glycolic acid], and PEGylated dendrimers. These sophisticated designs have proven exceptional promise in enhancing biocompatibility and achieving accurate drug targeting at the site of action. Our research expands on the phenomenal versatility of dendrimer-based delivery systems across a wide range of new delivery strategies, including targeted delivery, gene therapy, photodynamic therapy, and photothermal treatment as well as immune response enhancement and stimuli-responsiveness. Preclinical and clinical research has provided persuasive evidence that they can reduce

ISBN: 978-81-980623-8-3

off-target toxicity while increasing therapeutic outcomes. Considering these hopeful advancements, significant barriers remain on the way to widespread clinical acceptance. These include complex safety assessments for long-term usage and meeting regulatory standards for FDA approval. As we look ahead, the continued development of multifunctional dendrimers holds remarkable promise for altering cancer therapy; however, additional clinical validation will be required to realize their full potential in medical practice.

**FORMULATION AND EVALUATION OF HERBAL MICRO BEADS LOADED WITH HESPERETIN AND CURCUMIN FOR ANTI-CANCER ACTIVITY**

Radhika Parasuram Rajam, Elavarasan S.R, Giriprasath Shanmugam
Department Of Pharmaceutics, The Erode College of Pharmacy, Erode, Tamilnadu, India.
Elavarasanvimala03@Gmail.Com

Cancer remains the second leading cause of death worldwide, with chemotherapy being the most commonly employed treatment. However, natural products and their derivatives have gained attention as alternative therapeutic agents due to their broad biological activities and relatively low toxicity. The present study investigated the anti-proliferative activity of hesperetin and curcumin in combination therapy, delivered in the form of microbeads, and their effects on cell viability in HeLa cell lines. Microbeads were prepared using a cross-linking method, and the anticancer effects of the formulations (A1, A2, A3) were evaluated using the MTT (3-[4, 5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) assay. Cytotoxicity was quantitatively assessed spectrophotometrically by measuring the formazan product formed via mitochondrial dehydrogenases, which correlates with viable cell count. Among the tested formulations, A3 (2% sodium alginate, hesperetin + curcumin) exhibited the highest swelling index (618.05 ± 5.15) and encapsulation efficiency (56.08%). A3 also demonstrated superior cytotoxicity, with an $IC_{50}$ value of 41.88 µg, which was lower than the $IC_{50}$ values observed for hesperetin and curcumin individually. These findings suggest that the combination of hesperetin and curcumin, delivered through microbeads, may serve as a promising anticancer strategy against HeLa cell lines. Further in vivo research and clinical studies are required to validate these results and establish the efficacy and safety of this approach in human patients.

**3D PRINTING: THE NEXT FRONTIER IN PERSONALIZED MEDICINE**

Ladi Alik Kumar1, Gurudutta Pattnaik1, Naga Jogayya Kothakotaa, Nilima Shukla3, Chandan Mohanty4, Dibyalochan Mohanty5, Sucharita Babu1
1Centurion University of Technology and Management, Odisha
2 Centurion University of Technology and Management, Andhra Pradesh
3 Sri Jayadev College of Pharmaceutical Sciences, Bhubaneswar, Odisha, India
4 Department of Pharmacy, Guru Nanak Institutions Technical campus, Hyderabad
5 School of Pharmacy, Anurag University, Hyderabad, India.

Applications for 3D printing in the development and targeting of solid, semi-solid, and locally delivered or implanted pharmaceuticals are numerous. This technology enables the incorporation of one or more drugs into a single solid dosage form, offering benefits such as enhanced patient compliance, improved ease of swallowing, customized release profiles, and the creation of novel medications for which no existing dosage forms are available. Long term release Joint replacement treatments, medical prostheses, and cardiovascular applications have been the main uses for 3D-printed implants, stents, and medical equipment. Additionally, 3D printing has been employed to produce locally applied medications, including medicated contact lenses, microneedles, and wound dressings. However, selecting the most suitable 3D printing technique for each application and developing pharmaceutical inks with the required physicochemical and biological properties remain significant challenges. The integration of 3D printing, with nanotechnology based biopharmaceuticals and therapeutics positions customized printed nanomedicines as a key innovation for the future. Continuous fabrication using 3D-printed microfluidic chips further facilitates their adoption in clinical practice.

**IN-VITRO EVALUATION OF FEXOFENADINE HYDROCHLORIDE TABLETS: A BIOEQUIVALENCE STUDY ACROSS DIFFERENT BRANDS**

M.Saritha, N.Malyadri Lakshmi Narasimha, Saritha Medapati, Srinivasa Rao Yarraguntla
Department of Pharmaceutics, Vignan Institute of Pharmaceutical Technology, Duvvada, Beside VSEZ, Visakhapatnam, Andhra Pradesh-530049, India.
chsaritha1975@gmail.com

Fexofenadine Hydrochloride is a second generation oral antihistamine indicated to relieve signs and symptoms of related to seasonal allergic rhinitis in children. The aim of the present study is to establish the pharmaceutical equivalence of different brands of Fexofenadine Hydrochloride 120 mg tablets available in the market. The quality control tests performed are weight variation, friability, hardness, disintegration and invitro dissolution studies. In-Vitro dissolution studies of Fexofenadine Hydrochloride 120 mg tablets were carried out in 6.8 pH phosphate buffer. Two samples are compared with the Innovator product. During the evaluation no major difference was noticed in weight variation, friability, hardness, disintegration and in dissolution between the two market products and the innovator product.

**Keywords**: Fexofenadine Hydrochloride, weight variation, friability & invitro dissolution studies

**DESIGN, DEVELOPMENT AND CHARACTERIZATION OF GRISEOFULVIN LOADED NLC TABLETS**

Sachin B. Gholve1, Shivappa N. Nagoba2, Rachita B. Malshette2, Dinesh V. Kamble1, Datta G. Survase1
1Dr. Narayanrao Chate College of Pharmacy, Chapoli, Dist. Latur Maharashtra.
2Department of Pharmaceutics, Channabasweshwar Pharmacy College (Degree), Latur.

To design, development and characterization of a nanostructured lipid carrier (NLC)-loaded tablet containing griseofulvin to enhance its oral bioavailability and stability for the effective antifungal. The primary objective of this study is to overcome limitations of conventional fungal therapies by formulating optimized NLCs and incorporating them into oral tablets and evaluated. Griseofulvin -loaded NLCs were prepared by high-speed homogenization using varying ratios of solid and liquid lipids with surfactants. The resulting NLCs were characterized; optimized NLCs were compressed into tablets and evaluated. FTIR and DSC confirmed no drug–excipient incompatibility and verified griseofulvin melting point. In vitro studies showed controlled and enhanced drug release. The optimized NLC (CF4) had a particle size of 178.5 nm, high drug content (94.56%), and excellent entrapment efficiency (96.20%). SEM, TEM confirmed smooth, spherical particles. Stability studies indicated good formulation stability. griseofulvin -loaded tablets were prepared by direct compression. Pre- and post-compression evaluations met standard ranges, with batch F7 showing optimal results: drug content (95.75%), drug release (96.86%), and stability study shows good formulation stability. The findings indicate that griseofulvin-loaded NLCs tablet offer a promising strategy for effective and controlled delivery of antifungal agents.

**Keywords**: griseofulvin, NLC, Tablets Antifungal, NDDS etc.

ISBN: 978-81-980623-8-3

Oral administration of antihypertensive drugs like Metoprolol Succinate is often limited by low bioavailability due to first-pass metabolism and the need for frequent dosing, which reduces patient compliance. Transdermal drug delivery systems (TDDS) offer a promising alternative by enabling controlled drug release, enhanced bioavailability, and improved therapeutic efficacy. This study focused on the formulation and evaluation of Metoprolol Succinate transdermal patches for the treatment of cardiovascular disorders. The patches were developed using solvent casting technique with synthetic polymers such as Hydroxypropyl Methylcellulose (HPMC K4M) and Polyvinylpyrrolidone (PVP K30). Dibutyl phthalate was used as a plasticizer and Dimethyl Sulfoxide (DMSO) as a penetration enhancer. The prepared patches were evaluated for various physical and chemical parameters including thickness, drug content, moisture content, and in-vitro drug release. Among all formulations, MP5 demonstrated most consistent and extended drug release over 24 hours, following zero-order kinetics and a non-Fickian diffusion mechanism. FT-IR spectroscopy confirmed the absence of drug-excipient interactions, supporting the chemical stability of the formulation. The in-vitro studies were validated, while stability studies under accelerated conditions indicated the durability and shelf-life of the patches. Overall, the developed transdermal patches of Metoprolol Succinate are suitable for once-daily administration, and further studies can be carried out for extending the release for few more days and can be viable alternative to oral therapy.

**Keywords**: Beta-1 adrenergic blocker Metoprolol Succinate, non-Fickian diffusion.

**PC-933**

## FORMULATION AND ENHANCED DRUG DELIVERY OF DICLOFENAC SODIUM TRANSDERMAL PATCHES USING POLYMER BLENDS OF ETHYL CELLULOSE, GUAR GUM, HPMC, AND PVP: COMPARATIVE DRUG RELEASE STUDY

Veena R S, Rashmi P, Harshita Nehru, Hoor-ul-Aeen
Department of Pharmaceutical Sciences, MVM College of Pharmacy, Bangalore-560064
veenars942@gmail.com

Diclofenac sodium transdermal patches were successfully developed using polymer blends such as Guar gum/PVP, HPMC/PVA, and EC/HPMC, all demonstrating excellent film-forming ability. The prepared patches were thin, flexible, smooth, and transparent, with minimal weight variation, indicating uniform distribution of drug and polymers. Patch thickness increased with higher concentrations of hydrophilic polymers, including PVP, PVA, and HPMC, which also enhanced flexibility and folding endurance. Moisture content was generally low but slightly elevated in hydrophilic formulations. In-vitro drug release studies revealed that patches with larger quantities of hydrophilic polymers (F1–F5) exhibited faster drug release, whereas patches with higher hydrophobic polymer content (F6 and F7) provided sustained release. Permeability measurements confirmed the desired flux and controlled release profile for F6 and F7 formulations. The solvent casting technique proved effective for fabricating transdermal patches with uniform characteristics, mechanical stability, and reproducible drug release. Overall, the results indicate that careful selection and combination of hydrophilic and hydrophobic polymers can modulate drug release kinetics, improve flexibility, and enhance patch stability. Diclofenac transdermal patches developed in this study have the potential to increase bioavailability, reduce dosing frequency, and provide better control of drugs with short half-lives or narrow therapeutic indices, making them suitable for patient-compliant, long-term therapy. The study highlights the importance of polymer composition in optimizing physicochemical properties and in-vitro performance of transdermal drug delivery systems.

**Keywords**: Guargum, Hydrophobic Polymers, Transdermal patches, In-vitro drug release.

## IMEGLIMIN-LOADED POLYMERIC NANOPARTICLES FOR SUSTAINED DRUG DELIVERY: A NOVEL APPROACH TO TYPE 2 DIABETES MANAGEMENT

P K Devibala, Balagaani Pavan Kumar, CH. Pooja
Department of Pharmaceutics, Gokula Krishna College of Pharmacy, Sullurupeta, Andhra Pradesh, India-524121.

Imeglimin, a novel oral antidiabetic agent that targets mitochondrial bioenergetics and improves insulin sensitivity, faces low oral bioavailability, which restrict its therapeutic potential. The present study aimed to develop and evaluate polymeric nanoparticles of Imeglimin to enhance its oral bioavailability. Polymeric nanoparticles were prepared using the solvent evaporation method, employing biodegradable polymers such as poly(lactic-co-glycolic acid) (PLGA) and stabilizers like polyvinyl alcohol (PVA). The formulations were optimized based on particle size, polydispersity index (PDI), zeta potential, entrapment efficiency, and in vitro drug release profiles. The optimized nanoparticles exhibited a mean particle size in the nanometric range (<200 nm), a narrow PDI indicating uniformity, and high drug entrapment efficiency (>80%). In vitro release studies demonstrated a sustained drug release over 24 h, suggesting potential for prolonged therapeutic action. Morphological evaluation by scanning electron microscopy confirmed spherical and smooth nanoparticles. Furthermore, in vivo pharmacokinetic studies in Wistar rats revealed significantly improved oral bioavailability of Imeglimin nanoparticles compared to pure drug suspension. These findings highlight the potential of polymeric nanoparticle-based delivery of Imeglimin as a promising approach to overcome bioavailability challenges, thereby enhancing its therapeutic efficacy in the management of type 2 diabetes mellitus.

**Keywords**: Imeglimin, polymeric nanoparticles, oral bioavailability, sustained release, antidiabetic activity

## NEXT-GENERATION GASTRORETENTIVE BILAYER FLOATING TABLETS OF METFORMIN AND CIPROFLOXACIN.

Anbarasu Murugan[1], Kamal Karunanithi[2], Senthilkumar krishnan[3], Kannabirran Vaikundam[4].
[1234]Department of Pharmaceutics, Kamalakshi Pandurangan College of Pharmacy, Ayyampalayam, Tiruvannamalai, Tamilnadu, India.
indiakbv@gmail.com

Gastroretentive floating drug delivery systems (FDDS) provide a promising platform to enhance the bioavailability and therapeutic performance of drugs with a narrow absorption window in the upper gastrointestinal tract. In this work, a novel bilayer floating matrix tablet combining Metformin Hydrochloride (Met HCl) and Ciprofloxacin Hydrochloride (Cip HCl) was developed, characterized, and evaluated to achieve prolonged gastric retention and controlled dual-drug release. Each layer was formulated using hydrophilic polymers (HPMC K4M / K15M) and an effervescent gas-generating system (sodium bicarbonate + citric acid) to ensure buoyancy. Precompression evaluation of powder blends (angle of repose, bulk/tapped density, Carr's index) confirmed suitable flow properties. Tablets were compressed and assessed for physical parameters (weight variation, hardness, friability, thickness) and content uniformity of both drugs using UV and HPLC methods. Floating behavior was studied in 0.1 N HCl at 37 ± 0.5 °C: the optimized formulation exhibited a floating lag time < 2 min and remained buoyant > 10–12 h. In vitro dissolution studies (USP II, 50 rpm) showed release of Met HCl and Cip HCl governed by diffusion and erosion mechanisms, with ~25–30% release at 1 h, ~60–70% at 6 h, and > 85% by 10 h. Release kinetics fitted best to Korsmeyer–Peppas (non-Fickian transport). The developed bilayer floating tablet holds promise as a dual-drug FDDS with favorable mechanical strength, buoyancy, and sustained release, potentially improving patient compliance in combined antidiabetic and antimicrobial therapy.

**Keywords**: Floating Drug Delivery System; Metformin Hydrochloride, Ciprofloxacin Hydrochloride, Bilayer Matrix Tablet, Controlled Release.

## SMART HYDROGEL-ENHANCED INFLAMMATORY BOWEL DISEASE (IBD) THERAPY: A SYNERGISTIC APPROACH WITH BUDESONIDE, CURCUMIN, AND PROBIOTICS

M Padmasree, B A Vishwanath
Aditya Bangalore Institute of Pharmacy Education and Research, Department of Pharmaceutics, Rajiv Gandhi University of health sciences, Bangalore.
padmasree@adityapharmacy.in

Inflammatory Bowel Disease (IBD) is a chronic gastrointestinal disorder with high relapse rates, limited therapeutic success, and gut microbiota imbalance. Budesonide, although effective, causes systemic side effects,

ISBN: 978-81-980623-8-3

while curcumin suffers from poor solubility and bioavailability. Probiotics facilitate the gut homeostasis restoration, gut probiotic instability is a significant challenge. A smart hydrogel integrating these agents offers a novel multifunctional therapeutic strategy. The present work focuses on the development and evaluation of a colon-targeted smart hydrogel encapsulating budesonide, curcumin, and probiotics to achieve controlled release, enhanced therapeutic efficacy, and improved microbiome modulation. A pH-sensitive hydrogel based on alginate, chitosan, and guar gum was prepared and optimized. Budesonide and curcumin were loaded during gelation, while probiotics (Lactobacillus sp.) were encapsulated under mild conditions. The formulation was characterized for swelling behavior, encapsulation efficiency, morphology (SEM), and thermal/chemical stability (FTIR, DSC). In-vitro release was studied in simulated gastrointestinal fluids, and probiotic survivability was tested by plate count method. The hydrogel achieved high encapsulation efficiency (budesonide 82%, curcumin 78%, probiotics 75%), pH-dependent swelling, and colon-targeted release with ~75% drug release at colonic pH over 24 h. Probiotic viability was retained at >72% after simulated GI transit. In vitro assays showed ~65% reduction in TNF-α and IL-6 levels, confirming strong anti-inflammatory action. These findings highlight the hydrogel as a promising triple-action platform for synergistic IBD therapy, combining corticosteroid efficacy, natural antioxidant protection, and microbiome restoration.

**Keywords**: Smart hydrogel, IBD, Budesonide, Curcumin, Probiotics, Colon-targeted therapy.

## PHARMACOKINETIC EVALUATION OF BUDESONIDE CORE-IN-CUP TABLETS DESIGNED FOR COLON DELIVERY USING LC-MS/MS

M. Pooja, V Saikishore
Bapatla College of Pharmacy,Bapala ,Andhra Pradesh
poojaramesh1115@gmail.com

Budesonide is a widely used drug for the treatment of active inflammatory bowel disease (IBD). In this study, core-in-cup tablets were developed to achieve a prolonged release of Budesonide, aiming to alleviate the symptoms of IBD more effectively. The primary objective was to investigate the pharmacokinetic differences between an optimized core-in-cup tablet formulation and pure Budesonide suspension.Based on uniform and reliable in-vitro drug release profiles, in-vivo evaluation studies were carried out. Various pharmacokinetic parameters were compared to analyze the mean plasma drug concentration–time curves. Two groups of white New Zealand rabbits (n = 6) were used in a cross- over design, with both formulations administered orally. Plasma Budesonide concentrations were quantified using the LC-MS/MS method. The pharmacokinetic comparison revealed significant differences in plasma drug levels between the two formulations. The core-in-cup tablet demonstrated an initial lag phase, indicating delayed release. Notably, the mean residence time (MRT) of the core-in-cup formulation was longer than that of the suspension, suggesting prolonged drug retention.The area under the curve (AUC) for the pure drug suspension was 154.1 ± 1.44 ng·h/mL, while the optimized core-in-cup formulation showed a significantly higher AUC of 918.2 ± 3.11 ng·h/mL. This represents a six-fold increase in bioavailability for the optimized formulation. In conclusion, the core-in-cup tablet formulation significantly improved the bioavailability and pharmacokinetic profile of Budesonide and may serve as a promising chronotherapeutic approach for the management of inflammatory bowel disease.

**Keywords**: LC-MS/MS, Budesonide, Core-in-Cup Tablet, In-vivo Studies, Inflammatory Bowel Disease, Pharmacokinetics

## A QUALITY BY DESIGN CONCEPT ON POLYMERIC MICROPARTICLES CONTAINING ANTIPSYCHOTIC DRUG: SCREENING DESIGN AND OPTIMIZATION USING RESPONSE SURFACE METHODOLOGY

MEETA N JAIN

Discontinuation and poor adherence to oral medications present significant challenges in treating psychosis. Non-compliance can lead to worse outcomes and increased relapse risk. Long-acting injectable antipsychotics (LAAs), also known as depots, improve medication adherence and offer a therapeutic alternative for treating schizophrenia in patients with limited insight or poor adherence. These drugs are widely accepted as they enhance medication compliance and simplify treatment protocols. This study aimed to apply Quality by Design (QbD) to microspheres containing Asenapine maleate (AM) to identify critical process and formulation variables impacting product quality, such as particle size (PS) and entrapment efficiency (EE). A risk assessment using an Ishikawa diagram and preliminary investigation of critical variables were conducted. Two statistical designs were used to optimize critical variables affecting product quality attributes. The Plackett Burman Design (PBD) screened eight variables, showing that drug-polymer ratio, surfactant concentration, and sonication time significantly influenced PS and EE. These factors were optimized using Central Composite Design (CCD), a response surface methodology, to evaluate their effects on PS and EE. A design space was identified, and implementing a control strategy generated the desired product quality. Analysis of design space robustness predicted that formulation must be prepared within established parameters to minimize batch variations. Results demonstrated that applying QbD approach and formulation parameters successfully produced microspheres with appropriate particle size, morphology, enhanced drug content, entrapment efficiency, and desirable drug release profile for depot formulation.

## FORMULATION DEVELOPMENT AND EVALUATION OF NOVEL DRUG DELIVERY SYSTEM

Thorat R.D, Rananaware R.D, Athawale R.B,
Principal K. M. Kundanani College of Pharmacy, Mumbai. Plot No. 23, Jote Joy Building, Cuffe Parade, Mumbai, Maharashtra 400005.
rajthoratpharma@gmail.com

Mouth dissolving films are an advanced oral drug delivery platform designed to rapidly disintegrate upon contact with saliva, offering ease of administration, improved patient compliance and potential for faster onset of action. They are particularly valuable for pediatric, geriatric and psychiatric patients with swallowing difficulties. In this study, mouth dissolving films were developed and optimized for psychosis management using a Quality by Design framework to ensure robust formulation performance. Key formulation variables polymer type, plasticizer concentration and solvent selection were systematically investigated using solvent casting techniques and statistically optimized with Design-Expert® software. The research incorporated a comprehensive literature review, highlighting the advantages of mouth dissolving films in delivering poorly soluble and sensitive drugs. Experimental evaluations included mechanical strength folding endurance, drug release profiles diffusion studies, disintegration time and organoleptic assessment. ANOVA results revealed plasticizer concentration as the most significant factor positively influencing folding endurance ($p = 0.0018$), while solvent concentration and polymer solvent interactions exerted significant negative effects on drug diffusion ($p = 0.0151$). Three factor interactions also played a notable role in mechanical property optimization. The optimized mouth dissolving films formulation demonstrated excellent flexibility, rapid disintegration within seconds, high drug release efficiency and acceptable taste masking attributes essential for psychiatric patient adherence. This work not only establishes a statistically validated formulation strategy for psychosis targeted mouth dissolving films but also provides a scalable manufacturing framework aligned with regulatory Quality by design principles.

**Keywords**: Mouth dissolving films, psychosis, Quality by Design, solvent casting, folding endurance, drug diffusion and patient compliance.

**PC-940**

## FACTORIAL DESIGN IN DEVELOPMENT & IN-VITRO EVALUATION OF DIPHENHYDRAMINE HCL TRANSDERMAL PATCH

AVNI PRAVINBHAI DESAI

The objective of this study was to develop a Diphenhydramine HCl transdermal patch using HPMC K100M as a polymer to overcome the limitations of conventional oral dosage forms. Transdermal delivery offers advantages such as controlled release, avoidance of first-pass metabolism, and improved patient compliance. A Quality by Design (QbD) approach was employed to establish a robust manufacturing process, ensuring consistent product quality within the defined Quality Target Product Profile (QTPP) and design space. This strategy emphasizes building quality into the formulation rather than relying solely on end-product testing. The pharmaceutical target profile was to obtain a safe,

ISBN: 978-81-980623-8-3

effective, and patient-friendly patch capable of delivering Diphenhydramine HCl in a controlled manner. Transdermal patches were prepared by solvent casting using HPMC K100M and PEG 400 as the polymer and plasticizer, respectively. Preliminary batches guided the selection of variables for a three-level factorial design to optimize formulation parameters. The prepared patches were evaluated for physical characteristics (thickness, weight variation, pH), drug content, in vitro diffusion, and stability under storage and packaging conditions. The optimized formulation demonstrated desirable physicochemical and release properties, indicating its potential as a promising alternative to conventional Diphenhydramine HCl dosage forms.

**AN OVERVIEW OF NANOEMULSION**

SWAPNALI SURYVAVANSHI

A novel drug delivery system has been developed to address the limitations of conventional drug delivery methods. This comprehensive review explores the nanoemulsion system. The interest in nanoscale emulsions has considerably grown in recent decades as a consequence of their specific attributes such as high stability, attractive appearance, in addition to high performance and sensorial advantage. In fact, it nanoemulsions are one of the major popular formulations systems in the pharmaceutical and cosmeceutical fields.Nanoemulsions are colloidal dispersion systems that are thermodynamically stable, composed of two immiscible liquids mixed along with emulsifying agents.

**Keywords**: Nanoemulsion, novel drug delivery, emulsifying agents etc.

**DEVELOPMENT AND OPTIMIZATION OF BACOSIDE A LOADED THERMOSENSITIVE IN-SITU HYDROGEL FOR ACUTE WOUND HEALING**

DATIR MAHENDRA BABAN

To develop and optimize a thermosensitive in-situ hydrogel containing Bacoside A for enhanced wound healing, focusing on optimal gelling characteristics, mucoadhesion, and antimicrobial efficacy. Thermosensitive hydrogels were formulated using Poloxamer 407 and xanthan gum through statistical optimization. Formulations were characterized for physicochemical properties, drug content, rheology, and mucoadhesion. Response surface methodology optimized gelling temperature and mucoadhesive strength. Ex-vivo permeation studies were conducted, followed by stability assessment and antimicrobial evaluation against E. coli and S. aureus. The optimized formulation (RF6) exhibited ideal gelling temperature (33.78±0.78°C), mucoadhesive strength (2989.5±0.284 dyne/cm$^2$), and viscosity (3185±0.923 cps). The statistical model showed high predictability ($R^2$>0.999) for both responses. Ex-vivo studies demonstrated sustained drug release with 96.67±0.88% permeation at 8 hours and flux of 11.59 µg/cm$^2$/h. The formulation showed significant antibacterial activity with zones of inhibition of 24.3±0.62 mm (E. coli) and 23.8±1.06 mm (S. aureus), comparable to the marketed standard. Stability studies confirmed product integrity over six months with minimal variation in critical parameters. The developed Bacoside A thermosensitive in-situ hydrogel demonstrates promising characteristics for wound healing applications, combining optimal gelling properties, sustained drug release, and significant antimicrobial activity, offering a potential alternative to conventional wound healing formulations.

**Keywords**: Bacoside A, Thermosensitive hydrogel, In-situ gelling, Wound healing, Response surface methodology, antimicrobial activity.

**PC-943**

**FORMULATION AND EVALUATION OF POLYHERBAL DISPERSIBLE TABLETS FOR ENHANCED BIOAVAILABILITY AND THERAPEUTIC EFFICACY**

SUVARNA GULABRAO BHOKARE

The aim of the present study was to transform Ayurvedic formulation into modern dosage form such as poly-herbal dispersible tablet for skin-enhancing and cosmetic properties. The goal is to offer a natural, stable, and effective oral supplement for beauty from within. Dispersible tablets were prepared using powder of the selected plant viz. Moringa Oliferia Lam., Catechin and Naringin with the help of Superdisintegrants addition technique using Sodium Bicarbonate, Citric acid, Magnesium stearate, Microcrystalline cellulose and Sodium saccharine in different percentage. Evaluation assessments such as the substantial test, weight variation, hardness, friability, content uniformity, disintegration, in vitro dispersion, stability study and IR compatibility were carried out. For every manufacturing process, the micromeritics of the extract powdered form were found to be good, indicating good flow characteristics. The drug content was about 100% in all compositions and an extensive investigation produced an outcome that complied with official requirements for the homogeneity test. All formulations had disintegration times, with the polyherbal formulation-5 (PHF-5) exhibiting 2.00±0.80. There is no chemical interaction between the extracts and excipients, according to the IR compatibility. The PHF-5 demonstrated an appropriate in vitro dispersion time and was deemed the best formulation. The PHF may be a novel, easily swallowed readily dispersed tablet that improves pharmaceutical permeability and advances their bioavailability according to the stability research and FTIR friendliness. Hence formulation maintains bioactivity while improving absorption and convenience.

**Keywords**: FTIR, compatibility study, Dispersion time, Superdisintegrants, Polyherbal dispersible tablet, Micromeritics.

**PC-944**

**IMPACT OF NANOTECHNOLOGY IN TARGETED DRUG DELIVERY SYSTEM**

Sadaf Rafik Ansari, Rajat Sayyed
MCES's Dr.Pa Immandar University

Nanotechnology has emerged as a revolutionary tool in targeted drug delivery systems, offering precise and controlled delivery of therapeutic agents to specific sites in the body. Nanoparticles such as liposomes, dendrimers, and polymeric carriers enhance drug stability, solubility, and bioavailability while minimizing side effects. These systems enable site-specific drug accumulation, especially in cancer therapy and chronic diseases, thus improving treatment efficacy and reducing systemic toxicity. Controlled drug release and the potential for personalized medicine make nanotechnology a promising approach in modern therapeutics. However, challenges such as toxicity, large-scale production, and regulatory issues need to be addressed for its widespread clinical application. Overall, nanotechnology-based drug delivery systems represent a paradigm shift in the pharmaceutical field with vast potential for future advancements.

**Keywords**: Nanotechnology, Drug Delivery, Targeted Therapy, Nanoparticles, Controlled Release

**PC-945**

**DEVELOPMENT OF FAST DISSOLVING TABLETS FOR ENHANCED DRUG DELIVERY**

Mohammad Hadi Zameer Shaikh

Fast dissolving tablets (FDTs) have emerged as a promising drug delivery system, particularly for patients who experience difficulty in swallowing conventional tablets or capsules. The present study focuses on the formulation and evaluation of FDTs to improve the onset of action, enhance bioavailability, and ensure better patient compliance. A model drug was selected and formulated using direct compression techniques, incorporating superdisintegrants such as sodium starch glycolate, croscarmellose sodium, and crospovidone in varying concentrations. Pre-compression parameters such as flow properties of the powder blend were assessed, followed by post-compression evaluations including hardness, friability, disintegration time, and in-vitro drug release. Among the formulations tested, the batch containing 4% crospovidone demonstrated the fastest disintegration time and highest drug release profile within 15 minutes, making it the most effective.

**Keywords**: Fast dissolving tablets, drug delivery system, disintegration time, bioavailability, pharmaceutical formulation, patient compliance

**PC-946**

**GELS, CREAMS AND LOTIONS: A WAR OF WHO GETS ABSORBED FASTER**

Rajat Sayyed, Rubab raza Mir

Welcome to the battlefield of topical drug delivery, where three legendary warriors gels, creams, and lotions — compete not for love, but for absorption supremacy. While patients just want quick relief and soft skin, these formulations have their own drama going on behind the scenes. This abstract takes you through their silent war, judged not by weapons, but by spreadability, viscosity, elegance, and of course, who

ISBN: 978-81-980623-8-3

gets absorbed the fastest without turning your skin into a greasy dosa. Gels walk in like cool kids — clear, quick-drying, and non-sticky. They don't just deliver the drug efficiently, they leave behind zero residue and 100% attitude. Creams are the grandmas of formulations slow, thick, but deeply nourishing. They take their time but heal like magic lotions? They try to please everyone light like water, but sometimes too gentle to be remembered. In this study, multiple formulations were evaluated for parameters like pH, viscosity, drug release profile, and user satisfaction. Results showed gels winning the absorption race, creams winning the hydration game, and lotions getting sympathy votes for effort. Every cream formulation is like a tragic love story — sometimes the oil phase overpowers, sometimes the water runs away, and the poor emulsifier is stuck in the middle trying to keep the relationship together. But when the balance is just right, the result is magical skin is happy, science wins, and even your pharmacist smiles a little. This topic is a reminder that behind every soft touch is some hard-core chemistry. But jokes apart, each formulation plays a vital role in delivering drugs transdermally. The ideal choice depends on the therapeutic need, patient type, and application area. Through this sarcastically serious exploration, we learned one thing — the fight to be the best isn't just in politics or Bollywood, it's alive and well in pharmacy labs too. So next time you pick a gel, cream, or lotion just know, a whole war was fought for that moment on your skin.

**PC-947**

## FORMULATION AND EVALUATION OF IBUPROFEN TABLETS: A COMPARATIVE STUDY OF DIRECT COMPRESSION AND WET GRANULATION TECHNIQUES

Rahima Shaikh, Rajat Sayyed

Ibuprofen, a widely used non-steroidal anti-inflammatory drug (NSAID), is commonly employed for its analgesic, antipyretic, and anti-inflammatory properties. Due to its poor aqueous solubility and potential gastric irritation, optimizing its oral dosage form is crucial to ensure better patient compliance and therapeutic efficacy. This research focuses on the formulation and evaluation of ibuprofen tablets using two different techniques—direct compression and wet granulation—to determine the most effective approach for enhancing tablet performance. The study involved preformulation analysis of ibuprofen, including drug-excipient compatibility using FTIR and thermal analysis. Tablets were prepared with various excipients such as microcrystalline cellulose, starch, and sodium starch glycolate. The formulated batches were evaluated for physicochemical parameters such as hardness, friability, disintegration time, weight variation, and drug content uniformity. In vitro dissolution studies were conducted to compare the release profiles of both formulations. The results indicated that tablets prepared by wet granulation exhibited superior mechanical strength and more consistent drug release compared to those prepared by direct compression. Dissolution efficiency was significantly higher in the wet granulated formulation, indicating better bioavailability potential. The study concludes that wet granulation is a more effective technique for ibuprofen tablet formulation, offering improved drug release and overall quality.

**Keywords**: Ibuprofen, NSAIDs, tablet formulation, wet granulation, direct compression, evaluation, dissolution profile

## FORMULATION OF EVOLUTION OF SUSTAINABLE TABLET

Farhat Abdul Qadir Chamanshaikh

Now a days as very few antidiabetic drugs are coming out of research and development and some existing drugs are showing several side effects when administered orally, multiple times in a day, hence change in the operation is a suitable and optimized way to make some drug more effective by slight alteration in the drug delivery. Matrix type drug delivery systems of an antidiabetic drug like Metformin Hydrochloride, is an interesting and promising option when developing an oral sustained release system. An appropriately designed controlled release drug delivery system can be a major advance towards solving problems concerning the targeting of a drug to a specific organ or tissue and controlling the rate of drug delivery to the target sites. This research work is made in designing of sustained release dosage form of Metformin Hydrochloride by wet granulation method employing both Xanthan Gum and Hydroxy Propyl Methyl Cellulose (HPMC K4M) as a rate controlling polymer. The development of oral sustained release systems has been a challenge to formulation scientists due to their inability to restrain and localize the system at targeted areas of the gastrointestinal tract. From all the formulation trial batches, formulation F7 shows the best results. It has been observed that HPMC K4M alone cannot give satisfactory drug release profile but the blend of HPMC K4M and Xanthan gum together give the best drug release kinetics. Diabetes is one of the major causes of death and disability in the world. Diabetes is a long-lasting health condition that affects how our body turns food into energy. If you have diabetes your body does not make enough insulin that cause serious health problems, like heart disease, vision loss and kidney disease. Diabetes mellitus are be classified into two main types. First is type I or juvenile diabetes which is also called as insulin dependent diabetes and second type is type I or non-insulin dependent diabetes mellitus, this Type II diabetes is most common type of diabetes. Oral drug delivery is the most widely utilized route of administration among all the routes [nasal, ophthalmic, rectal, transdermal and parenteral routes] that have been explored for systemic delivery of drugs via pharmaceutical products of different dosage form. Oral route is considered most natural, uncomplicated, convenient and safe, due to its cease of administration, patient acceptance, and cost-effective manufacturing process [1-3].

## IMPROVING BIOAVAILABILITY OF POORLY WATER-SOLUBLE DRUGS - ENHANCING THE EFFECTS OF MEDICATION

Ansari Fizanaaz Rashid, Swapnil Dounde
Allana College Of Pharmacy, Pune

Poorly water-soluble drugs pose a significant challenge in pharmaceutical development due to their low bioavailability, which can lead to reduced efficacy and increased side effects. This abstract proposes strategies to improve the bioavailability of poorly water-soluble drugs, thereby enhancing the effects of medication. Various techniques such as nanocrystal formulation, lipid-based delivery systems, and cyclodextrin complexation will be explored to increase the solubility and bioavailability of poorly water-soluble drugs. These techniques have shown promise in improving the bioavailability of poorly water-soluble drugs. Enhanced bioavailability, improved therapeutic efficacy, and reduced side effects are expected outcomes of this approach. This can lead to better patient outcomes and improved quality of life. Improving the bioavailability of poorly water-soluble drugs can lead to reduced healthcare costs and improved quality of life. This is a crucial area of research in the pharmacy industry, with potential applications in various therapeutic areas. The techniques mentioned above have shown promise in improving the bioavailability of poorly water-soluble drugs. For instance, nanocrystal formulation can increase the surface area of the drug, allowing for better dissolution and absorption. Lipid-based delivery systems can also enhance the bioavailability of poorly water-soluble drugs by solubilizing them in lipids. Cyclodextrin complexation is another technique that can improve the solubility and bioavailability of poorly water-soluble drugs. Overall, improving the bioavailability of poorly water-soluble drugs is a vital area of research that can have a significant impact on the pharmacy industry and patient outcomes. Further research is needed to explore the potential of these techniques and to develop new strategies for improving the bioavailability of poorly water-soluble drugs.

**Keywords**: Bioavailability, poorly water-soluble drugs, nanocrystal formulation, lipid-based delivery systems, cyclodextrin complexation.

## FORMULATION AND CHARACTERIZATION OF METOPROLOL SUCCINATE EXTENDED RELEASE TABLETS USING POULTRY EGG SHELL POWDER AS A MATRIX BASE

SANJIBAN SARKAR, Nityananda Mondal 1, Chowdhury Mobaswar Hossain 2
Department of Pharmaceutics, B.C.D.A. College of Pharmacy & Technology, 78/1, Jessore Road (S), Hridaypur, Kolkata- 700127, West Bengal, India

Advancements in dosage form technologies over the years led to many novel drug delivery systems such as osmotic pumps, matrix tablets, multi-layered coatings, expanding the potential of extended release tablets. Advanced analytical techniques made sure extended release

ISBN: 978-81-980623-8-3

formulations are now mostly employed for long-term therapeutic management of cardiovascular, neurological, and psychiatric disorders. Metoprolol succinate which is an antihypertensive, selectively blocks β1-adrenergic receptors in the heart, reducing heart rate, cardiac output, and blood pressure. The present study aimed at formulation of extended release tablets of Metoprolol succinate using processed poultry egg shell powder as a matrix base. Preformulation studies, micromeritics, high end instrumental analysis, microbiological studies performed on processed poultry egg shell powder suggested that it can be used as a matrix base for tablets. Metoprolol succinate tablets were formulated using processed poultry egg shell powder as matrix base and other standard pharmaceutical excipients via direct compression using 8 station rotary tablet press. The compressed tablets were then evaluated for various official and unofficial tests. Release studies performed on the prepared Metoprolol succinate tablets followed an extended-release profile, with an initial slow release followed by a steadier, consistent drug release over time. The release appeared to be linear over time, reaching 100% release by 4 hours. The gradual increase in cumulative drug release suggested that this formulation was an extended-release or sustained-release formulation. The study carried out till now suggested, processed poultry egg shell powder might be a potential matrix base for sustained release tablets.

**Keywords**: Extended release, matrix base, Processed

**PC-951**

**EXOSOMES: EMERGING NANOCARRIERS IN DIAGNOSIS AND THERAPY TINY MESSENGERS WITH BIG IMPACT**

PRAKRITI DIWAN UPADHYAY

Exosomes are nanoscale extracellular vesicles (30–150 nm) secreted by most cells, functioning as natural carriers of proteins, lipids, and nucleic acids. They play a pivotal role in intercellular communication and are increasingly recognized as promising tools in biomedical research. Owing to their unique biogenesis, lipid bilayer structure, and ability to cross biological barriers such as the blood–brain barrier, exosomes demonstrate superior stability and biocompatibility compared to synthetic nanocarriers. Recent advancements highlight their potential in diverse applications including targeted drug delivery, cancer immunotherapy, regenerative medicine, and disease diagnostics, particularly through exosomal biomarkers. Despite significant progress, challenges remain in large-scale standardized production, isolation techniques, and clinical translation. Future research is focused on engineering exosomes for personalized medicine and establishing regulatory frameworks for their therapeutic application. Overall, exosomes represent a transformative platform with immense potential to revolutionize diagnosis and treatment in modern healthcare.

**PC-952**

**CHALLENGES AND INNOVATION OF TRENDS IN BIOLOGICS PHARMACEUTICAL FORMULATION**

BIJAYA LAXMI KAND

Biopharmaceuticals, derived from biological sources, have revolutionized disease prevention and treatment. This comprehensive review explores the concept, definition, and classification of biopharmaceuticals, encompassing recombinant proteins, monoclonal antibodies, vaccines, and nucleic acids. The paper discusses various applications, including therapy, prevention, and diagnosis, highlighting their role in managing cancer, autoimmune diseases, and infectious disorders. Technological advances in formulation development, such as 3D printing and nanotechnology, are examined. Challenges in stability and regulatory frameworks are addressed. Future trends, including process analytical technology and continuous manufacturing, are discussed. This review provides a thorough understanding of biopharmaceuticals, their development, and their impact on modern medicine. The review also explores economic and social implications, highlighting potential cost savings. Collaboration between industry, academia, and regulatory agencies is emphasized to advance the field, facilitating further research and development in biopharmaceuticals. Overall, this review aims to provide a holistic understanding of biopharmaceuticals and their transformative potential in healthcare. Additionally, the review highlights the importance of personalized medicine and the role of biopharmaceuticals in tailoring treatments to individual patients' needs. Furthermore, the review discusses the potential of biopharmaceuticals in addressing emerging global health challenges, such as pandemics and antimicrobial resistance.

**PC-953**

**FORMULATION AND CHARACTERIZATION OF DSP-LOADED SLNS FOR TARGETED RHEUMATOID ARTHRITIS THERAPY**

AYUSHI SHARMA

An effective glucocorticoid anti-inflammatory, dexamethasone sodium phosphate (DSP) is used to treat inflammatory diseases such as rheumatoid arthritis (RA). Using the microemulsion process, DSP-loaded solid lipid nanoparticles (SLNs) are being developed and evaluated in this work to improve medication delivery in RA treatment. Utilizing the factorial design process, SLNs (SLNs-0 to SLNs-2) were optimized. When the SLNs' physicochemical characteristics were evaluated, they showed well-formed nanoparticles with mean particle sizes between 271 and 112 nm and polydispersity indices (PDI) between 0.34 and 0.14. Chitosan-coated SLNs (CN-SLNs) were chosen for additional investigation because they had a positive zeta potential (+28.4 mV), a PDI of 0.37, and an enhanced particle size of 330 nm. Because of its increased viscosity (875 cP), the CN-SLNs gel was more suitable for topical application. Compared to uncoated SLNs and the drug solution, in vitro drug release experiments showed that the gel formulation with chitosan coating produced slower, longer-lasting release profiles, with release kinetics facilitating regulated drug delivery. Ex vivo skin penetration tests revealed that CN-SLNs and CN-SLNs gel enhanced medication penetration. In vivo tests on rats with induced arthritis showed that topical treatment of the novel formulation significantly reduced inflammation, oedema, and joint diameter when compared to the commercial formulation. All things considered, chitosan-coated DSP-loaded SLNs provide a potent, long-lasting method for improving topical administration and rheumatoid arthritis therapy.

**PC-954**

**QUALITY BY DESIGN IN PHARMACEUTICAL FORMULATION: TOOLS, TRENDS, AND TECHNOLOGIES**

BATTULA VENKATA LAKSHMI

As pharmaceutical industries now a days concerns with the safety and continuously enhance the quality of the drug products. The development of pharmaceutical industries is based on the innovation of the product as well as the manufacturing process by keeping quality in the mind. In earlier times, the development of pharmaceutical products shows the failure in the quality and hence alters the therapeutic effect of the product. Quality by test (QbT) was the only way to maintain the quality of the drug product before the FDA launches the current Good Manufacturing Practices (cGMP), which was an approach without understanding the processes. So FDA decided to applied the several Design of Experiments (DoE) in the pharmaceutical fields. QbD (Quality by design) was one of the design experiment approved by the FDA to maintain the quality of the drug products before reaching to the market. In pharmaceutical industry, QbD brings cost-efficiency and simplicity of manufacturing process into reality. QbD is a systematic risk-based, proactive approach to pharmaceutical development that begins with predefined objectives and emphasizes product and process understanding and process control based on sound science and quality risk management. The main aim of this review is to discuss the concept of pharmaceutical Quality by Design and describe how it can be helpful to ensure pharmaceutical quality & drug development

**FORMULATION AND EVALUATION OF HERBALS AND ANTIMICROBIAL OINTMENT FROM EXTRACTION OF PASSIFLORA EDULIS.**

M.HARISH.GOUD

This study aims to formulate and evaluate an herbal antimicrobial ointment derived from the leaf extract of Passiflora edulis. The extraction process was carried out using a Soxhlet apparatus with ethanol as the solvent. The ethanolic extract was subsequently formulated into three different ointment formulations. Each formulation was assessed for its physical parameters to ensure the ointments' consistency, stability, and suitability for topical application.The antimicrobial efficacy of the formulations was tested using the pour plate method against three different bacterial strains, including Escherichia coli, Bacillus subtilis, and Staphylococcus aureus. The

ISBN: 978-81-980623-8-3

antimicrobial activity was determined by measuring the zones of inhibition. These results were compared to the standard antibiotic ampicillin to evaluate the relative effectiveness of the herbal formulations.

**PC-956**

**FORMULATION, CHARACTERIZATION, AND EVALUATION OF MEFENAMIC ACID–LOADED B-CYCLODEXTRIN NANOSPONGES**

SHRADDHA ARAVIND TAMBE

Mefenamic acid (MFA), a widely prescribed nonsteroidal anti-inflammatory drug (NSAID), suffers from poor aqueous solubility and limited oral bioavailability, leading to variable therapeutic efficacy and gastrointestinal adverse effects. To address these limitations, β-cyclodextrin (β-CD)–based nanosponges were developed as a novel drug delivery system for MFA. Blank nanosponges were synthesized via the melt method using diphenyl carbonate as a crosslinker and optimized through Central Composite Design (CCD). MFA was incorporated using a freeze-drying approach, and the resulting formulations were characterized by FTIR, DSC, PXRD, TEM, particle size analysis, and zeta potential measurements. The optimized MFA-loaded nanosponges exhibited spherical morphology, nanoscale particle size, high entrapment efficiency, and improved amorphous dispersion of the drug. In vitro release studies revealed enhanced solubility and a sustained release profile extending up to 12 hours, with release kinetics best fitting a first-order model. The optimized nanosponges were encapsulated into hard gelatin capsules, which complied with pharmacopoeial standards. Stability studies under accelerated conditions confirmed the robustness of the system, with no significant changes in drug content, particle size, or dissolution profile. These results highlight β-CD nanosponges as a promising delivery platform for improving the solubility, bioavailability, and therapeutic potential of MFA.

**Keywords**: Mefenamic acid, β-cyclodextrin nanosponges, formulation, characterization, sustained release, solubility enhancement, drug delivery

**FORMULATION AND EVALUATION OF MELOXICAM LIQUISOLID COMPACTS**

K T SUNIL KUMAR

Meloxicam, a BCS Class II drug, suffers from poor aqueous solubility, resulting in limited dissolution and variable bioavailability. The present study aimed to enhance the dissolution of meloxicam using the liquisolid compact technique, which employs a non-volatile solvent system and porous carriers to convert liquid medication into a free-flowing, compressible powder. Meloxicam (5% w/w in PEG 400) was incorporated into microcrystalline cellulose (Avicel PH 102) as carrier and Aerosil as coating material in a 15:1 ratio. Sodium starch glycolate (1% w/w) was added as superdisintegrant. The prepared liquisolid systems were compressed into tablets and evaluated for pre- and post-compression parameters including flow properties, hardness, friability, weight variation, disintegration, and in vitro dissolution. The liquisolid powder blend exhibited good flow properties (angle of repose: 15.45°). However, the compressed tablets showed suboptimal mechanical properties (hardness: 2 kg/cm$^2$; friability: 7.14%). Weight variation also failed to comply with IP standards. The average disintegration time was 12.8 minutes. Dissolution studies revealed cumulative drug release of 1.46% for liquisolid tablets compared to 16.04% for pure meloxicam, indicating that extended disintegration limited drug release. Although liquisolid compacts are a promising approach for improving dissolution of poorly soluble drugs, in this study meloxicam formulations showed inferior dissolution compared to pure drug, primarily due to prolonged disintegration time and weak mechanical strength. Optimization of carrier–coating ratio, solvent selection, and superdisintegrant level is required to achieve improved performance.

**Keywords**: Meloxicam, Liquisolid compact, Dissolution enhancement, BCS Class II drugs, PEG 400.

**COMPREHENSIVE CHARACTERIZATION OF BOVINE MILK-DERIVED EXTRACELLULAR VESICLES FOR DRUG DELIVERY NANOPLATFORMS**

Srinivas Hebbar
Department of Pharmaceutics, Manipal College of Pharmaceutical Sciences, Manipal Academy of Higher Education (MAHE), Manipal. Karnataka 576104

Milk-derived extracellular vesicles (MEVs) are nanoscale vesicles rich in bioactive proteins, lipids, and nucleic acids. Owing to their biocompatibility, stability, and ability to cross biological barriers, they hold great potential for drug delivery, nutraceutical, and therapeutic applications. Compared to EVs from other sources, MEVs are abundant, economical, and scalable. Isolation was carried out using PEG precipitation with size exclusion chromatography (SEC). Characterization included dynamic light scattering (Malvern Zetasizer), atomic force microscopy (AFM), nanoparticle tracking analysis (NTA), scanning electron microscopy (SEM), transmission electron microscopy (TEM), and Western blotting for the EV marker TSG101. The preparation yielded MEV with an average particle size of 186.8 nm (Zetasizer) and 184.6 nm (NTA), and a zeta potential of –26.9 mV, indicating good colloidal stability. AFM showed an average height of 101.9 nm. Western blot confirmed TSG101 expression, while SEM and TEM demonstrated spherical morphology with intact membranes. Among the tested methods, PEG coupled with SEC provided the highest purity and structural integrity. The results establish a robust isolation and characterisation workflow, supporting the application of milk Extracellular vesicles as versatile, naturally derived nanocarriers for bioactive molecule delivery.

**FORMULATION OF ORO-DISPERSIBLE FILM COMPRISING BRAHMI (BACOPA MONNIERI) AND SHANKHPUSHPI (CONVOLVULUS PLURICAULIS) FOR NEUROCOGNITIVE ENHANCEMENT**

DOLLY ARUN BHENDE

Neurocognitive disorder is a general medical term for decreased mental function, mental fatigue and attention disorders. This disorder increasing prevalently in both young and elderly populations due to lifestyle stress, aging and neurodegenerative conditions. Although Brahmi and Shankhpushpi is well-documented Ayurvedic herb known for its memory enhancing and neuroprotective properties. Its traditional dosage form such as tablets and capsules faces several challenges including low bioavailability, delayed onset of action and poor patient compliance, particularly among children and geriatric patients. To address these limitations, this study explores the formulation of Oro-dispersible films (ODFs) containing standardized Brahmi and Shankhpushpi extract as a novel drug delivery system. The ODF of Brahmi and Shankhpushpi provides an effective solution to the limitations of conventional dosage forms, offering a rapid, convenient and patient-friendly method for neurocognitive enhancement. This study focused on the development and evaluation of Oro-dispersible films (ODFs) containing Brahmi and Shankhpushpi for improving memory and cognitive performance. Standardized extracts of Brahmi and Shankhpushpi were formulated into thin films using the solvent casting technique, with film-forming polymers along with suitable plasticizers, sweeteners and flavoring agents. The prepared films were evaluated for their physicochemical

ISBN: 978-81-980623-8-3

characteristics as well as functional parameters. This study concludes that Brahmi and Shankhpushpi loaded ODFs hold significant potential as a patient friendly herbal delivery system for memory boosting activity combining traditional Ayurvedic benefits with modern pharmaceutical technology.

**DEVELOPMENT OF NOVEL CO-CRYSTAL OF IVERMECTIN FOR IMPROVED TOPICAL TREATMENT OF SKIN INFECTIONS**

SARBANI ROY

Ivermectin (IVM) is a broad-spectrum antiparasitic agent effective against ectoparasitic skin infections such as scabies, but its therapeutic potential is limited by poor aqueous solubility (~4 µg/mL) and high lipophilicity, the lipophilic stratum corneum, the outermost layer of the skin, favors the entry of lipid-soluble compounds, excessive lipophilicity can cause a drug to "stick" to this barrier rather than partitioning into and permeating through it, leading to reduced overall permeability which hinder dermal penetration and topical bioavailability. This study explores pharmaceutical cocrystallization as a novel strategy to enhance the solubility, stability, and topical delivery of IVM. Cocrystals of IVM with GRAS coformers—glycine, caffeine, and nicotinamide—were synthesized using solvent evaporation and co-grinding methods, and confirmed via powder X-ray diffraction, DSC, and FTIR. The optimized cocrystals demonstrated improved solubility and dissolution compared to pure IVM. Among them, the IVM–glycine cocrystal was incorporated into a hydroxyethylcellulose gel base (1% w/w) for topical application. The cocrystal gel exhibited desirable physicochemical characteristics, including suitable pH, viscosity, spreadability, and uniform drug loading. In vitro release and ex vivo Franz diffusion studies demonstrated significantly enhanced drug release and skin permeation from the cocrystal gel compared to conventional IVM gel. Animal skin irritation studies revealed no signs of erythema or edema, confirming its dermal safety. Overall, the development of IVM cocrystals and their incorporation into a topical gel formulation effectively addressed solubility and permeability challenges, offering a promising approach for improved topical therapy of skin infections such as scabies. This work highlights the potential of cocrystal engineering in designing stable, safe, and clinically relevant formulations for poorly soluble drugs.

**3D PRINTING OF MEDICINES**

Saba Mahara

The idea of patient-specific medicine has been around for a long, but it has gained a lot of attention lately. There is an increase in demand for 3D printing of medicines, which is also known as additive manufacturing, is an innovative technology that allows for creation of customized drug and dosage formulations. 3D printing of medicine involve sequential layering of formulation of 3D objects. Fused Deposition Modeling (FDM), Stereolithography (SLA), Selective Laser Sintering (SLS), INKJET Printing are the recent techniques used in 3D Printing. This technology helps in opening on-demand manufacturing, reducing depending on large scale production and supply chains. 3D Printing of medicine allows precise fabrication of customized drug dosages, complex release profiles and patient specific formulation, thus by producing accuracy in the dosage or drug formulations and also making drugs more precise, personalized and patient-friendly. Simultaneously, Artificial intelligence in the 3D printing helps in customizes the drug or dosage as per the data of patient (age, weight), creates a drug or tablet in such a way that it should be complex (has different types of drug present in it), the drug or formulation made from 3D Printing is precise accurate and dose adjustable and also control speed and temperature during production to not to get the material flow. AI also identifies the defects during printing of drug to maintain safety and efficacy standards. Some of the AI tools include M3DISEEN, FABRX etc. Therefore this make sures improved treatment, safety and better patient adherence. Personalised medicine, Patient approval, Improvement in pre visualization Cost effective, Drug development and production and many more. In this selection of right drug and plan its dose,shape and release profile and design is made according to patients need the drug and excipient are mixed with each other and forms a material which has to be printed (maybe powders,paste or liquid). The printed medicine is subjected to drying,its gets stabilized. Then the medicines are weight,their accuracy is checked and safety measures Now the printed medicine is packed and given to patient 3D Printing of medicines is approaching up a new cycle in healthcare by making therapies more effective and accurate With the help of AI this technology can create medicine that fit into patient necessity , while also secure safety and accuracy during creation. It decreases dependency on mass development of drugs and focuses on creating medicines that are easier to use , more potent and fit to each person..Therefore 3D Printing and AI have the power to alter how medicines are prepared and delivered,making treatments life –saving and patient adjustable and friendly

**PHOSPHOLIPIDS FROM DAIRY WASTE FOR CARRIER SYSTEM IN PHARMACEUTICAL INDUSTRY**

ANMOL KHUSHALRAO DHAWANDE

Phospholipids, a critical class of bioactive lipids, possess diverse applications in pharmaceuticals, food, and cosmetic industries due to their amphiphilic nature. This study focuses on the isolation and characterization of phospholipids from ghee residue, a by-product of dairy processing, offering an innovative approach for value addition to waste materials. The extraction process utilized a solvent-based method optimized to yield a high-purity phospholipid fraction. Thin-layer chromatography (TLC) and Total phospholipid content (TPC) analysis validated the purity and concentration of the isolated phospholipids. Fourier-transform infrared spectroscopy (FTIR) provided insights into the functional groups and chemical bonding patterns, confirming the characteristic phospholipid structure. Liquid chromatography-mass spectrometry (LC-MS) was employed to determine the molecular composition, revealing the presence of distinct phospholipid classes. Differential scanning calorimetry (DSC) assessed the thermal behavior, highlighting the stability and transition temperatures of the compounds. X-ray diffraction (XRD) further elucidated the crystalline properties and structural integrity. This study promotes sustainable practices by converting an underutilized by-product into a value-added resource, contributing to both environmental conservation and industrial innovation.

**CURRENT SCENARIO OF BONE-RELATED DISORDERS**

Kamala Chandak, Vinita Kale
Smt. Kishoritai Bhoyar College of Pharmacy, Kamptee

Bone related disorders like osteoporosis, osteoarthritis, rheumatoid arthritis, fractures, and bone cancers are a growing worldwide health problem, particularly for the elderly, causing significant illness, physical limitations, and expensive healthcare. Osteoporosis affects more than 200 million people globally, particularly postmenopausal women and elderly men. Osteoarthritis, the most common joint disorder, affecting about 528 million people worldwide. This broad category of diseases leads to issues such as weakened or brittle bones, joint degeneration,

ISBN: 978-81-980623-8-3

and structural bone damage, resulting in widespread disability and a substantial economic burden on societies. These conditions contribute to widespread illness, chronic pain, and significant long-term disabilities, limiting individuals' ability to perform daily activities. The high rates of fractures and associated long-term complications result in considerable healthcare costs, placing a substantial economic strain on individuals and healthcare systems globally. Bone loss is a natural part of aging, making individuals more susceptible to disorders like osteoporosis. The increasing number of aging Indians, a group vulnerable to accelerated bone loss, is worsening the country's bone disease burden. Risk factors include poor diet, nutritional deficiencies (e.g., vitamin D, calcium), lack of sunlight, inactivity, being female, low BMI, and unawareness. To combat this, India needs urgent interventions like food fortification, Vitamin D and calcium supplementation, lifestyle changes, and better access to screening and treatment to address infrastructure and awareness gaps.

## ENGINEERED 3D-PRINTED NIOSOMAL PILOCARPINE INSERTS FOR PROLONGED INTRAOCULAR PRESSURE REDUCTION IN GLAUCOMA

Pankaj R Dhapake, Jagdish R Baheti
Kamla Nehru College of Pharmacy, Butibori Nagpur 441122, Maharashtra, India.
pankajdhpk4@gmail.com

Glaucoma management requires consistent and sustained reduction of intraocular pressure (IOP), yet conventional pilocarpine eye drops are limited by rapid precorneal elimination, brief ocular residence time, and the need for multiple daily administrations. These limitations often lead to poor adherence and suboptimal therapeutic outcomes. The present study focuses on the development of 3D-printed niosomal Pilocarpine HCl ocular inserts aimed at achieving prolonged and controlled drug release for enhanced glaucoma therapy. Pilocarpine-loaded niosomes were formulated using an optimized combination of surfactant and cholesterol, and evaluated for vesicle size, distribution, entrapment efficiency, zeta potential, and in-vitro release kinetics. The optimized niosomal system was incorporated into custom-designed 3D-printed biodegradable inserts, allowing precise control over insert geometry, drug loading, and mechanical characteristics. The fabricated inserts were assessed for surface morphology, mucoadhesion, swelling behavior, mechanical strength, and stability under accelerated conditions. In-vitro release studies demonstrated a markedly sustained and predictable release profile of Pilocarpine HCl from the 3D-printed matrix compared to conventional dosage forms. In vivo evaluation in experimental animal models further confirmed a significant and extended reduction in intraocular pressure, along with excellent ocular biocompatibility and absence of irritation or adverse effects. Overall, the findings highlight that 3D-printed niosomal Pilocarpine HCl ocular inserts represent an innovative, patient-friendly, and efficient ocular drug delivery platform. This approach offers improved bioavailability, reduced dosing frequency, enhanced patient compliance, and substantial potential for advancing long-term glaucoma therapy.

## FORMULATION AND EVALUATION OF POLYHERBAL MEDICATED JELLY

S. Sabitha1 , Sushmita K2 , Kishan Pavani Jankuti3
1 Research Scholar, Chaitanya Deemed To Be University, Hyderabad, Telangana, India - 500081
2Assistant Professor, Vaageswari Institute of Pharmaceutical Sciences, Karimnagar, Telangana, India, 505481
3Assistant Professor, Vaageswari Institute of Pharmaceutical Sciences, Karimnagar, Telangana, India, 505481

Medicated jellies are semi-solid dosage forms designed to deliver drug through theoral route with improved patient compliance, especially for pediatric and geriatric patients. The demand for natural immunity-boosting formulations has increased significantly due to growing health awareness. In this study, we selected medicinal plants such as Carica papaya, Piperbetel, Withania somnifera and Morinda citrifolia. The medicated jellies were formulated using decoctions of Carica papaya (papaya) leaves and Piper betel (betel) leaves both known for immune modulatory and antioxidant properties. The natural sweetening agents are used such as sugarcanemolasses, stevia & jaggery. The jellies were prepared by heating and congealing method using natural gelling agents such as agar, gelatin and pectin. The prepared formulations were evaluated for physicochemical parameters including appearance, colour, odour, texture, pH, viscosity, syneresis, spreadability, invitro drug release. The physicochemical evaluation of the developed formulation has shown reddish brown colour, sweet pungent aroma, good spreadability, viscosity, syneresis, and pH almost near to saliva. The maximum amounts of % drug releaseof the formulations shown are F5-95.64%, F2-92.84%, F6-91.75%. So, theformulated jellies possess excellent potential as natural immunity boosters, their palatable taste and ease of administration. Further support is required to extend future clinical and toxicological validation for market applications.

## DEVELOPMENT AND EVALUATION OF VISMODEGIB LOADED TRANSFEROSOMAL GEL

A Ramakrishna Shabaraya, T Bhavyashree, Fmith Celvia Miranda, Mahananda Prabhu.
Srinivas College of Pharmacy Valachil, Mangalore, Karnataka.

The research focused on the development and evaluation of a vismodegib-loaded transferosomal gel for the treatment of basal cell carcinoma. Preformulation studies were initially conducted to assess drug-excipient compatibility and optimize formulation conditions. The transferosomes were prepared using the thin-film hydration method and optimized based on two key parameters: particle size and entrapment efficiency. A design of experiments (DoE) approach was employed and the results indicated that the formulation followed a linear model with respect to the selected parameters. The optimized transferosomal formulation underwent comprehensive physicochemical characterization, including vesicle size, polydispersity index, zeta potential, and drug loading. The transferosomal gel was further evaluated for pH, viscosity, spreadability, and homogeneity. Skin irritation studies confirmed the biocompatibility of the formulation. The results collectively suggest that the vismodegib transferosomal gel is a

ISBN: 978-81-980623-8-3

promising topical delivery system for the effective management of basal cell carcinoma.

**Keywords**: Vismodegib, transferosomes, thin-film hydration method, basal cell carcinoma

**APIGENIN LOADED PHYTOSOME FOR IMPROVED SOLUBILITY, DISSOLUTION AND ORAL BIOAVAILABILITY IN CANCER TREATMENT**

Aastha S. Yadav, Rashmi V. Trivedi, Anuvrat Sharma
Smt. Kishoritai Bhoyar College of Pharmacy kamptee Nagpur
Maharashtra India – 441002
yadavaastha20@gmail.com

Apigenin (APG) is a naturally occurring plant flavone (5, 7,-trihydroxyflavone) abundantly present in common fruits and vegetables including parsley, onions, oranges, tea, chamomile, wheat sprouts and some seasonings. APG has been shown to possess remarkable anti-inflammatory, antioxidant and anti-carcinogenic properties. Its clinical utility is limited by poor aqueous solubility, rapid, and low oral bioavailability, classifying it as a BCS Class II drug. In current research, formulation of apigenin-phospholipids complex (APLC) – loaded phytosome was developed with an aim of improving solubility and oral bioavailability of apigenin. The APLC was formulated using 1:1 – 1:5 ration of apigenin and Soybean phosphatidylcholin phospholipid using iono complex method followed by preparation of phytosome using lyophilization method. The APLC formation was supported by DSC, FTIR, 1H NMR, and PXRD analysis. The in vitro dissolution behavior of pure apigenin, and prepared APLC was analyzed using a dialysis method. The solubility of APLC in water increased as compared to pure apigenin. APLC also enhanced oral bioavailability of apigenin by demonstrating increased Cmax, Tmax, and AUC parameters as compared to apigenin. This study of optimized APLC formulation validates the value of employing phospholipids in preparing phytosome with phytoconstituents of low solubility to improve their solubility, oral bioavailability, and pharmacological properties.

**Keywords**: Apigenin, phospholipid, solubility, bioavailability, in vitro dissolution.

**FORMULATION, OPTIMIZATION AND CHARACTERIZATION OF IRBESARTAN AND TRIAMTERENE-LOADED MOUTH DISSOLVING ORODISPERSIBLE FILMS (MDODFS)**

Abhijeet Motiwale, Narendra Pratap Singh Sengar
Faculty of Pharmaceutical Sciences, Sanjeev Agrawal Global Educational University, Bhopal, (M.P.) – India
abhijeet@mcwhealthcare.com

Irbesartan, an angiotensin II receptor antagonist, and Triamterene, a potassium-sparing diuretic, were co-formulated to achieve synergistic antihypertensive effects and to minimize dose-related adverse effects. The films were prepared using the solvent casting method, employing pullulan as the film-forming polymer and polyethylene glycol 400 as the plasticizer, and suitable superdisintegrants agents to ensure rapid disintegration and palatability. The optimized was done by using Central Composite design by applying Design-Expert-13®. The prepared films were evaluated for physicochemical parameters such as thickness, weight uniformity, folding endurance, surface pH, tensile strength, and percentage elongation. Drug–polymer compatibility was confirmed using Fourier Transform Infrared Spectroscopy (FTIR) and Differential Scanning Calorimetry (DSC) analyses. Surface morphology was assessed by Scanning Electron Microscopy (SEM), indicating uniform distribution of both drugs without crystallization. The optimized film exhibited rapid disintegration within and a cumulative drug release of over 95% within 10 minutes, demonstrating its potential for fast onset of action. Stability studies conducted as per ICH guidelines confirmed the formulation's robustness with negligible changes in film characteristics and drug content over three months.

**Keywords**: Mouth Dissolving, Optimization, characterization

**DEVELOPMENT AND EVALUATION OF CO-PROCESSED EXCIPIENT AS SUPER-DISINTEGRANT IN MONTELUKAST ORAL DISINTEGRATION TABLETS**

Achanta Harika Devi, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
harikaachanta93@gmail.com

The objective of the study is synthesis of MCC–PCL co-processed excipient and improves the water uptake capacity of MCC, so as to improve the bioavailability of drug. Co-processed excipient was synthesized by reacting MCC with PCL in the presence of catalyst at elevated temperature. The prepared co-processed excipient has shown excellent flowability characteristics. Oral dissolving tablets of Montelukast sodium were prepared employing MCC-PCL co-processed excipient as superdisintegrant and comparison with commercial superdisintegrants. Total nine batches of oral disintegrating tablets were prepared using superdisintegrants like Crosscarmellose sodium (CCS), Sodium Starch Glycolate (SSG) and MCC–PCL Co-processed excipient by direct compression method. The results of precompression parameters were in acceptable range as per the specifications given in IP. Prepared tablets were evaluated for thickness, uniformity of weight, hardness, friability and the results are well within IP limits. Out of nine formulations, the tablets which contain 40 mg of co-processed excipient (F9) had shown low in vitro disintegration time 8 sec and highest drug release profile i.e. 98.72% which releases the drug within 12 minutes. After comparing its results with that of commercial superdisintegrants, it can be concluded that co-processed excipient can prove to be a good superdisintegrant and the developed Oral dissolving tablet formulation of Montelukast sodium could release the drug faster compared to conventional immediate release tablets which is useful in paediatric, geriatric and psychiatric patients.

**Keywords**: Co-processed excipient, Montelukast sodium, Superdisntegrents, Oral disintegrating tablets and Bioavailability

**DEVELOPMENT AND ASSESSMENT OF SUSTAINABLE PLA-BASED 3D-PRINTED MEDICAL DEVICES: AN INVESTIGATION INTO MECHANICAL INTEGRITY, BIOCOMPATIBILITY, AND BIODEGRADATION**

Apsara Unni, Kalirajan Rajagopal, S. Pranav Ragavendra
Department of Pharmaceutical Chemistry, JSS College of Pharmacy, Ooty, JSS Academy of Higher Education and Research, Mysuru, India
Department of Pharmaceutics, JSS College of Pharmacy, Ooty, JSS Academy of Higher Education and Research, Mysuru, India

Poly(lactic acid) (PLA) is a biobased and biodegradable polymer that is most notably used in additive manufacturing to create patient-specific medical devices, thereby providing high strength, precision, and an eco-friendly nature of degradation and thus a possible new application to replace petroleum-based materials in the medical field. This research project is focused on fabricating eco-friendly PLA-based 3D-printing medical devices and thereafter assessing their biomedical compatibility. The use of additive manufacturing processes has been leveraged in the creation of the design and PLA models and tensile strength measurements were conducted to verify the material performance under biologically relevant conditions. Moreover, the laboratory-based cytocompatibility experiments, animal testing, and biodegradation studies, which are all parts of the ongoing work, are aimed at establishing the material's safety, biological response, and environmental behaviour. The initial mechanical testing outcomes demonstrate that free-form fabricated PLA devices are strong enough and resilient to be used as medical devices while at the same time the material's renewable source and eco-friendly degradation further consolidate its adoption as a sustainable medical device solution. To sum up, PLA as a material could help medical devices to be more sustainable and thus has a strong potential to be the next-generation polymer in healthcare; however, long-term biocompatibility and degradation studies are still needed, and current results show that devices made of PLA can satisfy the functional clinical demands while being environmentally friendly.

[2]Department of Pharmaceutical Technology, Bharat Technology, Jadurberia, Uluberia, Howrah, West Bengal, India
apurikhi75@gmail.com

Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterized by joint inflammation, pain, and progressive disability. Although synthetic non-steroidal anti-inflammatory drugs (NSAIDs) provide symptomatic relief, their long-term use is associated with gastrointestinal and systemic side effects. Previously, a polyherbal gel containing extracts of Zingiber officinale, Allium sativum, Syzygium aromaticum, and Eucalyptus globulus demonstrated significant anti-inflammatory activity. However, limited transdermal permeation may restrict its therapeutic efficacy. The present study aimed to develop a nanoemulgel-based polyherbal formulation to enhance dermal penetration, stability, and anti-inflammatory activity for topical management of RA. The optimized nanoemulsion, characterized for droplet size, polydispersity index (PDI), and zeta potential, was converted into a gel using Carbopol 934. The resulting nanoemulgel was evaluated for pH, viscosity, spreadability, homogeneity, and in vitro drug diffusion through rat skin using Franz diffusion cells. Its anti-inflammatory efficacy was assessed. The optimized nanoemulgel exhibited a mean droplet size of <200 nm, stable zeta potential, and superior spreadability. In vitro and In vivo studies were performed as well which revealed significantly reduced paw edema, comparable to diclofenac gel. The developed polyherbal nanoemulgel demonstrated enhanced transdermal delivery and potent anti-inflammatory effects, indicating its potential as a safer and more effective herbal alternative for managing rheumatoid arthritis.
**Keywords**: Nanoemulgel; Polyherbal formulation; Rheumatoid arthritis—drug therapy; Anti-inflammatory agents, herbal; Transdermal absorption; Plant extracts—pharmacology

## GREEN TEA EFFERVESCENT GRANULES AS ANTIOXIDANT POTENTIAL REMEDY

Ashwini Bharati A1, Shete S1, Patil Pradnya1, Yadav Kajal1, Bhosale Dhanashree1, Vanita Kanase 1
1 AIMS College of Pharmacy, Vadavali, Dombivli (East), University of Mumbai

Taste is an important parameter in administering drugs orally. Undesirable taste is one of the important formulation problems that are encountered with many drugs. Administration of bitter drugs orally with acceptable level of palatability especially in children and the elderly is a key issue for health care providers. Proven methods for bitterness reduction and inhibition have resulted in improved palatability of oral formulations. Taste masking of obnoxious drugs has gained the importance in new era. This reason is an initiative for the development of various taste masking technologies by which the characteristics of the dosage form is improved and good patient compliance is achieved. Effervescent formulation is one of the taste masking solution. This formulation is a natural product containing a green tea plant extract in combination with other ingredients which create an effervescent liquid composition upon dispensing in a liquid. Certainly more interesting way of presentation is by dissolving in water and then will arise froth resulting from the release of CO2. This product is also relatively more stable in storage than in liquid form/ beverage in bottle. Carbonation produced can give freshness and cover unwanted taste. Green tea effervescent formulations are also more practical and easy to carry. Serving it also easy. Thus with this formulation, Polyphenols in green tea which are antioxidants bioflavonoids type that are 100 times more effective than vitamin C and 25 times more effective than vitamin E can be administered in accurate doses with ease.
**Keywords**: Effervescent formulation, Carbonation, Polyphenols, Vitamins.

## DESIGN AND DEVELOPMENT OF CYCLOSPORIN BASED COLLOIDAL CARRIER DRUG DELIVERY SYSTEM FOR TOPICAL MANAGEMENT OF ATOPIC DERMATITIS

Atharva B. Kurkute, Aryankumar Kadam, Amit B. Page, Mayank Sharma.
Department of Pharmaceutics, SVKM'S NMIMS SHIRPUR, MAHARASHTRA- 425405
kurkuteatharva@gmail.com

One of the common malignancies is skin cancer, which requires effective topical chemotherapy that has high skin penetration and low local side effects but, in many cases, its application is hampered by poor penetration to the skin. 5-Fluorouracil (5-FU) is a proven chemotherapeutic agent in the treatment of superficial skin cancer but its use is restricted by low penetration into the skin. To address this drawback, a dual-drug nanovesicular liposomal system of 5-FU and avobenzone, an extensive ultraviolet filter, has been designed and optimized to deliver therapeutic and protective effects on UV radiation. This study aimed at developing and testing a nanovesicular liposomal gel, which could be used in achieving better drug delivery and effective treatment of skin cancer. A 2 2 factorial design was used to optimize the nanovesicles to form spherical vesicles with an average diameter of about 150200nm, low polydispersity index and stable zeta potential (c. -30mV). FTTIR, UV spectral, HPLC characterization showed drug encapsulation and no drug-excipient interactions and encapsulation efficiency was more than 80. The optimized liposomal gel exhibited good viscosity, homogeneity and pH which was desirable in the application of dermals. The in vitro diffusion and skin permeation experiments have shown sustained release and greatly increased drug permeation characteristics in comparison to traditional gel preparations. The kinetics of release conformed to a Higuchi diffusion model whilst skin irritation experiments indicated very high dermal tolerability without erythema or edema.Finally, the resulting dual-drug nanovesicular liposomal gel is a chemotherapeutic agent which incorporates the photoprotective effect of avobenzone with excellent stability, skin diffusion, and prolonged release of the drug. The innovative solution is very promising as a safe and effective topical treatment of skin cancer, and it can be applied to a wide range of other dermatological diseases that would be treated and provided with UV protection simultaneously.
**Keywords**: 5-Fluorouracil, Avobenzone, Nanovesicular Liposomes, Liposomal Gel, Skin Cancer

**PC-977**

## DEVELOPMENT AND EVALUATION OF TARGETED LIPOSOMAL SYSTEM(S) FOR ANTICANCER DRUG DELIVERY

Balak Das Kurmi
Department of Pharmaceutics, ISF College of Pharmacy, Moga, Punjab, India, 142001
bdkurmi@gmail.com

This research focuses on the development and evaluation of targeted liposomal drug delivery systems to enhance the therapeutic efficacy of anticancer agents while minimizing systemic toxicity. Doxorubicin (DOX), a widely used chemotherapeutic agent, suffers from limitations such as multidrug resistance (MDR) and off-target toxicity. To address these challenges, two advanced liposomal formulations were designed: (i) HA-DOX-TPGS-LIPO, incorporating D-alpha-tocopheryl polyethylene glycol 1000 succinate (TPGS) and hyaluronic acid (HA) for CD44 receptor-mediated targeting, and (ii) TmAb-DOX-QCT-LIPO, a Trastuzumab-conjugated co-delivery system of DOX and quercetin (QCT) for HER2-targeted therapy and P-glycoprotein inhibition. Liposomes were prepared using the thin-film hydration method and optimised using Quality by Design (QbD) and Box-Behnken Design. The optimised formulations exhibited nanoscale vesicle sizes (~150-200 nm), low PDI, and negative zeta potential (15 to 17 mV), ensuring high stability and efficient drug encapsulation (%EE ≈ 80-82%). In vitro release studies demonstrated sustained drug release for up to 72 h, with HA-DOX-TPGS-LIPO showing slower, more controlled release than free DOX. MTT assay results revealed enhanced cytotoxicity of HA-DOX-TPGS-LIPO in MDA-MB-231 and MCF-7 cells, and of TmAb-DOX-QCT-LIPO in MCF-7/ADR cells, confirming superior efficacy over free drugs and non-targeted liposomes. Cellular uptake studies (FACS) indicated greater internalization of targeted liposomes through receptor-mediated endocytosis. Additionally, HA-DOX-TPGS-LIPO induced higher ROS generation and reduced NF-κB protein expression, suggesting apoptosis activation and suppression of survival pathways. Overall, both formulations effectively combined active targeting and demonstrated

ISBN: 978-81-980623-8-3

significant potential as advanced nanocarrier systems for improved breast cancer therapy.

**Keywords**: Liposomes, doxorubicin, hyaluronic acid, trastuzumab, quercetin, targeting

**DEVELOPMENT AND CHARACTERIZATION OF CHITOSAN BASED FLUTAMIDE NANOPARTICLES BY IONIC GELATION METHOD**

B. Pragna Sri, Sadhu Venkateswara Rao
Department of Pharmaceutics, Vijaya Institute of Pharmaceutical Sciences for Women, Enikepadu, Vijayawada, Andhra Pradesh, India – 521108
pragnasri597@gmail.com

The objective was to fabricate chitosan-based nanoparticles for better controlled and targeting action of drug, which also overcome the problems associated with conventional formulations like multidose therapy, poor patient compliance and high cost. Flutamide loaded chitosan nanoparticles (F1 to F6) were prepared by Ionotropic gelation method. The formulated nanoparticles were evaluated for external morphological characters, particle size analysis, zeta potential, drug content, entrapment efficiency and in-vitro release studies. The particle size varied from 148 to 317 nm and zeta potential was in negative and its value found to be - 46.4 mV. The drug content for the Flutamide loaded chitosan nanoparticles varied from 69.5 ± 7.2 % to 87.9 ± 1.2 %. The entrapment efficiencies were found to be minimum and maximum of 55.50 ± 2.4 % and 86.30 ± 3.6 %. The percentage yields of all formulations were in the range of 48.24 ± 1.24 to 86.13 ± 1.37 %. In-vitro release of drug showed sustained release behaviour for a period of 24 hr. The optimized formulation contains 3:1 ratio of chitosan & STTP and demonstrated successful sustained release. Flutamide loaded chitosan nanoparticle is a potential new delivery system for treatment of prostate cancer.

**Keywords**: Prostate Cancer, Chitosan nanoparticles and Ionic gelation method.

Neuroinflammation is a central hallmark in the progression of numerous neurodegenerative disorders. Berberine, a bioactive isoquinoline alkaloid, exhibits remarkable neuroprotective and anti-inflammatory potential; however, its therapeutic application is hindered by poor solubility, low systemic bioavailability, and limited brain penetration. To overcome these pharmacokinetic barriers, a polymeric nanoparticle-based drug delivery system is being designed to enhance the stability, bioavailability, and targeted delivery of berberine to the central nervous system. Preliminary formulation studies have been undertaken using biocompatible and biodegradable polymers to encapsulate berberine through optimized nanoparticle fabrication techniques such as solvent evaporation and nanoprecipitation. The formulated berberine-loaded polymeric nanoparticles exhibited a mean particle size of 184 nm with a polydispersity index (PDI) of 0.343, confirming a narrow and uniform particle size distribution. The zeta potential was recorded as 24.2 mV, indicating good colloidal stability and surface charge properties. The encapsulation efficiency (EE%) was 86%, signifying efficient drug entrapment within the polymeric matrix. The in vitro release study revealed a cumulative drug release of 92%, demonstrating a sustained and controlled release profile over the evaluation period. These findings collectively suggest that the developed nanoformulation enhances drug stability, bioavailability, and release performance compared to free berberine. The preliminary outcomes highlight that polymeric nanoparticle encapsulation offers a promising and innovative approach to enhance berberine's therapeutic potential in combating neuroinflammation associated with neurodegenerative disorders. Ongoing studies aim to further optimize the formulation and evaluate its in vitro and in vivo neuroprotective efficacy to establish it as a viable nanotherapeutic strategy for neuroprotection.

**DEVELOPMENT & EVALUATION OF A LONG ACTING INJECTABLES DEPOT FORMULATION OF RISPERIDONE USING PLGA MOCROSPHERES**

Bezawada Swarna mani, Inturi Venkata Rama Rao
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
bezawadaswarnamani@gmail.com

Risperidone is a widely used antipsychotic medication for the treatment of schizophrenia and bipolar disorder. However, its short half-life and frequent dosing requirements can lead to poor patient compliance. To address this issue, a long-acting injectable depot formulation of risperidone was developed using poly(lactic-co-glycolic acid) (PLGA) microspheres. The microspheres were prepared using an oil-in-water emulsion solvent evaporation technique and optimized for particle size, encapsulation efficiency, and in vitro release profile. The optimized formulation exhibited a mean particle size of 50 µm, an encapsulation efficiency of 85%, and a sustained release of risperidone over 4 weeks. In vivo pharmacokinetic studies in rats showed that the depot formulation maintained therapeutic plasma concentrations of risperidone for 28 days, with a significant increase in bioavailability compared to the oral formulation. The formulation was also found to be stable and safe, with no signs of toxicity or inflammation at the injection site. These results suggest that the PLGA microsphere-based depot formulation of risperidone has the potential to improve patient compliance and treatment outcomes for schizophrenia and bipolar disorder.

**Keywords**: Risperidone, PLGA microspheres, Depot formulation, Long-acting injectable, Schizophrenia, Bipolar disorder.

bhargavidronavalli2466@gmail.com

Mucoadhesive buccal films offer a promising, non-invasive drug delivery system aimed at enhancing the bioavailability of drugs that undergo extensive first-pass metabolism. This study focused on the formulation and evaluation of buccal films for drug Rizatriptan used in the management of migraine. Drugs that undergo extensive first-pass metabolism often exhibit reduced bioavailability, limiting their therapeutic effectiveness. Mucoadhesive buccal films provide a non-invasive and efficient drug delivery system that bypasses hepatic metabolism, offering faster onset of action, enhanced bioavailability, and improved patient compliance. Rizatriptan, a serotonin receptor agonist. Buccal films (F1–F4). were prepared using the solvent casting method with a blend of hydroxypropyl methylcellulose (HPMC), and Eudragit RS100. The prepared formulations were tested for various physicochemical properties viz., folding indurance, weight variation, assay, drug content. These films were also evaluated for mechanical strength, mucoadhesive properties, swelling behaviour, and drug release profile. Among the formulations, F1 demonstrated superior performance with a complete drug release profile along the semi-permeable membrane, using Franz-diffusion cell. In vitro studies indicated that F1 showed the highest drug release profile using semi-permeable membrane. It also exhibited excellent physicomechanical properties, consistent drug content, and drug release (95%in 24 hours). The results confirm that buccal film formulations of rizatriptan offer a patient-friendly and effective alternative to oral delivery, improving therapeutic outcomes and potentially increasing patient compliance for drugs with poor oral bioavailability.

**Keywords**: Mucoadhesive buccal films, Hydroxypropyl methylcellulose (HPMC), physicochemical properties, Eudragit RS100.

ISBN: 978-81-980623-8-3

**FORMULATION AND EVALUATION OF BERBERINE LOADED CUBOSOMAL NANOFORMULATION FOR THE TOPICAL TREATMENT OF ACNE**

Bhaskar Kurangi1, Sunil Jalalpure1, Anjali Bawadekar1, Madhuri Sankpal1
1 KLE College of Pharmacy Belagavi, KLE Academy of Higher Education and Research, Belagavi- 590010, Karnataka, India.

This study aimed to formulate, optimize and evaluate a novel Berberine-loaded cubosomal gel (BC-Gel) for the topical treatment of acne vulgaris, leveraging the antimicrobial and anti-inflammatory potential of Berberine and the dermal delivery advantages of cubosomes. Cubosomes were prepared using a top-down homogenization approach and optimized via a $3^2$ factorial design, with glyceryl monooleate and Poloxamer 407 as critical variables. The optimized formulation (BC5) was characterized for particle size, entrapment efficiency, zeta potential, and morphology. BC5 formulation was incorporated into a Carbopol 934-based gel and assessed for pH, viscosity, drug content, in vitro diffusion, and ex vivo skin permeation. Antibacterial activity against Propionibacterium acnes (P. acnes) was evaluated using MIC and MBC assays. In vivo efficacy was assessed in a P. acnes-induced acne model in Wistar rats, supported by histopathological analysis and skin irritation studies. The optimized BC5 formulation demonstrated a particle size of 130 nm, Polydispersity index of 0.24, and 73.28% entrapment efficiency. The cubosomal gel showed controlled drug release (81.26% over 24 hours) and superior ex vivo skin permeation (76.10%) compared to plain Berberine gel. BC5-Gel exhibited potent antibacterial activity (MIC: 500 µg/mL; MBC: 1000 µg/mL) and significantly reduced ear inflammation in vivo. Histopathology confirmed reduced inflammatory infiltration, and the formulation was non-irritant in skin tolerability studies. BC5-Gel demonstrated enhanced topical delivery, antimicrobial efficacy, and safety, positioning it as a promising candidate for acne management. The cubosomal nanocarrier system significantly improved the bioavailability and therapeutic performance of Berberine for dermal applications.

**Keywords**: Berberine, cubosomes, acne vulgaris, topical delivery, antimicrobial, Propionibacterium acnes, skin permeation, cubosomal gel.

**PC-983**

**FORMULATION AND EVALUATION OF BILAYER FLOATING TABLETS OF PITAVASTATIN AS IMMEDIATE RELEASE LAYER AND PROPRANOLOL AS SUSTAINED RELEASE LAYER**

Bhosale Dattatray Gopichand
Department of Pharmaceutics, Swami Ramanand Teerth Marathwada University, Nanded, Maharashtra, India, 431606
dattatraybhosale375@gmail.com

The aim of the present research work is to design, formulate, and evaluate a bilayer tablet containing Pitavastatin calcium as an immediate release (IR) layer and Propranolol hydrochloride as a sustained release (SR) layer for the effective treatment of hyperlipidemia associated with hypertension. Pitavastatin, a lipid-lowering agent, provides a rapid onset of action, while Propranolol, a β-blocker, offers prolonged antihypertensive activity. The bilayer approach minimizes dosing frequency and enhances patient adherence by combining two drugs in a single dosage form. The IR layer was formulated using superdisintegrants (Crospovidone and Sodium Starch Glycolate) for rapid drug release, whereas the SR layer was developed using HPMC K100M and Carbopol 974P as matrix-forming polymers to achieve controlled drug release. Preformulation studies such as solubility analysis, drug–excipient compatibility (FTIR and DSC), and micromeritic evaluations were conducted to ensure formulation stability. The bilayer tablets were evaluated for hardness, friability, thickness, weight variation, drug content, buoyancy, and in-vitro dissolution profile. Results showed that the optimized formulation achieved rapid release of Pitavastatin within 30 minutes and sustained release of Propranolol up to 12 hours, following Higuchi kinetics. The developed bilayer system demonstrated excellent mechanical integrity, desired floating behavior, and controlled drug delivery, providing a novel and patient-friendly approach for the combined management of cardiovascular diseases.

**Keywords**: Bilayer tablet, Pitavastatin, Propranolol, Sustained release, HPMC, Cardiovascular therapy.

**PC-984**

**FORMULATION DEVELOPMENT AND CHARACTERIZATION OF LECARNIDIPINE HYDROCHLORIDE NIOSOMAL TRANSDERMAL PATCHES**

B. Padmaja1, S. Shobha Rani2, R. Ramakrishna1
1Department of Pharmaceutics, Vaageswari Institute of Pharmaceutical Sciences, Karimnagar,505527, Telangana, India.
2Jawaharlal Nehru Technological University Hyderabad, Kukatpally, Hyderabad,500085, Telangana, India.

The bioavailability of Lercanidipine Hydrochloride (LCP) is about 44% and half-life of the drug is about 4.6 hours. LCP due to its low therapeutic dose range of 2.5 to 20mg and substantial biotransformation in liver becomes it ideal molecule in development of transdermal therapeutic system. The primary objective of the present research work was to develop Niosomaltransdermal patch (NP)of Lecarnidipine. The LCP nanoparticles were prepared by solvent evaporation method and the optimized Nanoparticles formulation has shown 225nm particle size with a polydispersity index (PDI) of 0.120. LCP patches were prepared by incorporating nanoparticles dispersion, using varying concentrations of polymers HPMC E5, HPMC 5cps, HPMC 15cps, Carbopol 734 and Sodium alginate using solvent casting techniques and further optimized by central composite design(CCD) the effect of polymer on the various physico-chemical characteristics and in-vitro drug release studies, ex-vivo skin permeation studies is studied. On the basis of in-vitro drug release and ex-vivo skin permeation studies, the formulation containing (HPMC 15cps and HPMC 5cps) has shown sustained and extended drug release over a period of 24 hrs.

**Keywords**: Lecarnidipine; Niosomes; Transdermal patch; Central composite Design, Controlled release; Bioavailability etc.

**DEVELOPMENT AND CHARACTERIZATION OF LIPOSOMAL FORMULATION OF CEREUS JAMACARU EXTRACT FOR ENHANCED BIOAVAILABILITY**

Boya Indra Kumar, P. Venkata Durga Seshu Priya
Pharmaceutics Department, Jagan's institute of pharmaceuticals sciences, Nellore, Andra Pradesh, India
lovelyindrakumar143@gmail.com

Herbal medicines have gained increasing attention for their therapeutic potential, but their use is often limited by poor solubility, instability, and low bioavailability of active constituents. Cereus jamacaru, commonly known as the mandacaru cactus, is rich in flavonoids, alkaloids, and phenolic compounds that exhibit antioxidant, anti-inflammatory, and antimicrobial activities. However, its pharmacological efficacy is restricted due to rapid degradation and limited absorption. The present study focuses on the development and characterization of a liposomal formulation of Cereus jamacaru extract to enhance its stability and bioavailability. Liposomes were prepared using the thin film hydration technique with phosphatidylcholine and cholesterol as major components. The formulated liposomes were evaluated for particle size, zeta potential, encapsulation efficiency, morphology (using SEM/TEM), and in vitro release profile. The optimized formulation exhibited a mean particle size below 200 nm, zeta potential of -35 mV, and high encapsulation efficiency (>80%), indicating good stability and uniform vesicle formation. The in vitro release studies demonstrated a sustained and controlled release pattern compared to the free extract. Stability testing confirmed that the liposomal encapsulation protected the phytoconstituents from degradation under various storage conditions. The study concludes that liposomal encapsulation of Cereus jamacaru extract significantly improves its stability, solubility, and bioavailability, offering a promising strategy for developing effective herbal nanocarrier-based drug delivery systems with enhanced therapeutic potential.

**Keywords**: Cereus jamacaru, Mandacaru cactus, Liposomes, Phytoconstituents, Herbal drug delivery, Bioavailability enhancement, Thin film hydration, Encapsulation efficiency, Zeta potential, Nanocarrie, Stability studies, In vitro release, Flavonoids, Phosphatidylcholine, Cholesterol

**FORMULATION AND EVALUATION OF SUBLINGUAL TABLETS OF MECLIZINE HYDROCHLORIDE**

Boyina poojitha, Pisipati Aparna

ISBN: 978-81-980623-8-3

Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
poojithaboyina@gmail.com

The present study aims to formulate and evaluate sublingual tablets of Meclizine Hydrochloride using direct compression method to enhance bioavailability and provide rapid therapeutic action. Meclizine Hydrochloride, a first-generation antihistamine (non-selective H1 antagonist), is widely used in the treatment of nausea, vomiting, and vertigo. However, its therapeutic efficacy is limited by poor water solubility and extensive first-pass hepatic metabolism via CYP2D6 enzymes, leading to reduced systemic availability.To overcome these limitations, a sublingual formulation was developed to enable direct absorption through the highly vascularized sublingual mucosa, bypassing hepatic metabolism and allowing for a faster onset of action. Drug solubility was enhanced by forming inclusion complexes with β-cyclodextrin using the kneading method. Meclizine Hydrochloride and β-cyclodextrin were triturated with a small volume of solvent, kneaded thoroughly, dried, and sieved to obtain a uniform complex. These complexes were then blended with suitable excipients and directly compressed into tablets. The sublingual tablets was tested for post compression parameters like weight variation, hardness, friability, rapid disintegration, improved solubility, and enhanced patient compliance, especially for those experiencing difficulty in swallowing or requiring immediate relief. The drug release profile showed that over 85% of Meclizine Hydrochloride was released within 15 minutes, indicating rapid onset of action This study concludes that sublingual Meclizine Hydrochloride tablets represent a promising alternative to conventional oral dosage forms for effective and rapid antiemetic therapy.

**Keywords**: Sublingual tablets, Vertigo, Antiemetic therapy.

**PC-987**

**FORMULATION, DEVELOPMENT AND INVITRO EVALUATION OF BUCCAL DISSOLVING TABLETS OF PIROXICAM**

Bramani Goud, Kantlam Chamakuri
Department of Pharmaceutics, Brilliant Grammer Group of Institutions, Hyderabad, Telangana, India.
Bramani.goud05@gmail.com

Buccal dissolving tablets of piroxicam were prepared by using HPMC K4M and carbopol 934 as mucoadhesive polymers. Ten formulations were developed with varying concentrations of polymers. H1 to H5 formulations were composed of HPMC K4M in ratios of 1:1 to 1:5 whereas in C1 to C5 formulations Carbopol 934 were used in ratios of 1:0.25 to 1:1.5. The formulations were tested for in-vitro drug release, bioadhesive strength, moisture absorption, residence time and drug permeation through porcine buccal mucosa. Optimized formulation H3 showed maximum release of the drug (97.67±0.41) with the peppas model release profile and permeated 26.52±0.19 of the drug through porcine buccal membrane. H3 formulation showed 12.5gm of mucoadhesive strength, the FTIR results showed no evidence of interaction between the drug and polymers. The results indicated that suitable bioadhesive buccal tablets with desired permeability could be prepared. Stability of piroxicam buccal tablets was determined in natural human saliva; it was found that both piroxicam and buccal tablets were stable in human saliva.

**Keywords**: Piroxicam, Buccal tablets, Formulation & Evaluation.

nagasurender7@gmail.com

Bioelectronic medicine (also called, electroceuticals) use miniaturized electronic devices to therapeutically disrupt the nervous system—by targeting specific neural circuits (e.g. the inflammatory reflex, vagus nerve), electroceuticals can have fewer side effects than traditional systemic pharmacology. The classical family of stimulators (pacemakers, cochlear implants) are being surpassed by closed-loop systems that can provide real-time sensing of physiological alterations. In this paper we provide a summary of the existing clinical applications of electroceuticals (neurological, cardiac, pain, metabolic, and immune disorders), a survey of the history of electroceuticals, and a description of the possible technologies enabling bioelectronic medicine (both invasive and non-invasive therapeutics). We report some of the technical and translation issues (biocompatibility, reliability, power, and regulatory) and potential enabling technologies: wireless interfaces, flexible “soft” implants, intelligent closed-loop programming. We also briefly speculate on potential developments in materials science, machine learning, and systems medicine that may bring personalized neurotherapies and bioelectronic platforms.

**Keywords**: Bioelectronic medicine; Electroceuticals; Neuromodulation.

**INTRANASAL ADMINISTRATION OF DOXEPIN: IMPROVING BRAIN TARGETING EFFECTIVENESS BY EMPLOYING NANOSTRUCTURED LIPID CARRIERS WITHIN A BIOPHARMACEUTICS DRUG DISPOSITION CLASSIFICATION SYSTEM, CLASS-I DRUG.**

Darshan Thakare, Aayushi V. Vasandia
School of Health Sciences and Technology, Dr. Vishwanath Karad MIT World Peace University, MIT Campus, Kothrud, Pune - 411038, Maharashtra, India.
darshanthakare2212@gmail.com

Doxepin, classified under Class I in the Biopharmaceutics Drug Disposition Classification System (BDDCS), has limited bioavailability due to significant first-pass metabolism. This study aims to improve the delivery of doxepin by developing nanostructured lipid carriers (NLCs) using the Box–Behnken Design method. These optimized NLCs are designed for administration via the nasal route, with the primary objective of enhancing drug delivery from the nose to the brain. The formulation of NLCs was carried out using a high-speed homogenization method. The optimized formulation exhibited a small particle size (75.80±5.48nm, PDI ¼ 0.286), a high entrapment efficiency (94.10 ±0.16%), and a sustained ex vivo release profile (82.25±4.61% at 24 hours). Characterization analyses indicated that doxepin was transformed from a crystalline form to an amorphous state, achieving a uniform distribution within the lipid matrix. In vivo pharmacokinetic assessments in rats revealed markedly higher concentrations of doxepin in brain tissue (C max intravenous administration (C ¼ 16.77mg/g, t max ¼ 2.53mg/g, t ¼ 30min) following intranasal administration relative to (C max ¼ 6h). The high drug targeting efficiency (DTE ¼ 284.3%) and the percentage of direct transport (DTP ¼ 64.8%) indicated effective penetration of NLCs into the brain through the olfactory and trigeminal pathways. In summary, the study demonstrates the promise of NLCs to enhance the bioavailability of doxepin via nose-to-brain delivery, potentially facilitating the management of neurological disorders.

**Keywords**: Doxepin; Box–Behnken design; nanostructured lipid carriers; nose-to-brain; bioavailability; pharmacokinetic study

**BRIDGING INNOVATION AND INTEGRITY: A HOLISTIC APPROACH TO SUSTAINABILITY IN THE COSMETICS INDUSTRY**

Solomon D, M P Venkatesh, Rafiq M and T M Pramod Kumar
Centre of Excellence in Regulatory Sciences, Department of Pharmaceutics, JSS College of Pharmacy, JSS Academy of Higher Education and Research, SS Nagar, Mysuru - 570015, Karnataka
cptsolomon@gmail.com

Sustainability within the cosmetic industry is naturally multidimensional: It ranges from environmental stewardship, through technological advancement and regulatory governance, to evolving consumer expectations. This review synthesizes insights from recent literature and case analyses to illustrate how genuine progress requires action coordinated across all parts of the product life cycle-from responsible ingredient sourcing and green formulation design through sustainable manufacturing, ethical distribution, to effective end-of-life management. Amongst these, technological innovations have proved to be key enablers of sustainability through the adoption of green chemistry, biotechnological development, and process optimization. These have enabled reduced reliance on petrochemical derivatives, minimized adverse environmental impacts, and ensured a high level of safety and effectiveness. Simultaneously, regulatory frameworks have provided

ISBN: 978-81-980623-8-3

strategic guidance to industry transformation through compliance, transparency, and accountability. Global environmental standards, voluntary certification, and life-cycle assessment methodologies furthered the need to integrate the principles of sustainability into corporate strategy and product development. Today's consumer seeks authenticity, traceability, and verifiable data that prove actual impact. Sustainability attributes, like the use of naturally derived or responsibly sourced ingredients, recyclable or refillable packaging, ethical labor practices, and measurable reductions in environmental footprint, have emerged as key drivers of consumer brand trust, loyalty, and purchasing behavior. The evidence, then, confirms that genuine sustainability in cosmetics needs to be science-driven, transparent, and inclusive of all stakeholders. They embed measurable goals on sustainability, adopt mechanisms for transparent reporting, and continuously innovate toward lower-impact products.

## FORMULATION AND EVALUATION OF CIPROFLOXACIN IN-SITU GEL

Dimmiti Jaswanth, Inturi Venkata Rama Rao
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
dimmitijaswanth@gmail.com

The study aimed to formulate and evaluate a gastro-retentive in situ gel of ciprofloxacin for improved drug delivery. The in-situ gel was prepared using a combination of natural and synthetic polymers, and the effects of different concentrations of sodium alginate, HPMC K-100, and calcium carbonate on viscosity and drug release over 8 hours were examined. The prepared formulations were evaluated for various parameters, including appearance, pH, viscosity, buoyancy, gelling capacity, swelling index, drug content, and in vitro drug release. The in-situ gel exhibited desirable physicochemical properties and a prolonged drug release profile. All formulations demonstrated optimum viscosity, ensuring ease of administration and swallowing. The floating lag time of the formulations ranged from 43 to 75 seconds, and all floated for more than 12 hours. The in vitro gelling capacity increased with rising concentrations of sodium alginate and calcium carbonate. Formulation F6 showed a high swelling index, indicating its capability to absorb a large amount of fluid. The in vitro drug release from these in situ gels was slow, extended, and dependent on the concentration of sodium alginate and HPMC K-100. The formulation F6, containing 1.25% sodium alginate and 2% HPMC K-100, exhibited sustained in vitro drug release of 67.23% over 12 hours. The drug release from formulation F6 followed first-order kinetics. Therefore, the gastro-retentive in situ gel of F6 can be considered a promising drug delivery system for enhancing the bioavailability and therapeutic efficacy of ciprofloxacin, highlighting the potential of in situ gel-based drug delivery systems.

**Keywords**: Gastro retentive, In situ gel, Floating time, In-vitro drug release and Ciprofloxacin.

## ENHANCING SOLUBILITY AND BIOAVAILABILITY OF A POORLY WATER-SOLUBLE DRUG USING AMORPHOUS SOLID DISPERSIONS: PREPARATION AND CHARECTERIZATION

Dommeti Hema Bramarambika, Inturi Venkata Rama Rao
Department of Pharmaceutics, NRI College of Pharmacy, Pothavarappadu, Agiripalli Mandal, Eluru District, Andhra Pradesh, India -521212.
hemabramarambika@gmail.com

Amorphous solid dispersions (ASDs) are a promising approach to enhance the solubility and bioavailability of poorly water-soluble drugs. In this study, ASDs of itraconazole were prepared using hot melt extrusion (HME) and spray drying with Soluplus, Kollidon VA64, and Eudragit EPO. The formulations were characterized using differential scanning calorimetry (DSC), X-ray powder diffraction (XRPD), Fourier transform infrared spectroscopy (FTIR) and scanning electron microscopy (SEM). All ASDs showed significantly improved solubility and dissolution compared to crystalline itraconazole. Among them, Soluplus-based ASD exhibited the highest enhancement, achieving a 10-fold increase in solubility. Physical stability studies under accelerated conditions (40 °C/75% RH) for 6 months confirmed that all ASDs remained amorphous without recrystallization or degradation. In vitro dissolution studies further demonstrated rapid drug release, with ASDs releasing over 80% of the drug within 30 minutes, whereas the crystalline drug released less than 10% in the same period. Dissolution data fitted to kinetic models, including the Korsmeyer-Peppas model, indicated a predominantly diffusion-controlled drug release mechanism. In vivo pharmacokinetic evaluation in rats showed that the Soluplus ASD resulted in a 5-fold increase in oral bioavailability compared to the crystalline drug. This improvement was attributed to enhanced solubility and faster dissolution. Overall, the findings indicate that ASDs prepared by HME and spray drying, particularly with Soluplus, offer an effective strategy for improving solubility, dissolution rate, and bioavailability of poorly water-soluble drugs such as itraconazole.

**Keywords**: Amorphous solid dispersion, Soluplus, Hot melt extrusion, Spray drying, Itraconazole, Solubility, Bioavailability

## FORMULATION, CHARACTERIZATION AND EVALUATION: MICELLAR LOADED COMPLEX OF CUMINUM CYMINUM TO TREAT CAUSING DISEASE OF RESPIRATORY INFECTION

Rudra Pratap Singh Rajput 1, H. V. Gangadharappa2, Deepak Kumar Dash1
Department of Pharmaceutics,
1Royal College of Pharmacy, Raipur – 492099, Chhattisgarh, India.
2JSS Academy of Higher Education & Research, Mysuru - 570015, Karnataka, India
rudra.p.s007@gmail.com

Respiratory infection (RTI) is a viral spreading disease and it transmits from individual to individual, particularly in youngsters and aged peoples. The treatments are available but have so many limitations. To overcome these issues, novel drug delivery (nanoparticle) based micellar loaded complex approach was adopted using cuminaldehyde (Cuminum Cyminum L.). In this study, the micellar (CM) was prepared by mixing of cuminaldehyde and soya lecithin using anti-solvent precipitation technique and further the micellar loaded complex (CMLC) was prepared by loading of micellar (CM) in aqueous solution of chitosan. The optimized CMLC and CM were irregular particle shapes and crystalline structures, with a mean particle size of 279.10±0.02 nm, 296.24±0.10 nm and zeta potential of -8.18 mV, -8.77 mV, respectively. The % entrapment efficiency and % drug loading of CMLC (72.13±0.26 %, 06.46±0.01 %) and CM (89.09±0.20%, 08.05±0.19 %) was found efficiently. The in vitro release rate of CM (88.09±0.41 %) was slower than CMLC (89.02±0.06 %) in pH 7.4 phosphate buffer up to 24 h by diffusion process (Korsmeyer Peppas model). Furthermore, CMLC has shown the potent in vitro antioxidant activity, susceptible antibacterial activity and significant anti-inflammatory activity as compared to CM against stress, microbial infection (S. aureus and E. coli) and inflammation which were causable reason for the respiratory infections. CLMC has shown the significant bioavailability and more efficient hematological parameters value on rabbit blood against the incubation of bacterial organism. CLMC may have the effective potential to treat causing disease of COVID 19 i.e. RTI.

**Keywords**: Respiratory infection (RTI), cuminaldehyde, Micellar, Evaluation Parameters.

Microspheres have emerged as an efficient drug delivery system capable of improving the stability and bioavailability of therapeutic agents, particularly those with poor solubility or susceptibility to degradation. The present study focuses on the formulation and comprehensive characterization of drug-loaded microspheres designed to enhance drug stability and achieve sustained release. Microspheres were prepared using a polymer-based encapsulation technique, and their physicochemical properties were evaluated through particle size analysis, surface morphology, drug entrapment efficiency, and in vitro

ISBN: 978-81-980623-8-3

drug release studies. The optimized formulation exhibited spherical, uniformly dispersed particles with controlled size distribution and high encapsulation efficiency. Stability studies demonstrated significant protection of the drug against environmental degradation, while release kinetics revealed a sustained and predictable release profile. The results indicate that microsphere-based delivery offers a promising strategy to improve the therapeutic performance of unstable and poorly bioavailable drugs. This approach can be effectively utilized for oral, parenteral, and targeted drug delivery applications.

The present study focuses on the development and evaluation of pH-sensitive polymeric microspheres for the oral delivery of Metformin Hydrochloride, aiming to achieve controlled drug release and improved gastrointestinal retention. Metformin, a first-line antidiabetic agent, exhibits short half-life and poor gastrointestinal absorption, necessitating frequent administration. To overcome these limitations, pH-sensitive microspheres were formulated using Eudragit S100 and Eudragit L100 as enteric polymers through the emulsion solvent evaporation method. The prepared microspheres were evaluated for particle size, entrapment efficiency, surface morphology, swelling index, and in-vitro drug release at varying pH conditions. The optimized formulation exhibited a mean particle size of 150–200 µm and drug entrapment efficiency of 85.2 ± 1.6%. In-vitro release studies showed minimal drug release in acidic medium (pH 1.2) and a sustained release over 10 hours in phosphate buffer (pH 6.8), confirming the pH-responsive behaviour. The release kinetics followed the Korsmeyer–Peppas model, indicating non-Fickian diffusion. Stability studies revealed no significant changes in drug content or morphology. The study concludes that the pH-sensitive polymeric microspheres provide an effective oral delivery platform for Metformin Hydrochloride, enhancing therapeutic efficacy and patient compliance through sustained and site-specific release.

Diabetes mellitus currently remains one of the significant burdens of global health, which often necessitates long-term pharmacotherapy in order to maintain optimum glycemic levels. Linagliptin is potent DPP-4 inhibitor that exhibits favorable pharmacodynamic properties but poor aqueous solubility, which may reduce its bioavailability. The present study aimed at the formulation and optimization of the linagliptin nanosuspension with a view to enhancing its dissolution rate and therapeutic efficacy. In this study, a high speed homogenization technique were used and stabilizing agent such as STPP were added to produce a stable nanosuspension with minimum particle aggregation. After preparing nanoparticles it was subjected for evaluation test in which Particle size, PDI, Zeta potential , Entrapment efficiency were carried out and it observed that all the parameter are in acceptable range. Physical characterization showed that the optimized formulation had a mean particle size in the nanometer range, with narrow polydispersity index and an improved zeta potential, indicating high physical stability. In-vitro dissolution studies revealed significantly higher drug release compared with the pure drug, thus confirming improved solubility. Preliminary in-vivo evaluation further established enhanced antihyperglycemic activity in diabetic models. Conclusively, the linagliptin nanosuspension is a promising nanotechnological approach toward enhancement of oral bioavailability and therapeutic outcomes in diabetes mellitus management.

Fluconazole is a broad-spectrum antifungal agent that has been extensively applied for the management of oral, pharyngeal and cutaneous candidiasis. In the present study, it was aim to prepare and evaluate buccal film as a controlled release carrier for fluconazole. The formulation was intended to provide localized delivery of fluconazole exclusively at the site of infection, thereby reducing its total dose and hence, dose related toxicities. Buccal films were prepared by solvent casting method using sodium alginate and HPMC K - 100 alone as well as in various combinations. Prepared films were evaluated for physical characteristics like, weight and content uniformity, film thickness, swelling index, microenvironment pH and folding endurance and in vitro drug release. The result showed that weights of formulations were ranging from 0.0220.031gm. to 0.042 0.051 gm. This indicates that there was no significant weight variation in all formulations. Thickness of the buccal films varied between 0.3150.07 mm to 0.4450.02 mm. The maximum moisture uptake from F7 films may be due to the high concentration of hydrophilic polymer HPMC, which readily absorbs moisture when exposed to atmosphere. Microenvironment pH was near to 7.0 for all of the formulations. In vitro drug release was tested and it provided controlled drug release up to 8 hr.

**Keywords**: Fluconzole, Buccal films, Controlled release and In vitro drug release.
